ARTS AND SCIENCES.

RELICS (in Latin, "reliquiæ") is a term used to signify the remains, bones, or garments of departed holy men, which are honoured by the followers of the Church of Rome. During the early ages of the Christian Church, martyrs were held in veneration; and their relics were treasured up as something sacred. The anniversary of their martyrdom was celebrated by assemblies of the faithful, held round their tomb or on the places where they had perished, and chapels and sanctuaries were raised on the spot. In the 4th and 5th centuries the previous veneration for the saints became a kind of worship; miracles were said to be performed by fragments of their bones or garments, and pilgrimages were undertaken to obtain these relics. Helena, the mother of Constantine, went to Palestine, and was said to have found the identical cross on which Christ suffered. The employment of images and that of relics as accessories to church worship seem to have grown up together during that period. Towards the end of the 6th century, Pope Gregory I. displayed a great veneration for relics. There is a letter of his to the empress Constantina, who had asked him for a part of the body of St. Paul, in which he excuses himself by saying that it was not the custom of the Romans, and, in general, of the Christians of the West, to touch, much less to remove the bodies of saints; but that they put a piece of linen called "brandeum" near the holy bodies, which is afterwards withdrawn, and treasured up with due veneration in some new church, and as many miracles are wrought by it as if the bodies themselves were there: he adds that they were much surprised at the Greeks removing the bones of saints from place to place; but that in order not to disappoint the piety of the empress, he would send her some filings of the chains which St. Paul wore on his neck and hands. This letter is quoted by Baronius, Fleury, and other church historians. From that time the veneration for relics increased, but there was no longer the same scrupulosity about removing the relics. Relic worship became during the middle ages a vulgar superstition and disgraceful traffic; and the abuse has been censured by many sincere Roman Catholics. It was ordered by several synods that no relics should be exposed to view without the sanction of the local bishop. Pope Innocent III. forbade the sale of relics. The Roman Catholic Church however admits that the relics of saints have performed and may still perform miracles; and that they are a proper object of veneration.

(*Bibliothèque Sacrée, par les Pères Richard et Giraud,* articles 'Reliques' and 'Saints,' 3rd section, 'Reliques des Saints;' and also Father Honoré de Sainte Marie, *Dissertation sur les Reliques;* and the Abbé de Cordemoi, *Traité des Saintes Reliques.*)

RELIEF, RELEVIUM, a burden incident to feudal tenures, being a sum of money paid to the lord on the admittance of a fresh tenant. It is a relic of that state of things in which the succession was not strictly speaking of right, but at the will of the lord, who required the payment of such an acknowledgment for the concession. It became however so much the custom for the lords to admit the sons or near kindred (heirs, as we now say) to the inheritance of the ancestor, that a custom became established of doing so, and out of the custom grew the right. The money however which had been paid for admission in the former state of things, continued to be paid when the succession of the next heir had become what is called matter of right.

Bracton gives what is probably the true etymology of the word. "Relevia," says he, are so called, "quia hereditas quæ jacens fuit per antecessoris decessum *relevatur* in manus heredum, et propter factam relevationem."

RELIEF [ALTO-RILIEVO.]

RELIGION is a Latin word which, according to the common derivation of it (from *religare*), means a principle which acts as a *restraint* on the conduct of man. In its more general sense it is used as an abstract term to denote our ideas of the existence and character of a Divine Being, to whose power men are more or less subject. Thus we speak of *a sense of religion* and *the duties of religion*, and we call a man who regards such subjects as matters of great importance *a religious person*. But as different views have prevailed of the nature of the deity and the relation in which man stands to him, various systems of religious belief have sprung up, and each of these systems is called *a religion*. Thus we speak of the Greek, Hindu, Jewish, Christian, and Mohammedan religions. The word is also popularly used to express the attention of individuals to the doctrines and duties of the particular religion which they may have embraced. In this sense it is synonymous with *piety*.

The subjects with which religion has to do are God and man considered in the relation in which they stand to each other. It consequently includes all the philosophical questions which can throw light upon that relation; for example, those which respect the nature of the deity, the notions of infinite space and infinite duration, the existence and offices of spiritual beings, the origin and destiny of the human race and of the world they inhabit, the immateriality and immortality of the human soul; and also all the practical questions which arise out of that relation, such as the duties which men owe to God and to each other, and the consequences which God may have appointed to follow different courses of action. All impressions, notions, and belief upon these subjects, whether formed into a system or not, constitute what we call *religion*, as distinguished from *theology*, which is the science by which these ideas are reduced to a systematic form, their laws investigated, and their origin and results traced out. [THEOLOGY.]

The sources from which our notions of religion are derived are either the so-called laws of nature and the constitution of the human mind, or direct information given to us upon the subject by the deity himself, whether such information be embodied in any lasting form, or handed down from one generation to another by oral tradition. Religion derived from the two former sources is called *natural religion;* from the last, *revealed religion.* [REVELATION.]

The fundamental principle upon which all religion rests is the notion of the existence of a Being whose power over us is absolute, whose nature is perfect in excellence, to whom we owe certain duties, and from whom we have much to hope and fear. The existence of such a Being is proved by the evidences which the objects of nature present of perfect design, of fixed order, of power sufficient to accomplish everything which we can conceive that does not involve a contradiction, and which we therefore conclude to be infinite, and of benevolent provision for the wants of living creatures. Apart from all such evidence, the belief in the divine existence seems to be strongly impressed on the human mind, so strongly indeed, that it is a matter of great doubt whether even professed atheists have been really such. Lastly, this truth may be the subject of revelation; for revelation does not, as may at first sight seem, imply as a fact *previously* known the existence of the Being from whom it comes. To the first recipients of the revelation the very fact of their finding themselves possessed of the knowledge of truths beyond the range of human experience would be a sufficient proof of the existence of a superior Being, from whom they had, in whatever way, obtained such knowledge; and if, in making known the revelation to the world, these persons should display a command over the laws of nature beyond the compass of human power, or an acquaintance with future events beyond the reach of human knowledge, these miracles and prophecies would prove the existence of a superior Being, from whom they had received the power to perform the one and the foreknowledge implied in the other. Thus the revelation itself furnishes a proof of the existence of the before unknown revealer. We do not inquire whether the divine existence is really proved in either or all of these different ways, because the object of this article is to explain the nature of religion, not to establish its truth.

The belief in a God leads at once to the practice of worshipping him, on the very same principle on which all dependants honour and look up to those in whose power they are placed.

The existence of a God once proved, the next question is, In what relation do we stand to him? Are any laws laid down for our conduct? Are we responsible to him for keeping or breaking those laws? Are any rewards and punishments appointed for obedience and disobedience?

To these questions it does not appear that natural religion can give a perfectly satisfactory answer, though no one can read Bishop Butler's admirable work, 'The Analogy of Religion, Natural and Revealed, to the Constitution and Course of Nature,' without being astonished at the amount of information on these subjects which it is there shown that the contemplation of natural phenomena reveals. It seems also that a general undefined notion of responsibility is associated in nearly all human minds with the idea of divine existence, at least a sense of responsibility sufficient to excite pleasure when we do what we believe to be good, and remorse when we do what we believe to be evil. Again, the connection which we find generally existing between vice and misery on the one hand, and virtue and happiness on the other, impresses upon us the idea that there does exist such a thing as retributive justice. But at this point we encounter the great difficulty of natural religion. Though the general law according to which the affairs of the world appear to be governed is, that virtue is followed by happiness and vice by misery; and though a full knowledge of the circumstances of every case which appears an exception to that law might show us that more real happiness is enjoyed by a virtuous sufferer than by a prosperous sinner, yet it cannot be denied that daily experience furnishes us with exceptions to this law, numerous enough to throw great doubt upon its reality, if the period of human existence ends with the present life. Accordingly we find the doctrine of a future state forming a part of all religious systems, and generally connected with some notion of rewards and punishments.

Now, if there be a supreme moral governor who rules the world by fixed laws, who has appointed rewards and punishments as the recompense for obedience and disobedience, and who has constituted man so that he shall exist in a future state to receive that recompense, the question is naturally suggested whether there be any means by which the consequences of disobedience may be averted. Justice must be an attribute of the ruler of the universe, and natural religion affords us sufficient proofs of his goodness to justify us in believing that he is also willing to show mercy. The question that remains to be answered is, how his mercy can be shown without injury to his justice; and the importance of this question is enhanced by the consideration that the great majority of mankind (experience would justify us, apart from the Christian doctrine of universal depravity, in saying all mankind) need the divine forgiveness for at least some actions of their lives. It is the highest province of religion to furnish an answer to this question; and here natural religion entirely fails us, for if left to it, the utmost we could do would be to rest in the exercise of an humble faith that some provision has been made by God for the just forgiveness of our sins, though the nature of that provision be unknown to us. The matter belongs to revealed religion, and accordingly we find in nearly every religion professing to have a divine origin, and in many others, the doctrine of an atonement; that is, of a satisfaction for sin, in virtue of which the actual transgressor may be released from the consequences of his guilt.

These, then, are the elements which seem to be contained in any religion suited to the wants of man; that there exists a supreme Being who possesses absolute power over man and the material universe, and all creatures therein, and who is to be worshipped by all his rational creatures; that he has laid down laws for our conduct, by our obedience or disobedience to which we subject ourselves to a recompense of reward or punishment, which recompense is awarded partially in the present life, but more completely in a future state, in which we are so constituted as to exist after death; that a provision has been made on behalf of those who feel that their conduct has subjected them to the divine displeasure, by availing themselves of which they may escape the consequences of their guilt without detriment to the equity of the divine government; and lastly, that there are certain practical rules of conduct by which the intercourse of men with each other ought to be governed, and by an attention to which the stability of the social system may to a great extent be ensured. And all these elements of religion are susceptible of proof, either from nature, or from human experience, or from revelation.

RELIQUARY, a case or repository for relics. The term is usually confined to the smaller relic-cases, those of large dimensions, whether fixed or moveable, being more commonly designated *shrines*. When the veneration of relics had become universal in the mediæval church, the practice of enclosing the relic in its own special case, so as to preserve it alike from danger of loss and from contact with less sacred objects, was generally adopted; and these cases, often gifts to the churches, were usually of the finest workmanship of the period, and sometimes of very costly materials. Reliquaries are among the most prized remains of mediæval art-workmanship now preserved in the ecclesiastical treasuries of the continent and in public museums. They vary of course widely in pecuniary and artistic value, and also in size and form. Those of earliest date, Byzantine in character, are frequently of copper almost wholly enamelled; and a common form, when not a mere casket or coffin, is that of a chapel or basilica, having on the sides and ends figures of Christ and the apostles, or the legend of the saint whose relics they enclosed. Later, the church form is more developed, the sides and gable-ends having, especially in French and German examples, columns, arches, crockets, pinnacles, and even towers. Those of the 13th and 14th centuries are often exquisite specimens of the art of the period. They are commonly of metal—latten, silver-gilt, or gold—with figures in relief, and enamels introduced with great taste and admirably executed. Some are of wood or ivory, beautifully carved. Sometimes they assume the form of the relic itself—as a head, heart, hand, or foot, where they were made to contain a portion of one of those members. The large reliquaries, or *shrines*, were of stone or bronze, and, where regarded as of special sanctity, were overlaid with the accumulated offerings of devotees. Thus the shrine of the Three Kings at Cologne was ornamented with jewels said to be of the value of nearly a quarter of a million. The shrine of Thomas à Becket, at Canterbury, was of almost inconceivable value. Those were, however, the real or supposed tombs of the saints, and though sometimes spoken of as reliquaries, are, as we said, more properly called shrines. Of reliquaries proper some few examples remain in our churches, as at Brixworth, near Northampton; Yaxley, near Peterborough, &c. Several good examples of enamel, metal, and carved ivory reliquaries are in the South Kensington Museum.

REMAINDER. An estate in remainder is defined by Coke to be "a remnant of an estate in lands or tenements, expectant on a particular estate, created together with the same at one time." According to this definition, it must be an estate in lands or tenements, including incorporeal hereditaments, as rents and tithes; and it is an estate which at the time of its creation is not an estate in possession, but an estate the enjoyment of which is deferred. The estate in remainder may exist in lands or hereditaments held for an estate of inheritance or for life. It must be created at the same time with the preceding estate, and by the same instrument; but a will and a codicil are for this purpose the same instrument. A remainder may be limited by appointment, which is an execution of a power created by the instrument that creates the particular estate; for the instrument of appointment is legally considered as a part of the original instrument. A remainder may also be created either by deed or by will; and either according to the rules of the common law, or by the operation of the Statute of Uses, which is now the more usual means.

If a man seised in fee simple grants lands to A for years or for life, and then to B and his heirs, B has the remainder in fee, which is a present interest or estate, and he has consequently a present right to the enjoyment of the lands upon the determination of A's estate; or, in other words, he has a vested estate, which is called a vested remainder. A reversion differs from a remainder in several respects. He who grants an estate or estates out of his own estate, retains as his reversion whatever he does not grant; and upon the determination of the estate or estates which he has granted, the land reverts to him. There may be several remainders and a reversion expectant on them. If A, tenant in fee simple, limits his estate to B for years, with remainder to C for life, with remainder to D in tail, this limitation does not exhaust the estate in fee simple. By the limitation B becomes tenant in possession for years, C has a vested remainder for life, D a vested remainder in tail, and A has the reversion in fee. If the limitation by A exhaust the whole estate, as it would have done in the preceding instance if the limitation had been to C and his heirs, A has no estate left. It is a necessary consequence that if a man grants all his estate, he can grant nothing more; and therefore the grant of any estate after an estate in fee simple is void as a remainder. Indeed the word remainder implies that what is granted as such is either a part or the whole of something which still remains of the original estate.

The estate which precedes the estate in remainder or in reversion is called the *particular* estate, being a particula or portion of all the estate which is limited; and the particular estate may be any estate except an estate at will, and an estate in fee simple. It must therefore be either an estate for years, or for life, or in tail.

Estates for years may be granted to commence at a future time; but by the rules of the common law, no estate of freehold can be created to commence at a future time. If therefore such an estate of freehold is granted, there must be created at the same time an estate for years, which shall continue till the time fixed for the enjoyment of the estate of freehold.

A remainder cannot be granted so as not to take effect immediately on the determination of the particular estate. If there is any interval left between the particular estate and the remainder in their creation, the remainder is absolutely void. A grant of an estate to A, and one day after the determination thereof to B, is a void remainder.

Estates in remainder are either vested or contingent. The remainder may vest at the time of the limitation, or it may vest afterwards: in either case the remainder-man acquires an estate in the land, to the enjoyment of which he is entitled upon the determination of the preceding estate. But it may happen that a vested remainder may never become an estate in possession.

A vested remainder is an estate which, by the terms of the original limitation or conveyance, is limited or conveyed unconditionally. If a remainder is not vested, it is contingent.

A contingent remainder is defined by Fearne to be "a remainder limited so as to depend on an event or condition which may never happen or be performed, or which may not happen or be performed till after the determination of the preceding estate." Accordingly it is the limitation of the remainder which is conditional, and there is no remainder limited or given until the condition happens or is performed. The uncertainty of the remainder becoming an estate in possession is no part of the notion of a contingent remainder; for this kind of uncertainty may exist, as already observed, in the case of vested remainders.

Fearne has made four classes of contingent remainders, to some one of which he considers that all kinds of contingent remainders may be reduced, but he adds that "several cases which fall literally under one or other of the two last of those four descriptions, are nevertheless ranked among vested estates."

The first class is, "where the remainder depends entirely on a contingent determination of the preceding estate itself;" or, as it may be explained, where a remainder is limited to take effect only on the happening of a specified contingent event which is to determine the preceding estate, and is not to take effect if the preceding estate determines in any other way. An example usually given is the following: A makes a feoffment to the use of B till C returns from Rome, and after C's return, then to D in fee. In this case B has an estate which will determine either upon C's return from Rome or by his own death; but the remainder is limited to D only upon the happening of a specified event which may never happen; and if B's estate determine by his death, or by forfeiture, which is possible, no estate is limited to D. There is then no limitation to D, except conditionally, and his estate is therefore contingent.

The second class is, "where some uncertain event, unconnected with and collateral to the determination of the preceding estate, is by the nature of the limitation to precede the remainder." This class is easily distinguished from the first, by the circumstance that the uncertain event upon which the remainder is limited, is entirely independent of the manner in which the preceding estate may or must determine. The following is an example: If a grant is made to A for life, remainder to B for life, and if B die before A, remainder to C for life, the uncertain event of B's dying before A is quite independent of the determination of A's estate, but the limitation of C's estate depends on this uncertain event happening.

In both these classes of remainders, the event on which the remainder is to take effect is absolutely uncertain; in the two following classes, the events on which the remainders are limited are events which certainly must happen, and the contingency arises from the uncertainty of the time when they will happen.

The third class is, "where a remainder is limited to take effect upon an event, which, though it certainly must happen some time or other, yet may not happen till after the determination of the particular estate." The following is an example: A grant is made to J. S. for life, and after the death of J. D. the lands to remain to another in fee. Though it is certain that J. D. must die, this event, upon which the limitation in fee is to take effect, may not happen till after the determination of the life estate of J. S.

The fourth class is, "where a remainder is limited to a person not ascertained, or not in being at the time when such limitation is made." The following is an example: A grant is made to A for life, remainder to the right heirs of J. S. Now as J. S. can have no heir till he is dead, and as he may not die till after the determination of the particular estate, such remainder is contingent. If an estate is limited to two persons for life, with remainder in fee to the survivor, the remainder is contingent, because it is uncertain which will be the survivor.

The numerous exceptions to the fourth class of contingent remainders are comprehended in what is called the Rule in Shelley's case, of which a complete exposition is given in Fearne's 'Essay on Contingent Remainders;' and in Preston's 'Treatise on Estates' (vol. i.). The nature of this rule may be generally stated as follows:—If lands are limited, either by deed or will, to a man for life, and after his death to his heirs or the heirs of his body, the limitation to the heirs would appear to be a contingent remainder according to the definition of the fourth class of contingent remainders, for the heirs are persons who cannot be ascertained till the death of the person to whom the estate for life is given. But it is an old rule of law that the estate so limited to the heirs or the heirs of the body takes immediate effect as an estate in the ancestor, and therefore, in the former case, A takes an estate of freehold with a vested remainder in fee. His life estate is consequently merged in his remainder in fee, and he becomes tenant in fee simple in possession. If an estate for life, or an estate tail, is interposed between the estate for life to the ancestor and the remainder to his heirs or the heirs of his body, still this remainder is vested in the ancestor, just in the same way as if it were limited to him and his heirs, or to him and the heirs of his body. Thus when A takes an estate for life, remainder to B for life, remainder to C in tail, remainder to the right heirs of A, this ultimate remainder is a vested remainder in fee in A, and, after his death and the determination of the intermediate estates, his heir will take by descent. But cases within this rule are not so properly exceptions, as cases which by the operation of the rule are excluded from the fourth class of contingent remainders.

There is another exception to the fourth class, which is allowed in devises, where it can be clearly inferred from the particular expressions in the will, that a limitation to the heir special of a person then living is intended as a designation of a particular person. In such case the remainder will vest; for the conclusion is, not that the testator intended to limit the estate by way of contingent remainder to such person as should be ascertained to be heir by the death of his ancestor, but that he intended by the word "heir," accompanied with the other expressions in the will, to designate a particular person.

A contingent remainder may intervene between the particular estate and other limitations over, and yet the subsequent limitations may be vested, if made to a person *in esse,* provided the contingent limitation is not in fee simple. The contingent remainder itself may also vest, and then become an estate interposed between the particular estate and the subsequent vested limitations, if the contingency happens during the existence of the particular estate. If in the same conveyance an estate is limited to A for life, followed by a contingent remainder and a subsequent limitation to A and his heirs, or A and the heirs of his body, this last limitation, though executed under the rule in Shelley's case, is still so executed as to allow the contingent remainder to interpose as a vested estate when the contingency happens. A subsequent contingent limitation may vest before a preceding one, but it follows from what has been said that the preceding one is still capable of vesting.

Lands may be so limited as to be subject to a general power of appointment. In such cases, the general power of appointment will not prevent the estates limited in default of appointment from vesting; though the due exercise of the power will divest them.

A contingent remainder may be limited generally upon any event, except in such cases as the following:—the contingent event being illegal; the remote possibility of the contingent event; and the condition enuring to defeat the preceding estate. These subjects are fully discussed by Fearne (c. 2).

It will be collected from what has been said that a contingent remainder of freehold must be preceded by a vested estate of freehold; for if there is no precedent vested estate of freehold, and the freehold remainder is contingent, the freehold either remains in the grantor, and therefore is not transferred to any one else, or it is transferred in some remainder which is limited after the contingent remainder, and which, being therefore vested in possession, precludes all possibility of the vesting of the contingent estate, which by the terms of the limitation must precede it. This rule as to the necessity of a vested freehold estate to support a contingent remainder, applies both to limitations of uses and of estates limited at common law.

It will also appear from the definitions of contingent remainders that they must vest, that is, the conditions on which they are limited must be fulfilled, during the continuance of the particular estate or immediately on its determination. One of the cases in which such remainders were formerly liable to fail under the fourth class of contingent remainders, was in the case of such limitations as to A for life, and to his first and other sons in tail. Originally a posthumous son could not take, but such child is now for this and several other purposes considered as a person *in esse* during the period of pregnancy. When a contingent remainder is limited to several in a conveyance to uses or by a devise, such remainder will vest in the first person in whom it can vest, but it will divest in due proportions in favour of other persons who are included in the limitations, and who become capable of taking before the determination of the particular estate; and such persons may take as joint tenants, though their estates vest at different times.

Formerly, any determination of the particular estate before a legal remainder vested, destroyed the contingent remainder. The contingent remainder might fail not only through the contingency not happening till after the expiration of the particular estate, but through its destruction by the surrender of the tenant for life, or by the forfeiture of his estate during the existence of the contingency. The intermediate contingent remainder was also destroyed if the particular estate and the next vested estate of freehold became united by the conveyance or act of the parties, so that the particular estate was merged. Now, however, it has been enacted by the statute 8 & 9 Vict. c. 106, that contingent remainders shall be capable of taking effect, notwithstanding the determination by *forfeiture, surrender,* or *merger* of any preceding estate of freehold.

A contingent remainder of an estate of inheritance is descendible to the heirs of an ascertained person to whom it is limited, if such person should die before the contingency happens, and it will vest if the same should happen during the continuance of the particular estate. Contingent remainders were once not considered devisable, but it was afterwards determined that they were devisable whenever they were descendible to the heirs of the persons to whom they were limited; and under the statute 1 Vict. c. 26, they are devisable in common with all contingent, executory, or other future interests in any real or personal estate.

Though a fee cannot be limited after a fee as a remainder, two or more contingent fees may be limited in the alternative, so that one only shall take effect.

Interests in chattels real and personal are susceptible of limitations over after the limitation of some partial interest in them; but from the nature of those interests they are incapable of such extensive modifications as freehold interests in land, and they cannot be operated upon by the Statute of Uses. Originally a bequest of a term of years to a man for his life was an absolute gift of the whole term, and the donee might dispose of the whole interest as he pleased; but at present a bequest of such term to A for life, and after his death to B, is a bequest of the whole term to A, subject to an executory bequest to B, to take effect if A dies before the expiration of the term. It is not a particular estate to A for life and a remainder to B. Any disposition of a chattel, which in the case of lands would make an estate tail, gives the whole interest. Thus if the second bequest of the term of years were to B and the heirs of his body, B would take the whole interest.

An executory devise is such a limitation of a future estate in lands, and an executory bequest is such a limitation of a future interest in chattels, as are allowed in the case of a will, though not in conveyances at common law. Accordingly a fee may be limited after a fee in a will or by way of use upon contingencies which may happen within certain limits of time; and such limitations take effect as executory devises or springing or shifting uses. But when future estates are so limited by devise as to be comprehended within the rules which apply to contingent remainders, they will be considered as such, and not as executory devises.

The subject of contingent remainders is fully discussed in the elaborate Essay of Fearne on 'Contingent Remainders and Executory Devises;' see also Hayes, 'On Conveyancing,' Appendix.

REMEMBRANCERS (*rememoratores*), formerly called clerks of the remembrance (37 Edw. III. c. 4), are officers of whom, until recently, there were three in the exchequer, called respectively the king's remembrancer, the lord treasurer's remembrancer, and the remembrancer of first fruits; their duty being to put the lord treasurer and the barons of the exchequer, who are the judges of that court, in remembrance of such things as are to be called on and done for the king's benefit.

I. The office of the queen's remembrancer has relation to the proceedings of the court of exchequer in the exercise of its original jurisdiction as a court of revenue, and of its incidental jurisdiction as a court of equity, founded upon the fiction that the party seeking for relief upon matters of equity is a debtor and an accountant to the crown, who by reason of the withholding of that to which he is equitably entitled, is the less able (*quo minus sufficiens existit*) to pay his debts to the crown. On the revenue side, the queen's remembrancer enters all the recognizances taken before the barons for any of the queen's debts, for appearances, &c., and he takes all bonds for such debts, and for the due execution of offices, and makes out process for breach of them; he also writes process against the collectors of customs, excise, and other public payments, for their accounts. Informations for intrusion into the queen's lands, and information for debts due to the crown, and on penal statutes, are entered and sued in his office; and he makes the bills of composition on penal laws. Indentures and other evidences which relate to the passing of any lands to or from the crown are delivered into his office; and commissions of nisi prius, by her majesty's warrant, on trial of any matters within his office, commissions to find debts due to the crown, and writs of extent awarded in pursuance of 33 Hen. VIII. c. 39, are issued and prosecuted in this office; also general process for the recovery of arrears of taxes and other debts due to the crown, which issue twice a year. All differences as to irregularities in proceedings are determined by the queen's remembrancer, with power to give costs against the party in fault, but subject to an appeal to the court. (5 Rich. II. st. 1, cc. 15, 16; 13 & 14 Car. II. c. 21.) He is bound by a rule of court, 3 Jac. II., to attend the court during its sittings, to answer inquiries respecting the course of proceedings, and to enter the rules and orders of the court of exchequer relating to its fiscal or its equitable jurisdiction, and he executes the duties formerly performed by the lord treasurer's remembrancer, now abolished by 3 & 4 Will. IV. c. 99. This office is now held by one of the masters. (22 & 23 Vict. c. 21.)

II. The lord treasurer's remembrancer's office was the office principally concerned in matters relating to the landed and casual revenue of the crown. When the king's title was found by an inquest of office, it became the duty of the officer with whom the writ and inquisition remained, to send a transcript into the office, in order to being put in charge for the service of the crown; he issued process for debts to the king, and against sheriffs, escheators, &c., and others who did not account. He took the accounts of all sheriffs, and made the record, whereby it appeared whether sheriffs and other accountants paid their proffers, that is, the balance appearing upon their accounts, due at Easter and Michaelmas, and he made another record showing whether sheriffs and other accountants kept their days prefixed. There were also brought into his office all the accounts of customers, comptrollers, and accountants, which were to be entered on record.

All estreats of fines, issues, and amerciaments, set or imposed in any of the courts at Westminster, or at the assizes or sessions, were certified into his office, and by him delivered to the clerk of the estreats, to make out process on them; and he might issue process for discovery of tenures and all revenue due to the crown by reason thereof, &c. As soon as the estreats came into this office, the parties interested might appear and deny the king's right, upon which the pleadings between the crown and the claimant were carried on in this office according to the course of the common law; and the right was either determined by the court upon demurrer or by verdict of a jury. The pleadings and judgments were entered on rolls called the 'Memoranda' of each year. Those of the reign of Edw. I. were published by Serjeant Maynard, in the first volume of his edition of the Year-Books.

Parties may apply in a summary manner for the indulgence of the court of exchequer, which is empowered by privy seal, at the commencement of every reign, to compound or discharge any fines, issues, amerciaments, or recognizances, according to the circumstances of each case; and until the statute of 3 & 4 Will. IV. c. 99, such applications passed through this office. By that statute, the office of the lord treasurer's remembrancer was, with the offices connected therewith, abolished. Part of the duties of this office had been previously transferred to other offices, part ceased by the Act, and the remainder are performed by the queen's remembrancer.

III. The remembrancer of the first fruits office receives the bishops' returns of institutions, takes all compositions and bonds for payment of first fruits and tenths, and makes process against all such persons as do not pay the same.

IV. Remembrancer of the City of London. The duties of this officer are those of agent for the corporation in parliament, and at the council and treasury boards. He gives a daily attendance at the houses of parliament during every session, to examine all bills and proceedings of the houses of lords and commons, and to report on such as may be likely to affect the interest or privileges of the city. For this purpose, the officers of both houses of parliament give him facilities of admission and attendance; and, for the purpose of identification by them, he sometimes wears a medal with the arms of the city. His duty is further to take the necessary steps to procure the presentation of all addresses and resolutions of the corporation to the sovereign and all the branches of the royal family: to make copies of the addresses and deliver the same, and to attend the sheriffs, when the appointment is made to receive the address or resolution, and the corporation, when the same is presented: to engross all petitions of the corporation to be presented to either house of parliament: to make and deliver copies, and to attend when the petitions are presented. If the petition be to the house of lords, the remembrancer, with the sheriffs, waits on some peer of parliament, and requests him to present it. He has to give the city members and the sheriffs notice when petitions are to be presented to the house of commons: to make applications for obtaining, and, when received, to distribute, the city imposts for duties on wine, an allowance made by the lords of the treasury, the origin of which is not known. The earliest entry of its being made is about the year 1680. The sum allowed is 100*l.* 16*s.*, which is distributed in different proportions amongst the lord mayor, aldermen, recorder, sheriffs, common serjeant, chamberlain, town-clerk, remembrancer, and sword-bearer. ('Second Report on Municipal Corporations of England and Wales,' 1837.)

REMONSTRANTS. [PELAGIUS, in BIOG. DIV.]

RENAISSANCE (Architecture). The term Renaissance indicates the period of the *Revival*, when the classical began to be re-introduced after the mediæval styles. The term is used alike in architecture, sculpture, and ornamental art: our attention in the present article will be confined to architecture.

The Renaissance had its origin in Italy, where at best Gothic architecture secured but a precarious hold. As soon as the passion for the old Roman literature sprang up, there arose also a desire for the study of classic art, to be followed before long by the attempt to imitate it. Traces of the imitation of Roman architectural forms are observable of as early a date as the middle of the 14th century. But the true Renaissance dates from the time of Brunelleschi (or the early part of the 15th century), in whose hands it assumed character and consistency. Its full development, however, belongs to the century following. [ITALIAN ARCHITECTURE.]

Although all were derived from that of Italy, each country had its peculiar Renaissance, described accordingly as French, German, English Renaissance [ELIZABETHAN ARCHITECTURE], preserving a general family likeness, but each exhibiting traits exclusively its own. The Renaissance in general is often spoken of as if it were nothing more than a direct but unskilful imitation of the antique, previously to the orders being so well understood as they were afterwards when studied through the text of Vitruvius, and reduced to a methodical system of "bookish rules," by Palladio and Vignola. But in the first place it was founded only upon the *Roman* antique, and in the next, not upon the temple style of the Romans, but their triumphal arches, baths, and other edifices. It was not either the portico, or the continuous colonnade, where columniation displays itself in all its purity, that was taken as a model, but rather such structures as the Colosseum, where several small orders—that is, small in proportion to the general mass—are introduced for little more than decoration to it. And in the Renaissance and Cinque-cento (or 1500—as we should say, 16th century) styles, entire orders are used only as embellishment, and avowedly so. Where columns are employed for actual support, as in open loggie, it is only in combination with arches springing from them, the columns performing the office of piers to the arches. A great deal of Italian Renaissance is, however, *astylar*, with either a full entablature, or a cornicione crowning and proportioned to the entire mass. This large and simple mode of treatment was greatly affected by the Florentine and Roman architects of the period of the revival, and contrasts very strikingly with the Transalpine Renaissance in France and other countries, which is characterised by multiplicity of parts, and numerous divisions and breaks. It contrasts also with the contemporary practice of the Italian architects themselves when they employed the orders, in doing which they made their compositions *microstylar*, applying a separate small order to each floor or horizontal division of a façade, above the ground floor; and they further reduced the height of the columns by giving a considerable proportion of each order to high pedestals beneath the columns.

In Transalpine Renaissance such application of the orders was greatly exaggerated, they being employed for the ground floor as well as the others, and the spaces between the columns being filled in, either entirely or nearly so, with large windows, so that the columns or pilasters between them show only as accessories to the windows themselves, and as narrow piers between them. Fenestration completely predominates, both as to the quantity of surface the openings occupy, and the architectural character occasioned by it. One of the earliest importations of the Renaissance into this country, Longleat House, Wilts, erected by John of Padua, 1567, is an instance of such mode of composition, and shows how greatly the borrowed style was transformed in its general physiognomy, even when treated faithfully with regard to details.

One deviation from Italian practice was the frequent employment of coupled columns or pilasters, which was in some cases (as at Wollaton Hall, see ELIZABETHAN ARCHITECTURE) caused by the necessity for wider piers between the windows, at the same time that the intercolumns were completely occupied by the windows, which last, it should be observed, retained their Tudor or English character, being very spacious and divided by mullions and transoms.

In much of the Italian Renaissance, especially in that for which purity and correctness were affected, the character of the detail is somewhat dry and meagre, and there is very little of ornamentation, even the entablatures to Corinthian columns consisting of only plain mouldings. Florid Renaissance, as it may for distinction's sake be called—seems, on the contrary, to have been most in favour both in France and in our country, probably in consequence of the taste for luxuriant enrichment which had been indulged during that period of Gothic architecture which the new style was beginning to replace. Besides which, it was out of Italy adopted as an exotic fashion, owing to which and to its being at first employed for palatial and sumptuous structures, it was displayed in all its luxuriance. This florid species of the style and period is marked by a profusion of enrichment and carvings in mouldings, panels, and friezes, by arabesque foliage and medallions, with which surfaces of considerable extent are oftentimes covered. The carvings consist of grotesque animals, foliage, &c., extended into scroll-work, interlaced in an entirely capricious manner, of the kind known as ARABESQUE. In Italian Renaissance the same kind of sculpture occurs, but purer in design, more graceful in style, and more refined in execution. Figures of Amorini, with medallions, on which are portraits, armorial bearings, &c., are common, especially in interiors. Even the shafts of columns are frequently damasked or broidered, if not for their entire height, for a considerable portion of it, and generally the lower ones, with foliage and other chasing; besides which they are further enriched by one or more bands embossed in similar manner. The faces both of pilasters and pedestals are also highly decorated by being panelled, and filled up with arabesque work or other sculptures. Niches, too, are frequent features in composition, and within, their heads are generally carved to resemble a shell; as are also devices, mottos, and other inscriptions. This profusion of minute ornament is eminently characteristic of the Renaissance taste in building, furniture, and decoration generally; and though it was then carried to excess, and the combinations themselves were often very uncouth, grotesque, and what is understood by the term quaint (oddly picturesque, but not beautiful), much of the ornament is, taken separately, marked by elegance as well as fancy. Some examples from Italian interiors, of characteristic design and admirably carved, may be seen in the South Kensington Museum.

French Renaissance dates from the reign of Louis XII., who employed Italian artists, and among others the architect Giocondo [GIOCONDO, in BIOG. DIV.], who erected for Cardinal d'Amboise, the minister of that monarch, the celebrated Château Gaillon. Though that edifice—at least what remained of it,—was taken down some years ago, it is known from the representations of it, and also from such fragments of it as have been preserved by being reconstructed at the Ecole des Beaux-Arts, Paris, to have been an exceedingly sumptuous pile. The buildings towards the court were almost entirely incrusted over with panelled pilasters, arabesques, medallions, and other sculpture. The Château de Blois, the birth-place of Louis XII., and restored and decorated by him, was another distinguished work of that period, and probably one of those on which Giocondo was employed. In the reign of Francis I., the palaces erected by that sumptuous prince and his nobles attested the magnificence if not the refinement of that age. As a retreat for himself in the immediate vicinity of his capital, Francis built (about 1530) the Château de Madrid in the Bois de Boulogne, whose façades were decorated with coloured enamelled tiles, constituting a species of polychromic decoration. Of that building nothing now remains, it having been taken down at the end of the last century; but another architectural specimen of the same period, the house or casino of Francis I., erected at Moret, near Fontainebleau, has been preserved by being removed to Paris, where it was re-erected in its primitive state, in the Bois de Boulogne, by the architect Biet, in 1823. Of this interesting monument of the Renaissance, which has also some polychromic Robbia-ware decoration, plans, elevations, and sections, are given in Normand's Paris Moderne, but being only in outline, a great deal of the effect is lost in them. The palace of Fontainebleau itself, in its interior at least, records the magnificence of Francis, his taste for splendour, and his liberal encouragement of arts. The Tuileries, as built for Catherine di Medicis, by Philibert Delorme and Bullant, is another great example of French Renaissance when at its best, which has undergone such alterations as to be no longer recognisable. By French writers generally, the style is considered to have risen to its highest point of excellence in the hands of Philibert Delorme [DELORME, in BIOG. DIV.] in the reigns of Henry II. and Francis II.: but it perhaps appears to more advantage in the edifices built in the reign of Francis I.

In Germany, the castle or rather palace of Heidelberg would, if completed, have been a most gorgeous pile in the Renaissance style, as it showed itself in that country; and though now a ruin, the principal portion of the exterior is in sufficiently good preservation to admit of faithful restoration, in a series of architectural engravings. German Renaissance was even more exuberant, not to say extravagant, alike in constructive character and decorative details, than even the French.

The Renaissance edifices of Spain are many of them interesting and striking specimens of the kind. Among them may be mentioned, as deserving of particular notice for the elegant taste it displays, the upper gallery of the cloister of the Convent of Huerta; also the Town Halls of Zaragossa and of Seville; and the Alcaza at Toledo.

RENT, in Political Economy, is defined by Mr. Ricardo to be "that portion of the produce of the earth which is paid to the landlord for the use of the indestructible powers of the soil. It is often, however (he remarks), confounded with the interest and profit of capital, and in popular language the term is applied to whatever is annually paid by a farmer to his landlord." Mr. Malthus ('Prin. of Pol. Econ.') defines rent to be "that portion of the value of the whole produce which remains to the owner of the land, after all the outgoings belonging to its cultivation, of whatever kind, have been paid, including the profits of the capital employed, estimated according to the usual and ordinary rate of the profits of agricultural capital at the time being."

As most modern economists have adopted the main principles of the Ricardo theory, we here give an outline of it, in the words of Mr. Ricardo:—"If all land had the same properties, if it were boundless in quantity and uniform in quality, no charge could be made for its use, unless where it possessed peculiar advantages of situation. It is then because land is of different qualities with respect to its productive powers, and because, in the progress of population, land of an inferior quality, or less advantageously situated, is called into cultivation, that rent is ever paid for the use of it. When, in the progress of society, land of the second degree of fertility is taken into cultivation, rent immediately commences on that of the first quality, and the amount of that rent will depend on the difference in the quality of these two portions of land. . . . With every step in the progress of population which shall oblige a country to have recourse to land of a worse quality to enable it to raise its supply of food, rent on all the more fertile land will rise. . . . If good land existed in a quantity much more abundant than the production of food for an increasing population required, or if capital could be indefinitely employed without a diminished return on the old land, there could be no rise of rent; for rent invariably proceeds from the employment of an additional quantity of labour with a proportionally less return."

Rent, according to the definition which has been given, consists of a surplus which remains after the capital expended in production has been replaced with ordinary profits. This surplus, which constitutes rent, arises, as Mr. Ricardo asserts, from, and is in proportion to, the necessity for resorting to inferior soils or employing capital on the old soil with small returns. To use the words of Mr. Mill, his friend and disciple—"Rent is the difference between the return made to the more productive portions and that which is made to the least productive portion of capital employed upon the land." In a country containing, as every country does contain, land of various degrees of fertility, rent therefore will not be paid until the demands of an increasing population have rendered it necessary to have recourse to the inferior soils. "Thus (continues Ricardo), suppose land, Nos. 1

2, 3, to yield, with an equal employment of capital and labour, a net produce of 100, 90, and 80 quarters of corn. In a new country, where there is an abundance of fertile land compared with the population, and where therefore it is only necessary to cultivate No. 1, the whole net produce will belong to the cultivator, and will be the profits of the stock which he advances. As soon as population had so far increased as to make it necessary to cultivate No. 2, from which 90 quarters only can be obtained after supporting the labourers, rent would commence on No. 1; for either there must be two rates of profit on agriculture, or ten quarters or the value of ten quarters must be withdrawn from the produce of No. 1 for some other purpose. Whether the proprietor of the land or any other person cultivated No. 1, these ten quarters would equally constitute rent; for the cultivator of No. 2 would get the same result with his capital, whether he cultivated No. 1, paying ten quarters for rent, or continued to cultivate No. 2, paying no rent. In the same manner it might be shown, that when No. 3 is brought into cultivation, the rent of No. 2 must be ten quarters, or the value of ten quarters, whilst the rent of No. 1 would rise to twenty quarters. . . It often and indeed commonly happens that before Nos. 2 and 3, or the inferior lands, are cultivated, capital can be employed more productively on those lands which are already in cultivation. . . In such case, capital will be preferably employed on the old land, and will equally create a rent; for rent is always the difference between the produce obtained by the employment of two equal quantities of capital and labour. If with a capital of 1000*l.* a tenant obtain 100 quarters of wheat from his land, and by the employment of a second capital of 1000*l.* he obtain a further return of 85, his landlord would have the power, at the expiration of his lease, of obliging him to pay 15 quarters, or an equivalent value for additional rent; for there cannot be two rates of profit. If he is satisfied with a diminution of 15 quarters in the return for his second 1000*l.*, it is because no employment more profitable can be found for it. . . In this case, as well as in the other, the capital last employed pays no rent. For the greater productive powers of the first 1000*l.*, 15 quarters is paid for rent; for the employment of the second 1000*l.* no rent whatever is paid. If a third 1000*l.* be employed on the same land, with a return of 75 quarters, rent will then be paid for the second 1000*l.*, and will be equal to the difference between the produce of these two, or 10 quarters; and at the same time the rent of the first 1000*l.* will rise from 15 to 25 quarters, whilst the last 1000*l.* will pay no rent whatever." (Ricardo's 'Prin. of Pol. Econ.,' 3rd edit.) Perhaps however the clearest definition of this theory of rent is that given by Mr. Mill, in his 'Elements of Pol. Econ.,' to the last edition of which work we refer for a more complete examination of the subject.

RENT (in Law Latin, *redditus*, "a return") is a right to the periodical receipt of money or something valuable in respect of lands or tenements held by him from whom the rent is due. There are three kinds of rent—rent-service, rent-charge, and rent-seck.

There is rent-service when a tenant holds lands of his lord by fealty and certain rent, or by homage, fealty, and certain rent, or by other services and certain rent. Rent-service therefore implies tenure, and it may be due to the lord of the manor of which the lands are held, or to some other chief (that is, immediate) lord of the fee, or to the reversioner. The right of distress is an incident to rent-service in arrear, so long as it is due to the same person to whom fealty is due. Before the Statute of Quia Emptores (18 Edw. I.), a person might make "a feoffment in fee simple either by deed or without deed, yielding to him and his heirs a certain rent, which was a rent-service, and for this he might have distrained of common right; and if there were no reservation of any rent, nor of any service, yet the feoffee held of the feoffor by the same service as the feoffor did hold over of his lord next paramount." (Litt., 216.) The Statute of Quia Emptores enacted that the feoffee shall hold of the chief lord by the same services by which the feoffor held, and consequently no rent can now be reserved when a man transfers to another all his estate in land. In order that rent-service may now be created, the person to whom the rent is reserved must have a reversion in the lands and tenements out of which the rent is to issue; but any reversion is sufficient. Thus a person who has a term of twenty years may grant it to another, all but one day, and this will leave him a reversion, so that a rent-service may be reserved, with its incidents of fealty and the right of distress. If he assign all his term, reserving a rent, but without a clause of distress in the assignment, he cannot distrain for the rent.

Rent-service therefore which has been created since the Statute of Quia Emptores can only be reserved to the lessor who retains a reversion, and it will belong to the person who is entitled to the reversion. If a man seised in fee simple makes a lease of lands for years, reserving rent, the rent-service is descendible to his heir with the reversion; though all rents which accrue due to the lessor before his death will belong to his personal representatives. A rent-service reserved out of chattels real will of course belong to the personal representatives of the lessor. A rent is now most commonly reserved in leases for years, but it may be reserved on any conveyance which passes or enlarges an estate; and it may be reserved in the grant of an estate in remainder or reversion, or in a grant of a lease for years to commence at a future time.

A rent service may be separated from the reversion or seignory, by the reversioner granting the rent and retaining the fealty: in this case the lands are still held of the grantor, but the rent is due to the grantee; not however as rent service, but as rent seck (*redditus siccus*), so called, "for that no distress is incident to it." (Litt., 218.) If the seignory or reversion is granted, the rent service will pass by the grant, and the grantee is entitled to receive the rent from the tenant from the time that he gives him notice of the grant, together with all rent that had accrued due since the grant, and is unpaid at the time of such notice.

Rent-service can only be reserved to the feoffor, donor, or lessor, or to their heirs, upon any feoffment, gift, or lease; and if the rent is reserved generally, without specifying the persons, it will belong to the lessor, and after his death to those who are entitled to the reversion. Rent is payable at the times mentioned in the reservation, but not till the last minute of the day on which it is payable.

When rent-service is in arrear, the common-law remedy for the recovery of it is by distress. [DISTRESS.] By 4 Geo. II. c. 28, s. 2, every landlord who by the terms of his lease has a right of re-entry in case of non-payment of rent, may, when half a year's rent is due, and there is no sufficient distress on the premises, serve a declaration in ejectment on his tenant, without any formal re-entry or previous demand of rent, and a recovery in such ejectment is final and conclusive, unless the rent and all costs are paid within six calendar months after the judgment in the action of ejectment has been executed. The action may also be stayed before trial, if the tenant will pay or tender to the lessor, or pay into court, all the rent then in arrear, together with the costs. By the common law the lessor has also an action of debt for rent against a lessee for years or at will; and by the statute of Anne (8, c. 14, s. 4) there is also the same action against a lessee for life during the continuance of his estate, which had previously been given for arrears of rent after the determination of the estate (32 Hen. VIII. c. 37). A lessor may also have an action of covenant for rent, either by force of the implication contained in such words as "yielding and paying" rent, or by force of an express covenant to pay, which is seldom omitted in any lease. If the lessee assign his interest in the term, he and his executors, so far as they have assets, are still liable under the covenants to the person entitled to the reversion. The assignee also becomes bound by such of the covenants as run with the land, and is consequently liable to an action upon them. There is also the remedy by action of assumpsit or debt for the use and occupation of land, which action lies without any express agreement for rent (see a remark on this action, 6 A. & E., p. 839).

Rent-service may be discharged in various ways. If the tenant be evicted from the lands demised to him, he is discharged from payment of the rent; and if the lessor purchase the lessee's interest, the rent is also discharged. The lessor may release a part of the rent-service, without releasing the whole.

If the person entitled to the rent-service purchases part of the interest in the land in respect of which rent is due, the rent-service is apportioned according to the value of all the land, and accordingly the tenant is discharged from payment of rent in respect of the part purchased. The person entitled to the reversion may also grant his interest in part of it, and the rent will be apportioned between him and his grantee; for the interest in the reversion is of a divisible nature, and the rent follows the reversion. If the lessee should be evicted out of part of the lands, there will also be an apportionment. Before the late alterations of the law, when the moiety of a reversion was extended on an elegit, the rent was apportioned, and the lessor consequently retained half of it. If a widow is entitled to dower of a reversion, she is also entitled to one-third of the rent reserved upon a lease for years made by her husband.

At common law, if a tenant for life died before the rent became due, which was reserved on a lease that determined by the death of the tenant for life, his personal representatives could not claim an appointment of the rent, nor could the reversioner or remainderman claim such portion as accrued due during the life of the tenant for life. But such an apportionment was given to the personal representatives by stat. 11 Geo. II. c. 19, s. 15. The Act 4 & 5 Will. IV. c. 22, extends the provisions of this Act to rents reserved on leases that determine on the death of the persons who make them, though they are not strictly tenants for life, and on leases of lands held *pur auter vie;* and by the same Act all rents-service reserved on any lease by a tenant in fee or for any life interest or under any power, and granted after the passing of this Act, and all rents-charge and other rents, annuities, &c., made payable under instruments executed, or (being a will) coming into operation after the passing of the Act, shall be apportioned, and a proportionable part thereof, from the last time of payment to the day of the death of the party interested therein, paid to the personal representatives of such party.

A rent-charge is a rent granted out of land either at common law or by the Statute of Uses, with a power of distress for the recovery of the rent. Such rents may be created by the owner of the land who retains the property of it; and they may also be reserved on the alienation of the land. These rents differ from rent service in not being connected with tenure, and the remedy by distress is therefore not an incident to rent-charges, but is created by the same instrument which creates the rent-charge. If no power of distress is given, the rent is a rent-seck. Rent-charge may be created either by deed or by will. Sometimes, by the terms of the grant, the grantee of a rent-charge is empowered to enter on the land and satisfy himself for all arrears out of the profits of the land. When a rent-charge is created under the Statute of Uses (ss. 4, 5) with a power of distress and entry upon the land in case of arrear, the person to whom the rent-charge is given obtains the legal estate in the rent-charge, with all the remedies for its recovery, as he would by a direct grant of the rent-charge; and the same instrument (lease and release) which creates the rent-charge may also make a settlement of the lands charged with the rent. In this way in a marriage settlement a rent-charge may be provided for the wife's jointure.

An estate in a rent-charge may be either in fee simple, or in fee tail, for lives or for years, according to the terms of the original limitation. A rent-charge of inheritance is real estate, and descendible to the heir; but a payment that is due belongs to the person representative. There may also be an estate in fee simple in a rent-service created before the Statute of Quia Emptores. A rent-charge in fee simple is subject to curtesy and dower; and also a rent-charge in tail. But if a rent-charge be created and granted to a man and the heirs of his body, his surviving wife will not be entitled to dower if the husband dies without issue. Until the Act 3 & 4 Will. IV. c. 106, a woman was not entitled to dower out of a rent-charge, unless her husband had the legal estate in it. A rent-charge may be limited by way of remainder; and a new rent-charge may be created to commence at a future time.

A rent-charge may be discharged in various ways. If a man who has a rent-charge out of certain lands buys any part of them, the whole rent is discharged, for it issues out of the whole of the lands; and the consequence is the same if he releases all his right in any part of the land. But a man may release part of the rent-charge without affecting the remainder; and a division or apportionment of a rent by conveying part of it to a stranger is a valid conveyance. If part of the lands which are subject to the rent-charge descend to the grantee, the rent will be apportioned according to the respective value of the two parts of the land.

A rent-seck, as already mentioned, is not, like rent-service, accompanied with a right to distrain at common law; but by the stat. 4 Geo. II. c. 28, s. 5, this distinction in respect of remedy between rent-service and rent-seck is abolished; and the Act also applies to rent-seck created prior to the statute which had been duly paid for three years out of the last twenty years. Other rents, though they belong to one of the three divisions above mentioned, are often distinguished by particular names: thus the rent due from a free-holder is called a chief rent (*redditus capitalis*); the rents of free-holders and ancient copyholders of manors are sometimes called rents of assise, being *assisi*, or ascertained, and also quit-rents (*quieti redditus*), because they are a quittance and discharge of all services.

A fee-farm rent is properly a perpetual rent-service reserved by the crown, or, before the Statute of Quia Emptores, by a subject, upon a grant in fee simple. The purchaser of fee-farm rents originally reserved to the crown, but sold under 22 Car. II. c. 6, has the same power of distress that the king had, and so may distrain on other land of the tenant not subject to the rent.

By the stat. 42 Geo. III. c. 116, in cases where the land-tax has not been redeemed in due time by the owner of the land, it may be purchased by any other person, to whom it will belong as a perpetual rent-charge (though it is called a fee-farm rent in the Act), and the purchaser will have all the remedies for rent reserved on a lease.

By the stat. 3 & 4 Will. IV. c. 27, s. 42, no arrears of rent or of interest in respect of any sum of money charged upon or payable out of land or rent, or any damages in respect of such arrears of rent or interest, shall be recovered by any distress, suit, or action, but within six years next after the same respectively shall have become due, or some acknowledgment in writing given to the person entitled thereto by the person by whom the same was payable; except where there has been a prior mortgagee or other incumbrancer in possession of any land or receipt of the profits thereof within one year next before an action or suit shall be brought by a subsequent mortgagee, &c.; and then the arrears of interest may be recovered for the whole time such prior mortgagee, &c., was in such possession or receipt.

REPEATING CIRCLE. The principle of repetition from which this circle has its name was first explained by Tobias Mayer, professor of the university of Gottingen, in 'Commentarii Societatis Regiæ Scientiarum Gottingensis,' tom. ii., p. 325, for the year 1752. Mayer found that the common surveying instruments were often inaccurate to 5′, while the quadrant, then used in all great scientific surveys, was, from its weight and price, and the trouble required for verifying and adjusting it, scarcely to be considered a portable instrument, but only fit for the observatory. The substitute which he proposed for geodesical purposes may be described briefly as follows:—Suppose a hollow tube fitting upon an axis, to which it can be clamped, when required, by a screw; the axis itself is fixed on the top of a staff. This part of the instrument is exactly similar to a common mounting for surveying compasses, &c., where greater stability is wanted than a ball and socket will give. On the top of the tube a flat bar is screwed, the plane of which is horizontal when the tube and axis are vertical; the bar and tube thus form one piece, which has the shape of a T. A second bar of the same length is placed exactly above the former. This latter bar moves easily, and without shake, on a pin concentric with the tube and axis, and thus can be placed at any angle with the fixed rule, and, as it is supposed, without at all disturbing it. Two fine dots are pricked towards the ends of each bar; the lines joining the dots in each should pass exactly through the axis of motion of the upper bar, and the dots must be equidistant from the centre. When this is so, the four dots will, in every position of the bars, be the angular points of a rectangle, and the equality of the opposite sides can be ascertained by measuring the distance with compasses. Finally, on the top of the upper bar a telescope with cross wires is fixed, the telescope being a little shorter than the bar, that it may not interfere with measurements between the dots.

The mode of measuring an angle with this instrument is as follows:—Let the two objects be R (that to the right) and L (that to the left). Set the fixed bar to some angle from 10 to 20 degrees to the right of R by the motion of the tube on the axis, and clamp the axis-screw firmly; then, by the motion of the upper bar alone, bisect R with the telescope. Take, with a pair of compasses, the distance between the dots, apply the distance to a scale of chords, and you have the angle between the fixed bar and the object R. Call this angle θ. Now, by the motion of the upper bar alone, bisect the object L. It is clear that, if the distance between the dots were again measured, and the angle deduced, as before, from the scale, we should have a measure of the angle required + θ. But instead of measuring at present, let the telescope be brought back on R, *by unclamping the axis-screw and moving the whole instrument on its axis*; when this is satisfactorily performed, clamp the axis, and bisect L exactly as before, by moving the upper bar and telescope alone. The angle between the bars as deduced from measuring the chord between the dots will now clearly be twice the angle required + θ. Let the operation be performed so many times—eight, for instance—that the bars are nearly in their original position with regard to each other, and let the distance between the dots be measured and the corresponding angle be deduced from the scale of chords, which suppose to be ϕ, ϕ being larger than θ. If this last-mentioned angle had been θ exactly, it is clear that the bar would have come round exactly to its original position after having moved through 360°; but as it has besides moved over an angle $=\phi-\theta$, the whole angle moved through is $360°+\phi-\theta$, which is also eight times the angle to be measured: hence the angle subtended at the spectator by R and L is $\frac{1}{8}(360°+\phi-\theta)$. By continuing this process of stepping several times round, there seems to be no limit to the accuracy with which an angle can be measured, except that which depends on the imperfection of the telescope, the indistinctness of the objects, or the uncertain lateral effect of terrestrial refraction. Mayer used a scale of chords, probably because he was thus able to construct the instrument himself, and could dispense with any circular arc or divisions. We do not see that he has noticed one slight inaccuracy, namely, that as the dots lie in different planes, the distance between them is not the actual chord of the angle required, but is the hypothenuse of a right-angled triangle, the altitude of which is the thickness of the upper bar, while the base is the chord required; but this error is easily allowed for, and, when the angle to be measured by the compasses is of a tolerable size, is scarcely worth considering. If we conceive the plane of the lower bar extended and changed into a divided circle, while the upper bar becomes a vernier at each end, we should probably have the instrument Mayer would have proposed, had it been in his power to employ a tolerable mathematical-instrument maker. Mayer says that he invented this instrument eight years before the publication of his memoir.

The reward proposed by the English parliament for any means by which the longitude at sea could be determined, stimulated Mayer to perfect the method of lunar distances. For the successful solution of this problem two things are required—tables correct enough to predict the true place of the moon at any future time, and an instrument for measuring the distance between the moon and star with sufficient accuracy. Mayer fulfilled the first condition by his celebrated Lunar Tables, one copy of which was sent to the Lords of the Admiralty in 1755, and a later, improved up to his death (1762), forwarded by his widow in 1763. For measuring the distance between the moon and star he proposed an instrument similar to Hadley's sextant, but in which the angle can be repeated or multiplied without intermediate readings off, similar in principle to the instrument just described.

Mr. Troughton says (article 'Circle,' Brewster's 'Cyclopædia') that Bird was employed to make reflecting circles after Mayer's idea, but his dividing was so excellent, that the entire circle was thought useless, and the sextant preferred, as having a larger radius, and being lighter and handier.

In 1787 the Chevalier de Borda published his 'Description et Usage du Circle de Réflexion,' in which he proposed a modification of Mayer's circle, so slight that at first sight it would almost seem trivial, but which gives an unquestionable superiority to this above every other form of reflecting instrument when well made and skilfully and *perseveringly* used. We shall return to Mayer and Borda's construction of the repeating reflecting circle in the article SEXTANT, as those instruments cannot be understood until the principle of reflecting instruments has been explained.

The date of the invention of the repeating circle which is the proper subject of this article, is somewhat uncertain: it is later than that of the reflecting circle. One was constructed in 1787, and employed in connecting the meridians of Paris and Greenwich. (See 'Mém. de l'Academ.'; a Memoir by Le Gendre, 1787; and a memoir by Cassini, 1788.) The 'Connaissance des Tems,' An VI. (1797-8), contains the plate and description of a repeating circle which was made by Lenoir for the astronomer La Lande. When the French government undertook the measurement of an arc of the meridian from Dunkirk to Barcelona, the commission to whom this operation was entrusted resolved to employ the repeating circle.

This is one of the most complicated as well as ingenious of existing instruments, and obtained an immense reputation, from being the only instrument employed in the geodesical and astronomical observations of the great measurement of an arc of the meridian, on which the French have founded their modern system of measures, weights, and money. Since that time the construction has been altered by different artists, but not always with advantage.

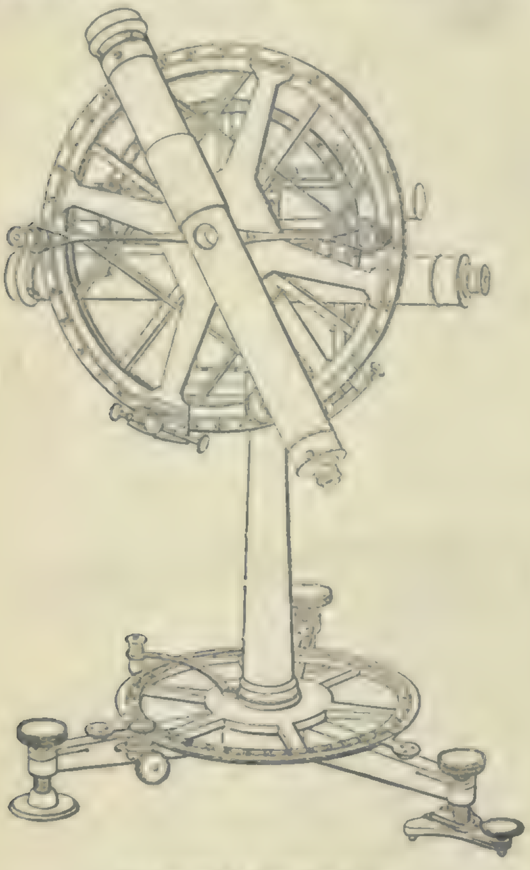

Fig. 1.—Borda's Repeating Circle.

In this figure the general form of the instrument is shown tolerably well, but some of the essential motions are at the back of the circle, and these are drawn on a larger scale in a second diagram. The whole circle turns round on the vertical column, which has an inner axis of steel, with good fittings at the top and bottom. It is usual and proper to make these fittings with great care, but it is not an essential condition to accuracy in the performance of the instrument.

The top of the column finishes in a square bar, to which the upper works and circle are firmly screwed. We shall first describe the motions which are required for astronomical purposes, and point out the rest when the geodesical properties of this instrument are considered. The azimuthal circle is scarcely to be considered a part of the instrument.

The front telescope, its verniers, and clamp, are seen distinctly in front. (*Fig.* 1.) This moves very freely on a spindle within the axis of the circle. There is a level behind, a projecting end of which is seen in the figure. This and its accompanying back telescope are—one a little above and the other a little below the axis of the circle, and revolve on a collar which works on the outside of that axis. These can be fixed in any position by a clamp (also seen in the figure) which embraces the back edge of the circle: the back telescope is for measuring terrestrial angles. Finally, the axis of the circle itself passes through a fitting, on which it also turns freely, carrying telescopes, level, &c., without altering their position in respect to itself. There is a clamp to restrain this motion and fix the circle, the head of which is seen at A, *fig.* 2, and a tangent screw for slow motion at B. This is the weakest and most inconvenient part of the instrument, for the clamp holding so near the axis of motion has little power, and there is scarcely room for getting at the screw head, while the slow motion clamp is out of the way of the observer when he requires it for bisection. The large weight behind is a counterpoise, and the small level above is for setting the circle vertical. There is a clamp at C, which bites on the semicircle to make this adjustment and prevent its being deranged. We will describe the process of observing with the instrument when the object is a star at or near its meridian altitude.

Supposing everything to be adjusted, that is, the axis and circle both vertical, the observer bisects the star with the telescope, he or an assistant having previously brought the level nearly to the corresponding points of its scale. The level is now read off, giving it time to settle if wanted. We suppose its graduation to be in seconds, and reckoned outwards from the centre of the scale. The verniers are read off, the instrument turned half round on the vertical axis, the telescope clamp released, and the star again bisected by the telescope, using its peculiar clamp and tangent screw; and finally, the level is again read off. This operation is precisely the same in all circles having an azimuthal motion, and it is clear that if the verniers were again read off, the difference between the first and second readings would be (after it is corrected for the indication of the level) twice the zenith distance of the star. Let the circle be now reversed, the level clamp and circle-axis clamp be released, and the whole circle moved in its plane till the telescope points to the star, and let the star be bisected again by using the axis clamp and its tangent screw only. The level must be brought back to be horizontal while this is doing, and be actually *clamped* before the final bisection of the star is made. We conceive that this must be done at twice, even by two observers; and it may be done at twice by one, though in a longer time. If the reader has fully understood the process, he will see that the instrument is precisely as at the commencement, except that the telescope and its verniers have travelled over the circle, an arc equal to twice the zenith distance of the star. A repetition of the operation will carry the telescope verniers over four times the distance, and by continuing the process the final arc read off may be made any number of times twice the zenith distance of the star. If the series stops after ten such processes, the arc travelled over is twenty times the simple zenith distance. Let the verniers be now read off, then subtracting the first reading from the last, and dividing by twenty, the result will be the zenith distance of the star, and the errors of division or of reading off will also be divided by twenty. If the number of repetitions which can be taken at one culmination are not thought sufficient to destroy these errors, the series may be prolonged on the following and subsequent nights, starting from the preceding reading without disturbing the verniers, until any number whatever are taken, the only essential condition being that, in reversing, the level is undisturbed both in its attachment to the circle and in its own zero; and that in bringing the telescope on the star by turning the whole on its horizontal axis, the connection between the telescope and circle is permanent. The hour, minute, and second at which each bisection is made are to be noted.

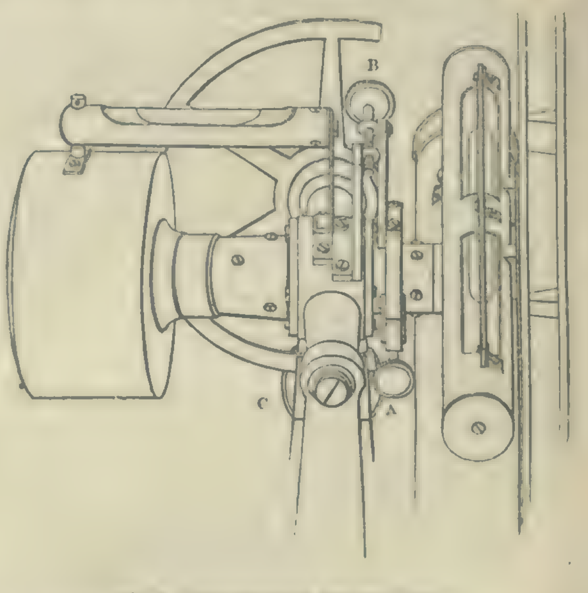

Fig. 2.—Back of Borda's Repeating Circle.

We have said that it is better to read off the level than to attempt to bring the ends of the bubble exactly to the same division, which is really an impossible condition with one observer, and scarcely practicable even with two. The differences should be as small as they can be made with moderate care and in a moderate time; but a well-ground level will measure small arcs better than any graduated limb or even than any small telescope can do, and it is therefore as safe to correct for an error of level as to adjust. The level readings should be registered as towards the object end and eye end, or − and +, along with the times, and the correction may be made to the final arc. It is clear that if the level were always brought to the same divisions, there would be no level error. The effect of a derangement of the vertical axis, which is shown by the level, is calculated as follows:—Let the reading of the level end towards the object be 10″ larger than the reading towards the eye. To correct this, the footscrew towards the observer should be raised 5″, when the two readings will agree; but now the telescope points 5″ *below* its former position, in which it bisected the star correctly. The telescope therefore must be raised, that is, *the zenith distance must be diminished* 5″; hence if 5″ be subtracted from the multiplied zenith distance on account of that observation, the error would be corrected, and so on with every other instance. The rule is, add together all the level readings towards the object end, and prefix −; do the same with those towards the eye end, and prefix +; take their algebraic sum, and divide by twice the number of observations, and the result is the correction to be applied with its sign to the mean zenith distance. This will generally be a very small quantity. As the great difficulty in observing out of a regular observatory is in the reading off, the division of the level might be to every 2″, but numbered as single seconds. These would be better seen, and the divisor of the difference would be the number of observations. When the instrument is very small, and the probable circumstances under which the observer may be placed promise few facilities, the scale may be cut to 10″ only, with bold lines. A mistake of one or two tenths in guessing the subdivisions would be very rare, and scarcely cause a sensible error in the final result.

The circle has been supposed to be adjusted before observing; this is a very simple operation. First place the instrument with the footscrews in their cups, and let that footscrew be towards the observer which rests on the slow-motion piece. This is seen at *fig.* 1, on the right. Place the axis nearly vertical by guess, or, if there is an azimuthal circle, set the plane of that nearly horizontal by a box level. Then place the plane of the vertical circle upright by the cross level, and bring its plane to be parallel with the two footscrews which are *from* the observer; that is, if the object is in or near the meridian, set the circle east and west. Bring the bubble of the main level to the same division at each end by its clamp and tangent screws, and then reverse the instrument (turn it 180° in azimuth). The level is to be brought again to the same divisions, half by its tangent screw, half by screwing the two footscrews an equal quantity in opposite directions. Now turn the circle a quarter round (place it in the meridian according to the supposition), and bring the bubble of the level to its proper position by the third footscrew only. This first attempt at adjustment need only be approximate, but it must be performed over again with considerable nicety. The slow-motion piece is, we believe, due to Borda, and is a very ingenious and useful contrivance for making a coarse screw do the work of a fine one. By placing the footscrew nearer to or farther from the line of the two studs, the elevating power of the screw can be reduced in any proportion, and the finest and slowest motion possible given to the instrument. We have used the slow motion for finally bisecting a star in observing with great comfort. It is more ready to the hand than any other part of the instrument, and the disturbance of the axis is of no importance, as the level must be read off at all events. The approximate bisection is performed by the other screws, and if the observer recollects which way the star is moving, the space through which the instrument is thus moved need only be a very few seconds. The cross level must be originally fixed and adjusted, after the plane of the circle is known to be vertical, either by hanging a plumb-line before the limb, or when the telescope bisects at the same time an object and its image reflected from a fluid. When the cross level is adjusted, the horizontal wire of the telescope may be set right by making a star in the meridian run along it, or else by bisecting a fixed object with it, and afterwards moving the circle in azimuth. The object should run along the wire, and by twisting the wire-plate round may be made to do so.

In the astronomical use of the instrument the azimuthal circle is scarcely required, except to see that you have turned the circle 180° at each reversal. It is convenient to have a coarse division to show this; it is a relief to the eye, and prevents the possibility of catching a wrong star. Any stop which is adjustable and gives notice when the rotation has reached 180° will do. In many of Troughton's repeating circles there is a pin which is pressed by a slight spring against two holes in the azimuth circle, which are 180° apart. This is convenient enough if the observations are confined to Polaris, or a very slow moving star, but wholly insufficient for stars near the equinoctial. It supposes besides that the feet of the instrument are almost exactly placed with respect to the meridian, which is not to be done at once. A bar moving rather stiffly on the vertical axis, and coming against a stop, seems a better contrivance.

For setting to the approximate zenith distance, there is a graduated semicircle attached to the level, which may be seen in the general view. This has its diameter parallel to the level. A slender bar is attached to the object end of the telescope, and passes at the back of the circle; this points out on the semicircle the approximate zenith distance of the star. In many circles which we have seen there are two slips of brass which slide with a little force on the semicircle, and the slight bar above mentioned is brought to *touch* each of these stops alternately. Nothing can be more convenient, but unfortunately, however well the clamps may be made, the contact between the bar and a stop forces the clamp somewhat, and the essential condition of the instrument, that these should be undisturbed, is destroyed. The bar should not be allowed to touch the semicircle at all, but stand freely from it. In this way, by alternately bringing the bar to the equal and opposite divisions, when either the telescope or the level is moved, the telescope will always be at the proper altitude when the level is horizontal. If any one should wish to use the repeating circle as an altitude and azimuth circle, or as a surveying instrument, the wires of the telescope must be set at right angles to the circle axis, by bisecting a distant and distinct object, reading the azimuthal verniers, turning the instrument half round, again bisecting the object, and reading the verniers a second time. If the object be very distant, the azimuth circle may be set to the mean of the readings, and the object bisected by the horizontal screws, which draw the wire-plate; but if very great accuracy is required, either two marks must be set up having the same distance from each other as lies between the two positions of the axis of the telescope, or the angle which this last space subtends at the distant mark must be allowed for. The instrument is not fitted for nice observation with the azimuth circle.

We have now explained the chief astronomical use of Borda's circle, which is that of determining the altitudes of stars upon the meridian by several observations near the meridian. There is a correction to be applied to the mean result, which is easily computed when the approximate latitude and exact time are known. The formulæ and tables required may be found in several works on astronomy, in Schumacher's 'Hülfstafeln,' p. 38, and Baily's 'Tables,' p. 154. The length of time during which the observations may be carried on depends on the altitude of the star and its proximity to the pole. Polaris might be observed safely beyond 36^{m} on each side the meridian, which is the extent of the present tables, and, in these latitudes, stars in or below the equinoctial for fully half an hour on each side. It is supposed that the error of the clock is well known, but even this may be wrong to a small amount without causing much error, if the number of observations on each side the meridian and the hour angles are nearly equal.

The repeating circle may be very well used for getting the time either by equal altitudes, or by absolute altitudes with one or two repetitions. For this purpose there should be three or five horizontal wires, and the instrument should be previously carefully adjusted. The instrument must be moved in azimuth, so that the star passes each wire near the centre, and nothing should be touched which affects the level. For illumination by night, there is an opening with a reflector in the centre of the telescope. This is objected to as weakening the telescope, but the other mode of illuminating by a small central reflector, or outer ring in front of the object glass, is inconvenient. Perhaps by taking a longer hold of the telescope and strengthening the intervening portion of the tube, the former convenient arrangement may be preserved without sensible loss of strength. The repeating circle, on Borda's construction at least, cannot be well employed in observing the sun without very careful screening. The level is so perpetually changing its zero, when exposed to the sun, that there is no possibility of saying what the instrumental zenith is.

One of the first operations which the observer must engage in, is to determine the scale of his level at different temperatures, and then he may, for small deviations, use the indications of the level, instead of worrying himself and losing his time in attempting to produce a perfect adjustment. The value of the scale is thus measured:—Bring the bubble towards one end, bisect a very well defined object with the telescope, and read off both scale and verniers. Then, by the slow-motion foot-screw, bring the bubble towards the other end, bisect the object again by the telescope, and read off the level scale. Now bring the bubble to its original position by the circle-axis clamp, and the telescope on the object by its own clamp, when everything is as at starting, except that the telescope has moved over the circle the sum of the angular motions pointed out by the level. This may be repeated till a sufficiently accurate value is got for the *whole* scale. To try the equality of the divisions of the level, place the foot-screw near the line passing through the studs of the slow-motion piece, and note the motion of the level for every *whole* revolution of the screw.

For geodesical purposes Borda's circle is an excellent instrument, as the great French survey proves, but as the same advantages can be obtained by a different application of the repeating principle, it is now but little used. For an account of its employment and the directions for its use we refer to Delambre's 'Méthodes Analytiques pour la Determination d'une Arc du Méridien,' &c., Paris, An VII.; in the 'Discours Préliminaire,' by the same author, contained in the 'Base du Système Mètrique Décimal,' vol. i. Paris, 1806.

Borda's repeating circle possesses two most valuable properties: mere errors of division may be diminuted by sufficient patience; and the fatigue of reading off the divisions, the most ungrateful part of an observer's task, is greatly reduced. Hence, it may be asked, why is not the repeating circle in general use as a portable astronomical instrument? We should answer that, in the first place, the construction of Borda is by no means satisfactory for an *astronomical* instrument; it is weak, and heavy, and rickety. But if a *portable* astronomical circle is wanted, and to this class of instruments we should confine the repeating circle, we think the following alteration should be adopted. The telescope hangs loosely from its centre,[*] and whatever care may be taken by the artist, the flexure of each end must be considerable, probably different, and possibly varying from time to time with variations in the temperature. It should be grasped by two strong collars near the ends of a diameter of a vernier circle, and the telescope might then be safely extended three or four inches each way beyond the divided circle. Again, the axis clamp which holds the vertical circle should be fixed on the pillar and embrace the rim of the inner circle, the clamp of the level (for no second telescope is wanted) might be at the back, above, and quite out of the way. The whole circle should be brought as close to the upright pillar as possible, and perhaps its axis had better be fixed by the maker permanently at right angles to the pillar. This would take away much weight and give great firmness to the whole instrument.

It must however be admitted that unless there are two intelligent observers, or unless the base on which the instrument stands is so steady as to prevent the possibility of any derangement when the observer moves from the telescope to read the level, that errors may creep in, though not, as it seems to us, greater than in all other instruments *not* reflecting. We have previously cautioned circle observers, and the warning cannot be too strongly pressed upon our countrymen at least, that the *level* must *always* be noted contemporaneously with the *bisection* of the star. If the foundation of the instrument is immoveable, this will be the same as the level a minute after bisection, and so only one observer be required. But if the position of the instrument is affected by the weight or motion of the observer, the *level* after bisection is no test of the position *at* bisection, and two observers are absolutely necessary. In Borda's repeating circle, where the clamp is necessarily imperfect from the shortness of its bearing, it is impossible to move the front telescope without shifting the circle a little at the same time; but this is of no importance, for the level shows the change, and the reading off of the level, when properly applied, corrects this error.

In judging of the repeating principle as applied to any instrument, attention should be paid to the perfect independence of the telescope and level with respect to each other, and to their perfect connection with the circle when they are clamped to it. In some instruments a sort of repetition has been attempted by having the circle turn freely on the telescope axis, and clamping it alternately to the telescope and to a vernier circle which carries the level. It seems difficult in any such construction to secure the immoveability of the circle while clamping and unclamping is going on, and the construction has, we believe, gone out of use. There are some precautions which should be observed in every repeating circle, which we shall describe in reference to Borda's construction. Besides the perfect independence of the level, the telescope with its verniers and clamps should be perfectly self-balanced, so as not to apply any force to the clamp in any position; the telescope should be moved on the circle by two fingers pressing in opposite directions towards the extremities; the circle should be turned in its own plane by laying hold of the circle itself, and so gently that no jar can take place, or any springing back or forward of the telescope or its verniers from the moment of inertia: finally, the level must have time to settle before it is read off. When these precautions are duly observed, great accuracy may be obtained; in two instances, to our knowledge, where the latitude has been determined by unexperienced but intelligent observers, the results even of a single night have come within 1" of the truth.

It may be worth mentioning that with the circle of Borda the measurements may be made by moving the telescope *contrary* to the order of divisions, that is, if the first observation is made with the face to the right hand instead of the left. There is no advantage in this modification, except perhaps that, as the screws are handled a little differently, any discrepancy between an angle measured in the two ways would show an error in one or both the methods. It would be advisable, where several series are taken, to vary the direction in which the telescope is brought to its new position, and that in which the circle is turned upon the star. The tangent screw might be worked either constantly one way or the other, or alternately, but we should not expect any sensible difference in the results if the instrument is well made and the observers careful. If two steady observers can be found, the double altitude of any star may be repeated, with the genuine Borda and its two telescopes, exactly as a terrestrial angle, that is, by measuring the angle between the star seen directly and by reflexion from mercury. This would in theory appear to be the most perfect application of the instrument, as flexure has no effect upon the angle measured, being equal and in the same direction in both positions of the telescopes. The level is not wanted for this observation at all, but the circle must be set truly vertical. A single observer might indeed make the same observation with one telescope, as the level would show and measure any shifting of the circle. And here again the effect of flexure is eliminated from the observed double altitudes. Finally, double nadir distances may be observed of a star reflected from a mercurial horizon, exactly as double zenith distances are observed in the ordinary method. This last species of observation may have the advantage of being sometimes more convenient, but the chief reason why it is pointed out is, that the effect of flexure upon double nadir distances is equal, but in a contrary direction, to its effect on double zenith distances; the observer has thus an easy mode of ascertaining whether flexure exists, and of measuring its amount and law. We suppose that the apparent nadir distance of a reflected star is the same as the zenith distance of the star seen directly. The horizontal points of all the large circles which we know, vary to some extent with the altitude of the star observed, which seems contrary to what is here supposed. This last mentioned discrepancy is one of the most perplexing points in modern practical astronomy. The amount is, however, so small as scarcely to vitiate sensibly any conclusion drawn from reflected observations with so small an instrument as a repeating circle.

What precedes refers almost entirely to the repeating principle when applied to measurements in altitude. Instead of the circle of Borda and its two telescopes, later artists have given a motion in azimuth to their theodolites, in addition to the motion of the telescopes and verniers, by which the angle can be measured precisely as in Mayer's original instrument. But in several instruments which we have seen there is a considerable probability of disturbing the circle clamp while moving the telescope or using its tangent screws. It is to secure the detection of any similar motion that a watch telescope, as it is called, is frequently added to English theodolites, and is indeed required for many, spoiled as they are by an unnecessary adjustment to zero, to save indolent or ignorant surveyors a simple subtraction. A watch telescope can scarcely be applied to a repeating theodolite, and we think that the repeating tripod may be so made as to be free from any objection. This was first constructed by Mr. Dollond on the suggestion of the late Astronomer Royal, and has been found very useful in the trigonometrical survey of Ireland.

The three foot screws of an ordinary theodolite are placed in the three notches which are seen on the table of the tripod. This upper part turns heavily on a stout short centre, it is fixed by a clamp at A, and there is a tangent screw at B for giving slow motion. The steady action of the tangent screw is secured by a spring at C. It is evident that if, in using an ordinary theodolite, R (the right hand object) is first bisected, the circle read off, and then L (the left hand object) is bisected, the circle being again read off, that the difference between the two readings is the angle to be measured, *if the instrument has not been shifted*, and if the bisection, reading off, &c., are perfect. Now suppose the whole instrument to be taken up and set down exactly concentric with its first position, without any other alteration, but with the telescope on R; if L be a second time bisected, the difference between this latter and the preceding reading will be also the angle to be measured, and therefore the vernier will have passed over twice the angle, reckoning from the beginning. If, instead of this impracticable taking up and setting down again, the stand on which the theodolite rests can be turned round concentrically so that R is bisected by the telescope, the theodolite itself being untouched, it is clear that the operation is equivalent to that just described, and consequently that the telescope being brought on L by its own motion, the measure is obtained of twice the angle required, and the process may be continued *ad libitum*, until the errors of read-

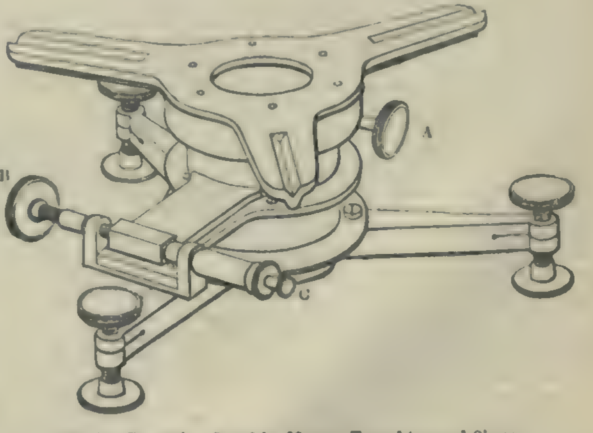

Fig. 3.—Repeating Stand by Messrs. Troughton and Simms.

---

[*] If the object and eye end bend equally, there is no alteration in the direction of the line of sight; the only evil is that the oblique incidence of the rays on the object glass deforms the image when the obliquity is considerable. The German artists of Reichenbach's school apply levers to telescopes hung by the middle, in order to counteract flexure. We prefer, on the whole, obtaining a maximum of stiffness, and then determining the effect of flexure which must be allowed for. There is no possibility of avoiding the investigation in any case where accuracy is demanded. Gambey takes a longer hold of the telescope, but in providing a motion for surveying when the circle is horizontal, we think he has lost something in stability when the circle is vertical.

ing off and of division are eliminated. The only precaution to be observed is, that the stand must receive no angular motion from the motion of the telescope, and this is easily effected by giving a certain massiveness to the stand and a considerable heaviness to its motion, while the telescope and its verniers revolve as lightly as possible. The observer should satisfy himself as to this perfect independence of the two motions and the stability of his repeating tripod by taking a set of twenty repetitions of an angle, always moving the telescope forward in the order of the divisions, and a second set of twenty of the same angle, carrying the telescope round the contrary way. The two results should agree if the stand has no motion; and if they do not, the upper motion must be lightened or the lower be loaded till they do agree. We should not feel satisfied to use the repeating stand if a motion of the telescope a little ruder than necessary affected its position although unclamped; and the stand which is here figured fulfilled this condition very well with a 12-inch theodolite. As the absolute coincidence of the axes of the tripod and theodolite cannot be obtained, the angle should be repeated at least once round the circle, and, if the case requires it, until the multiple angle is very nearly equal to one, two, or more circumferences. The original repeating tripod as designed by Mr. Pond was considerably higher than that figured here. (See Pearson's 'Practical Astronomy,' plate xxix., fig. 7, and vol. ii., p. 513.) A little greater nicety is thus given to the adjustment of the vertical axis of the tripod, which is not necessary, and the snugness of the present stand is, we think, more than an equivalent. The axis of the tripod must first be set vertical, either by a level of its own or the theodolite level, exactly as is described in the adjustment of the vertical column of Borda's circle. For the subsequent adjustments, &c., of the theodolite, see THEODOLITE.

REPETEND, the part of a CIRCULATING DECIMAL which is perpetually repeated. The word, however, means simply *to be repeated*, and is so little used in the above sense that it might be advantageously employed with more generality.

REPLEVIN (*delivrance de namps, replegiatio*). In the middle ages the performance of legal duties was enforced by taking the person, the lands, or the goods of the defaulter into the custody of the party authorised to enforce the performance of such duties. When such a taking was effected, the party was said to be distrained (*districtus*, put under compulsion), by his body, his lands, or his goods, to do the act in respect of which he was supposed to have made default. [DISTRESS.]

Upon a distress being effected, the body, land, or goods, as the case might be, of the distrainee remained in the custody of the distrainor until the act for which the enforcing of the distress had been made was performed: unless the distrainee brought the question of the legality of the taking before a competent tribunal, in which case he might either await the result of his legal proceedings, or, if he was desirous of obtaining a more speedy liberation of the thing distrained, he might replevy it by giving a pledge or security to replace it in the custody of the distrainor in the event of the legal decision being in favour of the latter.

The alleged defaulter might contest the legality of the taking in an action of trespass. [TRESPASS.] But in this form of action he could recover damages only. He would not be entitled to the liberation of his body, lands, or goods, as the case might be, pending the suit; nor indeed when the suit had terminated in his favour, could he by any proceeding which could be resorted to in the action of trespass be relieved from the distress. The remedy by which a party was to recover his liberty or the property distrained, and also damages for the temporary detention, was an action of replevin. Where the person of the plaintiff was taken, his remedy was by an action of replevin in a peculiar form, which, taking its denomination from the writ by which it was commenced, was called *de homine replegiando*. This proceeding was however surrounded by so many difficulties, rendered perhaps indispensable by the necessity of preventing criminals from using it as a means of evading justice, that it has now become obsolete in England, parties preferring to obtain their discharge by the more summary process of habeas corpus. [HABEAS CORPUS.] The great mass of the cases of *homine replegiando* in the old law books arose upon the seizure and detention of persons whom the parties seizing claimed as their fugitive villeins [VILLEIN], and this process was frequently resorted to in Jamaica and other slave colonies. The seizing of the lands of a defaulter by way of distress has long ceased to be practised.

Formerly not only lands but incorporeal hereditaments were the subjects of replevin, of which a remarkable instance occurred in the reign of Edward III. ('Parliament Rolls,' vol. i., 45.)

The third form of replevin, and the only one now in use, is replevin of goods, called in the old statutes *replegiari de averiis*, cattle (in law Latin, averia) being the species of goods which usually formed the subject of a distress.

If the goods of a party were taken out of his possession against his will, he was entitled to a writ of *replegiari facias*, by which the sheriff was required to cause the goods to be replevied, that is, restored to the owner upon his giving pledges for the prosecution of his action, and for the return of the goods to the distrainor in case a return should be adjudged. As the right of the party from whom the goods are taken to have the possession restored to him by replevin, depends upon the property belonging to him—if the taker of the goods claim them as his own property, the power of the sheriff is suspended, until the party has sued out a writ *de proprietate probandâ*, by which the sheriff tries whether the goods are the property of the plaintiff or of the defendant; and if they are found to be the property of the plaintiff, then to replevy them; if of the defendant, the plaintiff's claim to be restored to the possession of the goods remains in suspense until the termination of the action.

A replevin does not lie for goods taken in execution, or for goods seized for a debt to the crown. In a very intemperate speech, addressed by Hyde, afterwards Lord Clarendon, to the House of Lords, upon a charge against the barons of the Exchequer, for enjoining the sheriffs of London not to execute a writ of replevin of goods seized by the officers of the custom-house in respect of unpaid tonnage and poundage, he is stated to have said, in the course of his argument, "We all know a replevin lies against the king, if the goods be (be not?) in his own hands." ('Rushworth,' part 2, vol. ii., 1361.) Though this strange assertion has been regularly transcribed by succeeding writers, it appears to be altogether unfounded. The replevins sued out for goods seized in respect of tonnage and poundage would issue against the officers as for goods seized by them in respect of debts claimed to be due to the crown. But goods seized for the king's debts cannot be replevied without the special mandate of the king or of the barons of the Exchequer. Still less could replevin be brought in respect of goods in the actual possession of the king, and upon an allegation of their having been wrongfully taken by him.

Replevin does not lie for goods taken in a foreign country, though afterwards imported here.

If upon a distress taken by the superior landlord upon premises in the possession of an under-tenant, the mesne or intermediate tenant puts his cattle in the place of those distrained, as by law he was allowed to do, he might replevy the goods so substituted, though the latter were never distrained.

Replevin lies notwithstanding an express agreement that the landlord shall be at liberty to distrain and hold the goods against pledges (that is, notwithstanding a tender of pledges) until the rent be paid; for goods cannot be made irreplevisable by the mere agreement of the parties.

Executors may maintain replevin for the goods of the testator taken in his lifetime, and a husband may bring replevin alone without naming his wife, for the goods of the wife taken before the marriage; as the property in the goods passes to the executors, and to the husband respectively, notwithstanding the seizure and detention.

A person may in some cases support a replevin without being the owner of the goods, as where the plaintiff is the bailee of the goods taken. [BAILMENT; PLEDGE.]

The writ of *replegiari facias*, which must have been sued out of the Court of Chancery, was attended with great inconvenience and delay at a period when the chancery followed the person of the king, and hence it was provided by the statute of Marlbridge, (1267) that the sheriff should, after complaint made, deliver the goods without hindrance or refusal of him who took them, and by 1 and 2 Philip and Mary, c. 12, every sheriff was required to appoint four deputies dwelling not above twelve miles distant from one another, to make replevies and deliverance of distresses. Under these two statutes distresses continued to be replevied, until quite recently; when by the statute 19 & 20 Vict. c. 108, the powers of the sheriffs were transferred to the registrars of the County Courts [COUNTY COURTS], who now grant replevins, and take security from the replevisor for the prosecution of an action either in the County Court or in one of the superior courts to try the validity of the distress. This bond is taken under the statute 11 Geo. II., c. 19, s. 23, requiring sheriffs and other officers having authority to grant replevin, in every replevin of a distress for rent, to take from the plaintiff and two responsible persons as sureties a bond in double the value of the goods distrained, with a condition for prosecuting the suit with effect and without delay, and for duly returning the goods and chattels distrained in case of a return being awarded.

By this statute this bond may be assigned to the avowant (the party who took the distress in his own right), or to the person making cognizance (the party acknowledging the taking of the distress on behalf of some other person), and the assignee may sue upon it in the event of the condition of the bond not being performed.

In the action which follows the replevin, the plaintiff declares against the defendant for the taking of the goods and chattels of the plaintiff, at such a time and in such a place, and claims damages. To this declaration the defendant may plead non cepit, whereby he admits that the goods belong to the plaintiff, and denies the taking only; or he may plead that the goods do not belong to the plaintiff, thereby admitting that he took and detained them.

But in ordinary cases, the defendant avows in his own right, or makes cognizance as bailiff to his employer, for rent, or for some other duty or cause, for which a distress is allowed by law [DISTRESS], in doing which he may set up any ground of distress, though differing from that expressed at the time when the distress was made.

The plaintiff may reply to the defendant's plea as in other cases [PLEADING]; but inasmuch as an avowant, or a person making cognizance, is not merely a defendant, but a party seeking to recover something, the plaintiff's answer to an avowry or cognizance, which is in the nature of a declaration for the right or duty withheld, is called a plea in bar to such avowry or cognizance; the defendant's answer to which plea or bar is called a replication.

Where there is judgment for the defendant, or the plaintiff is nonsuited, the judgment directs that the defendant shall have the goods restored to him without being again subject to being replevied, which is called a return irreplevisable.

If upon a replevin, or upon a writ of retorno habendo after judgment, the sheriff returns that the cattle, &c., are driven away (eloigned, elongata) a writ may issue commanding the sheriff to make reprisals by taking the cattle, &c., of the distrainor, and to detain them until he is ably to replevy the cattle, &c., of the distrainee. This process, which is now nearly obsolete, was called a capias in withernam, or a capias by way of counter-taking, from *wither* (against; in German, *wider*) and *nam*, a taking or distress. A special action of trespass also lies for removing a distress so that it cannot be replevied. This latter offence was formerly called a "vee," or "vetitum namium," by which term is to be understood, not, as might be supposed, a forbidden distress, but a distress forbidden or refused to be replevied." (2 'Inst.', 140.)

If after goods have been replevied, and before the suit has been decided, the defendant makes another distress for the same cause, such second distress is called a recaption, and the course is to sue out a special writ for the restoration of the goods and for the punishment of the recaptor; since, whether the first taking was right or wrong, the defendant is not justified in thus anticipating the judgment of the court. It is not material whether the second taking be of the same goods or of other goods, provided they belong to the same party, and are taken for the same cause; but if the landlord distrain the goods of A, who replevies, and afterwards, finding the goods of B upon the land, he distrains them for the same rent, no writ of recaption lies. B can only replevy or bring an action of trespass or trover.

At common law, if the plaintiff was nonsuited, although the defendant became entitled to a return of the goods, yet the judgment was not that the return should be irreplevisable, as in a judgment upon a verdict where the right had been tried. The plaintiff might have again sued out a replevin, and so after several successive nonsuits. To put an end to this vexatious proceeding, the statute of Westm. II. c. 2, gave the plaintiff a writ of second deliverance instead of a new replevin, in which, if the plaintiff in any manner fail in his suit, the defendant will have judgment for a return irreplevisable. In other respects the proceedings in the action of second deliverance are similar to those in the action of replevin.

REPLICATION. [PLEADING.]

REPORTS (in Law) are relations of the proceedings of courts of justice. They usually contain a statement of the pleadings, the facts, the arguments of counsel, and the judgment of the court;—the object being to establish the law, and prevent conflicting decisions, by preserving and publishing the judgment of the court, and the grounds upon which it decided the question of law arising in the case.

The earliest reports extant are the 'Year Books.' It is said that some few exist in MS. of the reign of Edward I. and a few broken notes are to be found in Fitzherbert's abridgment. A series of these commences, and are now printed, from the reign of Edward II. They were published annually, which explains their name, from the notes of persons, four in number, according to Lord Coke, who were paid a stipend by the crown for the purpose of committing to writing the proceedings of the courts. These early accounts of cases are very short, abrupt, and often confused, especially from the circumstance that it is frequently difficult to ascertain whether a judge or a counsel is speaking.

The Year-books continue, with occasional interruptions in their series, down to the reign of Henry VIII. The omission during the time of Richard II. has been attempted to be supplied by Bellewe, who collected and arranged the cases of that period which had been preserved by other writers. The Year-books are wholly written in Norman-French, although by the 36 Edw. III., stat. 1, c. 15, it was enacted that all pleadings should be in the English language, and the entries on the rolls in Latin. This dialect continued indeed to be used as late as the 18th century; the last which appeared were those of Levinz and Lutwyche; the former in 1702, the latter in 1704. The Year-books of later date have more continuity of style and fulness of discussion; cases are cited, and the decision of the court is given at greater length, with more solemnity and clearness. About the end of the reign of Henry VII. it is probable that the stipend was withdrawn. Only five Year-books exist for the ensuing reign, and none were published after it. Their place was shortly afterwards supplied by reports compiled by private individuals, but subject for some time to the inspection of the judges, whose testimony to the fitness of the reporter is prefixed to the Reports. This however soon became a mere form, as appears by the statement of Lord-Keeper North, who speaks slightingly of the Reports in his time as compared with his favourite Year-books.

During the reign of Henry VIII. and his three successors, Dyer, afterwards chief-justice of the Common Pleas, took notes as a reporter. Benloe and Dalison were also reporters in these reigns. In the time of Elizabeth many eminent lawyers reported the proceedings of the courts, and, from the ability with which they acquitted themselves, added to the previously unsettled state of the law, the Reports of about this period have acquired very great authority. Anderson, Moore, Leonard, Owen, Coke, and Croke, all lived about this time. But the first printed accounts of cases published by a private hand are those of Edmund Plowden, the first part of which appeared in the year 1571, under the title of 'Commentaries.' A few years afterwards the executors of Dyer published the notes of their testator under the express name of 'Reports,' being the first published under that title. These were followed, in 1601 and 1602, by those of Sir Edward Coke, which, from their excellence, have ever been dignified by the name of 'The Reports.' During this time reporters did not, as they have done in more modern times, confine themselves to one court. In the same volume are found reports of cases in chancery, in the three superior courts, the court of wards, &c. During the reign of James I., Lord Bacon and Sir Julius Cæsar suggested to the king the appointment of two officers for the purpose of taking notes and minutes of proceedings in the courts. James acceded to the suggestion, and a copy of his ordinance for their appointment, at a salary of 100*l*. each, is extant. (Rymer's 'Fœdera,' 15 Jac. I., 1617.) The ordinance does not, however, appear to have been acted upon, and Reports continued to be compiled and published by private hands only.

The English language was first used by reporters about the time of Elizabeth. Lord Coke employed it in his 'Commentary upon Littleton.' In his preface he states why he thought it convenient to do so; and adds that his conduct was not without precedent. From the period of Elizabeth down to the present, Reports have been published of the proceedings in all the courts. Coke, in his day, thought the following distich applicable:—

> "Quæritur ut crescunt tot magna volumina legis;
> In promptu causa est, crescit in orbe dolus."

This is curious as evidencing the number and fecundity of reporters at that time. North also complains of the great number of Reports.

(Coke's *Reports*, Preface to part 3; Dugdale's *Origines Juridicales;* Reeves's *History of the English Law.*)

REPRESENTATION. [DESCENT.]

REPRIEVE (from the French *repris*, withdrawn), in criminal law, means the withdrawal of a prisoner from the execution and proceeding of the law for a certain time. Every court which has power to award execution, has also power, either before or after judgment, to grant a reprieve. The consequence of a reprieve is, that the delivery or the execution of the sentence of the court is suspended. A reprieve may proceed from the mere pleasure of the crown expressed to the court, or from the discretion of the court itself. The justices of jail delivery may either grant or take off a reprieve, although their session be finished, and their commission expired. A reprieve proceeding from the discretion of the court is usually granted when, from any circumstance, doubt exists as to the propriety of carrying a sentence into execution. This doubt may be created either from the unsatisfactory character of the verdict, the suspicious nature of the evidence, the insufficiency of the indictment, &c., or from the appearance of circumstances favourable to the prisoner. When a reprieve has been granted with a view to recommend to mercy a prisoner capitally condemned, a memorial to that effect is forwarded to the secretary of state, who recommends the prisoner to the mercy of the crown. Where it has been granted by reason of some doubts in point of law as to the propriety of the conviction, the execution of the sentence is suspended until the opinion of the judges has been taken upon it. The sentence is then executed or commuted in accordance with their opinion.

There are two cases in which a reprieve is necessarily granted. One is where a woman who has been capitally convicted pleads her pregnancy in delay of execution. Where such a plea is made, the judge must direct a jury of matrons to inquire of the fact; and if they find that she is quick with child, the execution is delayed, either till after her delivery, or proof by lapse of time that she was not pregnant. The other is where a prisoner appears to have become insane between judgment and the award of execution. In such case a jury must be sworn to inquire whether he really is insane. If they find that he is, a reprieve must be granted.

If the reprieve is sent by the secretary of state, it is under the sign manual of the sovereign.

REPUBLIC is derived immediately from the French *république*, and ultimately from the Latin *res publica*. The Latin expression *res publica* is defined, by Facciolati, to be "res communis et publica civium una viventium," and corresponds very closely with the English word *commonwealth*, as used in its largest acceptation for a political society. The Latin word *res publica* might be applied to a community under a monarchical government; thus Augustus is said in a passage of Capito, a Roman lawyer, to have governed the *res publica* (Gellius, xiii. 12); the word, however, was more applicable to a society having a popular government than to a society having a monarchical government; thus Cicero denies that the name of *res publica* can be properly given to a community which is grievously oppressed by the rule of a single man: "Ergo illam rem populi, id est rem publicam, quis diceret tum, quum crudelitate unius oppressi essent universi; neque esset unum vinculum juris, nec consensus ac societas coetus, quod est populus" ('De Rep.,' iii. 31).

A *republic*, according to the modern usage of the word, signifies a political community which is not under monarchical government, or, in other words, a political community in which one person does not possess the entire sovereign power. Dr. Johnson, in his dictionary, defines a republic to be "a state in which the power is lodged in more than one." Since a republic is a political community in which several persons share the sovereign power, it comprehends the two classes of aristocracies and democracies, the differences between which are explained under ARISTOCRACY and DEMOCRACY.

The word *republic* is sometimes understood to be equivalent to *democracy*, and the word *republican* is considered as equivalent to *democrat*; but this restricted sense of the words appears to be inaccurate; for aristocratic communities, such as Sparta, Rome in early times, and Venice, have always been called republics.

REPUBLICATION. [WILL AND TESTAMENT.]

REPULSION is that power by which bodies or the particles of bodies are made to recede from one another. Both attraction and repulsion exist in all the particles of material substances, and seem to be properties by which those particles act upon one another when not in contact. The cause of these actions will probably be for ever unknown to us; and the terms are only applied in conformity to the phenomena exhibited. At all sensible distances, bodies, small and great, except in certain states with respect to electricity or magnetism, attract one another; and the intensity of the attraction varies inversely as the square of the distance between the bodies. But the phenomena of light, and of elasticity in general, show that at distances which are not appreciable by the eye (perhaps such as are less than $\frac{1}{2000}$ inch) both attractions and repulsions take place. [ATTRACTION.]

In his researches concerning the phenomena of light, Newton, having brought at one time a hair, and at another the edge of a knife, near a small beam of light in a darkened room, found that the particles of light were made to deviate from the rectilinear direction, as if attracted by a force which diminished with the distance of the ray from the hair or knife. The shadow of the latter was bordered with three coloured fringes, of which the nearest to it was formed by inflected rays passing at a distance rather greater than $\frac{1}{[illegible]}$ inch from the knife-edge; and the second and third fringes by rays inflected respectively at greater distances. ('Optices,' lib. iii.) [DIFFRACTION OF LIGHT.] From these phenomena Newton was led to the opinion (which he proposes as a query) that all material bodies might be assemblages of particles in equilibrio between their mutual attractions and repulsions. He imagined also that a subtle ether, pervading material bodies, was the immediate agent in producing such attractions or repulsions, together with all the circumstances of cohesion, and also those of chemical, magnetical, and electrical actions. The phenomena of nature seem to justify the supposition than an ether pervades all bodies; but it must be admitted that the hypothesis of Newton only removes the difficulty concerning the actions of the particles of bodies a step further, since we are equally at a loss to account for the existence of the powers in those particles, and in the ether itself.

The reality of a distance between the particles of bodies, whether solid, fluid, or gaseous, admits of no question; for the differences in the densities of these classes of bodies can only be conceived to arise from the different extent of the intervals between the particles. [HEAT.] By the process of cooling, all bodies, with certain exceptions in particular cases, become contracted in volume; and the mixing of two given volumes of different fluids (as water and sulphuric acid) produces a volume less than the sum of the two separate volumes. These effects manifestly depend upon the approach of the particles to one another, and are therefore inconsistent with the supposition that they were originally in contact.

It is natural to ask if there be such a thing as mathematical contact in nature, and it may be answered that we have no evidence of such a condition. [COHESION.] Besides the continual diminution of volume produced in the cooling of bodies, the Newtonian experiment of pressing a convex lens of glass upon the surface of a glass mirror affords evidence that the lens, at the point of nearest approach, and under a very great pressure, is not in contact with the mirror; and it has been supposed that the distance between them, at that place, is then not less than $\frac{1}{[illegible]}$ inch. (Robison, 'Mechan. Phil.') It seems to follow that a vast force of repulsion must be in action between the particles of bodies when they are as near together as mechanical power can bring them; and it can be easily conceived that such repulsive force may be the immediate cause of the sensation of touch.

It has been said that the mixture of certain different fluids produces a diminution of volume; but it must be observed that a contrary effect frequently takes place. Some of the metals, when mixed together in a melted state, produce a volume greater than the sum of the component volumes; and melted metals, on becoming solid, like water on being frozen, expand in volume. The latter effect may arise from the crystals, on being formed, placing themselves across one another so as to leave comparatively large intervals; but the other can only be caused either by a diminution of the attractive power which the particles exert on one another, or by its being changed into a power of repulsion. One of these latter circumstances must also be the cause of the great augmentation of volume which takes place when the components of some bodies are disengaged from each other. It is said that if the parts of olefiant gas were separated, the sum of the separate volumes would be four times as great as the volume of the compound; that is, two volumes of hydrogen and two of carbon vapour are condensed in olefiant gas into the space of one volume.

It is right to observe that the word *repulsion* is often applied to phenomena which are in reality the results of attraction. A small quantity of quicksilver being laid on a glass plate assumes a spherical form, instead of spreading over it in a thin surface; and this was once supposed to arise from a repulsive power in the glass, whereas it is owing to the attraction of the particles of quicksilver for one another being greater than the attraction of the glass for the quicksilver. Again, when a small sewing-needle is placed on the surface of water, it remains there without sinking, and the water is depressed about the needle as if it were repelled by the steel; in fact, however, the trough is caused by the weight of the needle, which displaces the particles of water, but is not great enough to overcome their attraction for each other. Also, when two balls, one of them of glass, which is capable of attracting water, and the other of burnt cork, which is not, or only in a very small degree, are placed near one another in water, the latter seems to be repelled from the former; but the cause of the phenomenon is that the ring of elevated water about the glass assumes on the exterior a conical surface, so that when the cork ball is brought near enough to the other to be partly on the slope, it immediately slides off by its gravity.

The elasticity of bodies is a result either of attractive or repulsive powers, or both. For example, when a steel rod is bent, the particles on one side will be forced towards, and on the opposite they will be drawn from one another; in recovering itself, a force of attraction will be exerted on the latter side, and of repulsion on the other; and this may be considered as an evidence that in the insensible spaces between the particles of bodies attractions and repulsions prevail according as the distances between those particles are varied. While the change of figure in the rod is small, so that the displacement of any two particles is but a small part of their whole distance from one another, the attractions and repulsions exerted by the force applied are proportional to that force; and upon this principle depends the observed isochronism in the oscillations of a watch-balance, whatever be the extent of the arcs of vibration. The expansions of solids and fluids by heat, and the elastic powers of gas at different temperatures, are consequences of the repulsions residing in the particles of caloric, or induced by the latter in those of the bodies with which they are combined. [ELASTICITY; GAS; HEAT.] The repulsive power existing in the air which is condensed in nitre, produces, on being combined with heat, a velocity of expansion equal to about 7000 feet per second; and the force of pressure resulting from it is thought to be equal to 2000 times the pressure of the atmosphere. (Hutton, 'Tracts.') The repulsive force which produces some of the electric explosions in the atmosphere is supposed to be much greater. But the forces both of attraction and repulsion by which the particles of light are deflected from their course when they impinge on a refracting or reflecting surface are enormous; and Sir John Herschel computes that they exceed the force of gravity in the ratio of 2×10^{44} to 1. This is on the hypothesis of radiation; and that philosopher observes that on the undulatory hypothesis the numbers are equally high.

The circumstances of electrical attractions and repulsions are shown in the article ELECTRICITY; and the results of experiments prove that the intensities of these forces in the electric, galvanic, and magnetic fluids, like that of general attraction, vary inversely as the squares of the distances of the bodies.

Boscovich has ingeniously represented the series of alternate attractions and repulsions supposed to be experienced by a particle of matter within the very small distances between that particle and another, by a curve consisting of several bends crossing and recrossing an axis in points at various distances from the origin, which may be supposed to be the place of the second particle above mentioned. The ordinates of this curve on one side of the axis represent attractions, and those on the other side repulsions; the places of crossing being supposed to be those at which the first particle would be at rest. Beyond the small distance above mentioned, this axis becomes an asymptote to the curve, and the ordinates of the curve here represent the general law of attraction (the inverse square of the distances). Near the origin of the axis the ordinates represent repulsions; and these ordinates constantly increase till they become infinite, so that a right line drawn through the place of the second particle, perpendicular to the axis, is an asymptote to this branch of the curve.

REQUEST, COURTS OF (sometimes called *Courts of Conscience*), were local tribunals, founded by Act of Parliament to facilitate the recovery of small debts from any inhabitant or trader in the district defined by the Act: they have been altogether superseded by the COUNTY COURTS.

REQUIEM (*Requies*, Lat., *rest*), the name of a mass sung in the Romish Church for the repose of the dead, beginning *Requiem æternam*, and in the Roman Catholic liturgy called *Missa pro Defunctis*.

REREDOS. [RETABLE.]

RESCUE, in Law ('rescous,' from the old French word *rescourser*, 'to recover'), is the unlawful and forcible setting at liberty a person or goods, in lawful custody. A rescue may be either a criminal offence or a civil injury, according to the circumstances under which it is effected. The character of the criminal offence is determined by the character of the offence committed by the person rescued. If, for instance, a party has rescued a traitor or a felon, he has committed the offence of treason or felony; but as the treason or felony of the person rescued cannot be assumed to have been committed until after his conviction and judgment, it is not proper to arraign the rescuer for such offences until after judgment of the principal offender. But the rescuer may be indicted for a misdemeanor before such judgment. For a rescue from lawful custody is in all cases a misdemeanor. Several statutes have, however, varied the character of this offence, and the punishment.

Previously to the abolition of arrest on mesne process, if a prisoner in custody of the sheriff on mesne process was rescued, the sheriff might make a return to that effect, which freed him from further responsibility; the rescuers being liable to an attachment for a contempt, and also to an action at suit of the plaintiff.

Where a party is arrested, or goods are taken upon a final process, the sheriff cannot return that there has been a rescue, and either he or the jailer is in all cases, except where the rescue is effected by the king's enemies, answerable in an action by the plaintiff. This liability is concurrent with the liability of the rescuers themselves, the plaintiff having the option to sue either the rescuers or the sheriff.

(Com., *Dig.*, 'Rescous;' Hale, *P. C.*; Hawk., *P. C.*; Russell, *On Crimes*; Matthews, *On Criminal Law*.)

RESERVOIRS. In engineering works the word *reservoir* is understood generally to apply to the large collections of water which are made for the purpose of feeding canals, or of supplying the head waters of a mill, or of supplying the water required for municipal services. The water, in almost all these cases, is obtained by storing the excess of the rain-fall (which would otherwise pass off from the surface of the land, by the streams or rivers, during the rainy seasons) in artificial ponds, provided with sluices, feeders, or main pipes, to conduct the water to the places where it is required. Under these circumstances the dimensions of reservoirs, and the modes of their construction, must admit of every imaginable variation; but the general principles connected with their formation may be briefly stated as follows.

The reservoirs for feeding canals, or inland navigation, may be made without much reference to the quality of the water to be stored in them; but those which are designed for the purpose of a town supply must be made in such places as to obviate any danger from the contamination of the water. It is customary that they should be formed, in either of these cases, if practicable, in the gorges of mountainous districts, where there might exist a large area of land having a natural fall towards the outlet of the gorge. Writers upon meteorology calculate that upon the average ⅓ of the total rain-fall of the whole year passes off by means of the superficial natural watercourses; that another ⅓ passes off by evaporation; and that the remaining ⅓ descends into the ground to feed the land springs and the wells. In mountainous districts, however, these proportions do not hold good; for, firstly, it happens that, as a general rule, the nucleus of mountain chains consists of dense impermeable rocks, which not only oppose the infiltration of water, but also from the steepness of their escarpments throw off the rain-fall in greater abundance than would be the case in more level districts. Secondly, on mountains the rain-fall is usually more abundant than it is on plains, and it is more evenly distributed over the year; so that the natural surface of the ground does not become so absorbent, nor does the evaporation from that surface take place with the same rapidity, as it would do in the low lands. It thus happens that the quantity of water, which may usually be calculated as being likely to find its way into a reservoir placed in a mountainous district, may be reckoned as being about one half of the total rain-fall; but the net quantity disposable will be often very inferior to the quantity thus originally impounded, because there must always be an active evaporation going on from the water surface, (which, moreover, will take place to the greatest extent when the water is most wanted) and there must always be a more or less active infiltration through the bed of the reservoir itself. As it will be necessary to discuss the effects of these conditions of evaporation and infiltration under the article WATER SUPPLY, on account of their influence upon gravitation water-works, it may suffice here to say that it is very rarely indeed that the engineer can depend upon commanding more than from ⅓ to ½ of the total quantity of the rain-fall of his drainage area; and that it is only exceptionally that he can attain the higher limit above quoted.

Another very important consideration will be found to affect the dimensions of reservoirs, which has only been cursorily noticed above, namely the distribution of the rain-fall over the year. In many cases it is known that rain does not fall for months together; and even in the Bagshot Heath district droughts of four and five months duration have taken place. A reservoir established in such a district must then contain; 1st, the total actual quantity required for the service it is intended to perform; and it is to be observed that during droughts the consumption of water must be nearly double that which would be required under normal circumstances, whilst the reservoir must be made large enough to supply the *largest* consumption, not the *average* one. 2nd, it must contain, in addition to this quantity, enough water to compensate for the evaporation and infiltration, and to secure the water from injurious chemical changes. In fact the water of large lakes even, unless constantly kept in motion by streams passing through them, is liable to become vapid and deficient in aeration; whilst pond waters, in dry, hot weather, become positively nauseous, unless their volume should be very great indeed; and vegetation, and the lower forms of animal life, develop themselves with singular activity under the same circumstances. Of course this latter consideration would not materially affect canal reservoirs, but it is an all important one in the case of gravitation water-works, and the singular story of the introduction of the *anacharis alsinastrum* into our canals, proves that it is expedient to watch the growth of aquatic plants even in canal reservoirs.

In all descriptions of reservoirs it is important that precautions should be taken to prevent the accumulation of alluvial matters of a nature to fill them up; and, in the case of water-works reservoirs, this is essentially necessary because the waters standing for a long time over them must contract impurities from those matters. The nature of the surface of the drainage area will regulate the nature of the precautions to be taken; for, if the soil should be one easily moved by the surface rills, it will be necessary to form depositing pits on the courses of the feeding streams; on hard limestone, slate, or plutonic formations, it may often only be necessary to prevent large boulders from being carried into the reservoir; and on peaty uplands, it will usually be found that the surface of the country will itself suffice to prevent the transport of much alluvial matter. The water obtained from peaty lands, it is to be observed, is not fit for the purposes of a municipal supply; and hitherto no satisfactory mode of removing the qualities communicated to the water by the peat has been discovered. For canal purposes peaty water is as good as any other, inasmuch as its colour and taste are of no importance for purposes of navigation; but either for irrigation, or for town supplies, such waters are inadmissible.

In selecting the position for a reservoir the most important conditions to be considered are, firstly, the nature of the bed; and secondly, the position of the retaining wall. The bed must not only, as said before, be of a nature not to communicate impurities to the water, but it must be for all practical purposes, impermeable. The value of a reservoir, in fact, depends on its power of storing, that is to say, of its holding water; but when the strata of which its bed is composed are so much fissured, or are of so permeable a nature as to allow the water to escape, it becomes necessary both to increase the original volume of the water stored, and to guard against the danger of the water's finding its way under the seat of the dam. The construction of the latter is, however, the most important part of the works required for the formation of a reservoir, for the depth of water against its face frequently is not less than 40, or even 70 feet, so that the pressure calculated to turn the reservoir over upon its outer edge, or to thrust it forward horizontally, is enormous; and the difficulties of construction increase precisely in proportion to the height and the length of the dam. Its position must therefore be selected in some portion of the gorge to be converted into a reservoir where the sides approach one another so as to contract the opening of the valley; the foot of the dam must be carried down far enough below the surface of the ground or of any subjacent permeable strata, to prevent the lateral passage of the water; its thickness must be made superior to that required to resist any possible dynamical effort it may be exposed to; the materials of which it is composed must be able to resist the passage of water; it must be made high enough to prevent waves, by whatever cause produced, from washing over its crown; and finally the overflows, bye washes, waste weirs and accessory structures (such as the sluices, draw-off pipes, &c.) must be made perfectly water tight, unless in the parts especially designed for the passage of the water. To secure the condition of the impermeability of the seat of a dam it is often necessary to carry the foundations as far below the surface as the dam itself rises, and instances of foundations fifty feet deep are by no means rare. Telford even recommended that when the strata on which a reservoir had to be formed were of a porous nature, the whole of the valley should be puddled; so great an importance did he attach to the necessity for opposing this dangerous action.

The dams of reservoirs are either formed of earthwork, or of masonry, or of a mixed system of earthwork and masonry. Local circumstances must guide the engineer in his selection of the precise nature of the materials he will employ; but the result of careful observations on the movements of large works of this description has led to the general recognition of the following practical rules for the thicknesses to be given. When masonry dams are used, it is found to be necessary to make the thickness of the wall, x, equal to the following proportions of the height of the dam above the surface of the bottom of the reservoir near its foot:

at the top . $x = h \times 0{\cdot}30$
in the middle $x = h \times 0{\cdot}50$
at the bottom $x = h \times 0{\cdot}70$

When earthwork is used the dam should be made from 15 to 16 feet wide at the top, with slopes of at least 1½ to 1 towards the water, and of 2½ to 1 on the dry side; the water side must be protected against the abrasion of the waves by stone pitching, and below the line of agitation its face must be carefully puddled. A wide puddle trench, or a thick wall of hydraulic masonry, should be carried up in the heart of the bank, and every precaution must be taken to resist the passage of the water through the various layers of the body of the work. As a general rule the materials of the bank should be deposited in layers of from 6 to 9 inches in thickness, and well and carefully rammed; care being taken to prevent anything like a perfect horizontality of bedding, by making occasional steps in the layers of earth. Similar precautions must be taken in the formation of masonry dams, and the layers, or horizontal beds must be stepped. It is also to be observed that there is a tendency in all long straight dams, of earth, or of masonry, exposed to the constant action of a great weight of water to assume in time the form of a catenary curve; and in order to resist this tendency it is customary to make earthwork dams segments of large circles in plan, with their convex side towards the water; and in masonry dams, it is usual to form strong counterforts on the down side, even when the same segmental horizontal outline, and the before-quoted thicknesses have been adopted. The usual rule is, it may here be added, to make the top of the dam about 5 feet above the maximum water level, in order to resist the action of the waves in the reservoir; a precaution which was proved, by the accident to the dam of the Croton reservoir, to be by no means exaggerated.

One of the most important accessory works of a reservoir is the bye wash, or waste weir; a portion of the enclosure over which any water is allowed to pass after the reservoir itself is filled to its maximum water line. The length of the bye wash must be made sufficient to carry off in a thin stream, the surplus products of the most violent storms, or of the most continuous winter's rains; and it must be made in such wise that the water flowing over it should not affect the stability of the dam, either by the cataract of the falling water, or by the velocity of the stream flowing from the foot of the bye wash. For the service of canals, or of town distribution, the water is drawn off by a series of sluice-gates, provided with the necessary contrivances to regulate the velocity of flow in the distributing channels; and it may be stated that, for a town distribution, the variable head upon the main pipes which is usually admitted, does not exceed 13 feet; and that in all cases it is desirable that the efflux of the water through the feeders, or the mains, should take place with as great regularity as it is possible to attain.

Some idea of the importance of the reservoirs formed for the supply of canals and town distributions may be derived from the following notes upon some of the most remarkable works of this description. Thus the Fountain Reservoir of the Croton aqueduct covers 400 acres, and has a depth at the dam of 38 feet: the Manchester Corporation Waterworks cover an area of above 408 acres, and have an average depth of 35 feet 6 inches, or they have a storeage capacity of 584,866,716 cubic feet; the Liverpool reservoirs have a storeage capacity of about 3,156,000,000 gallons; the Yan Yean reservoirs in Victoria, have an area of 1303 acres, and a storeage capacity of 6,400,000,000 gallons. The Canal du Midi, of France, has at Gros Bois, a reservoir of 300,510,000 cubic feet capacity, with a head of water at the dam of 69 feet 6 inches; the reservoir of the Nantes to Brest canal has a capacity of about 262,395,000 cubic feet, and a head of 38 feet; the reservoir of St. Fériol, on the canal du Midi, has a capacity of 223,090,000 cubic feet, and a head of 105 feet. The Birmingham canal has a reservoir of 80 acres area, with a depth of 45 feet at the head; the reservoir of the Union canal of Philadelphia, is not less than 780 acres in area, by an extreme depth of 40 feet, and it has a capacity of 572,000,000 cubic feet; on the Rideau canal of Canada, there is a dam 70 feet high; the Turton and Entwystle reservoir, in Lancashire, is of 100,000,000 cubic feet in capacity, &c. In England, it seems that the usual ratio of the storeage capacity to the area of gathering ground is from 30 to 40 thousand cubic feet per acre; and it is found practically that the maximum quantity stored never exceeds 15 inches over the area of the gathering grounds, in the most favourably inclined and impermeable districts; nor does it ever exceed 12 inches in flat retentive ones. The cost of forming large reservoirs has rarely, if ever, fallen short of 450*l.* to 500*l.* per million cubic feet of the storeage capacity, leaving out of account the accessory works, or the purchase of the land. A very important element in the cost of all such works is to be found in the compensation to be given to the parties who were formerly entitled to the water privileges existing in the district; but it is not possible to discover any general rule applicable to the countless variety of cases of this description. Some remarks on the subject will be found under WATER MILLS.

There is an important distinction to be made between the various kinds of reservoirs used upon town distributions, which may be mentioned here, though the discussion of the principles of their construction must be referred to WATER SUPPLY. The distinction in question is the one between the open storeage reservoirs, and the covered reservoirs, from whence the waters are distributed, generally after filtration. The latter are extremely costly structures, and are, therefore, rarely made larger than would be required for a four or a seven days' supply at the maximum; whilst the storeage reservoirs are made large enough to hold a quantity equal, when the rain-fall is about 60 inches per annum, to about 120 days' consumption; when it is about 48 inches, to about 140 days' consumption; and when it is about 22 inches (which is the case in the eastern parts of England), to about 200 days' consumption.

It may be interesting, archæologically, to add that some of the most extraordinary mountain reservoirs in Europe are those which were constructed by the Moors of Spain; that the Egyptians under the Pharaohs had executed some wonderful works for the purpose of storing the inundation waters of the Nile; that the native rulers and the Mohammedan conquerors of India vied with one another in the construction of the colossal tanks of that country; and that even the Aztecs had adopted a peculiar system of aguadas, or underground reservoirs, for the purpose of storing the copious but partial rains of their country. The Moors and the Egyptians seem to have used the water they stored principally for the purpose of irrigation. The Greeks and the Romans supplied their towns with water from springs and rivers, and very rarely attempted to execute irrigation works, so that there are no authentic records of the formation of artificial storeage reservoirs by either of those nations. One of the most ancient works of this description whose history can be identified in modern times is the reservoir of St. Fériol, on the Canal du Midi; and nearly contemporaneously with it the system of catchwater ponds, which supply partially the fountains of Versailles, was executed by the orders of Louis XIV.

RESIDUAL, an expression which gives the remainder of a subtraction, as $a - b$.

RESIDUARY LEGATEE. [LEGATEE.]

RESIGNATION. [BENEFICE.]

RESIN. [TURPENTINE.]

RESINEIN. [TURPENTINE.]

RESINS, a large class of substances, existing chiefly in the vegetable kingdom, and of which common resin, rosin, or colophony, is the type. They are generally obtained by incising the bark of trees; *oleo-resin*, or a mixture of a volatile oil and resin, then exudes, and gradually hardens. It is possible that the resins do not exist as such in plants, but that they are produced by the oxidation of essential oils.

The chief properties of resins are: insolubility in water; non-volatility; solubility in alcohol, ether, benzole, essential oils, and by the aid of heat in fixed oils; are insulators of electricity; become negatively electric by friction; fuse when heated; and, in contact with air, burn with a bright, but very smoky, flame.

But little is known of the constitution of resins. Constantly, but slowly, absorbing oxygen, with or without evolution of carbonic acid or water, or both, it is almost impossible to obtain them in anything like a definite state. Again, with one or two exceptions, they do not crystallise, and this greatly increases the difficulty of determining their individuality. Some—such as santonin, eugenin, gamboge, cubebin, myrrh, and chrysophanic acid—seem to be produced by the simple replacement of a number of equivalents of oxygen for an equal number of equivalents of the hydrogen in the essential oil. Others, for example, styracin, anime, red resin of rhubarb, mastic, amber, elemi, and aloetin; not only take up oxygen in the place of hydrogen, but also assimilate water. Many are probably mere oxides of the volatile oils; some we know to be simply hydrates. As yet, the resins have not been artificially formed from the pure essential oils: could this be accomplished, an important insight into their constitution would, no doubt, be obtained.

The solutions of several of the resins in alcohol redden litmus-paper, indicating that they are acid bodies. Such resins combine with alkalies to form soaps, differing but little from ordinary soaps. Common rosin, for example, contains *sylvic acid*, which crystallises in prisms; *pimaric acid*, which is obscurely crystalline; and *pinic acid*, which is amorphous. These acids, as well as many other solid and liquid bodies existing in or obtained from resins, will be found described somewhat more in detail under TURPENTINE.

Many of the resins are used in medicine; several have considerable commercial value, being used for the preparation of varnishes by dissolving in turpentine, wood naphtha, or spirit of wine.

The more important resins are treated of in this division of the ENGLISH CYCLOPÆDIA under their respective names, or in the NATURAL HISTORY DIVISION either individually or under the name of the plant from which they are obtained.

Gum-resins, as the name implies, are mixtures of GUM and resin.

For *Icicane*, and resin of icica, see TURPENTINE.

The resins of commerce are in some cases natural exudations, while others are obtained from vegetable compounds by the action of alcohol. They are for the most part brittle, tasteless or insipid, and fusible at a moderate heat; they seldom have any smell; they generally burn with a strong yellow flame, emitting a large quantity of smoke.

The ordinary resin of the shops is *colophony*, obtained as a residue after the distillation of oil or spirit of turpentine from common turpentine. The *black* resin is the cooled brittle mass in the state in which it leaves the still; whereas the yellow resin is the black modified by the action of water. *Resin-oil* is made in London, Liverpool, Bristol, Hull, and Glasgow, as an ingredient in lubricating grease for railway axles and for the bearings of heavy machinery. It is also used in France as an ingredient in printers' ink, thereby giving the unpleasant odour which is often observable in newly-printed French newspapers. Most of the common resin comes from North America, to the extent of 20,000 tons or more annually. *Resin-gas* is largely made in America; but in England it does not successfully compete with coal-gas. The chief uses of the various resins in England are for varnish, lacquer, sealing-wax, and dyeing.

RESISTANCE is a power by which motion, or a tendency to motion, in any body is impeded or prevented. When a weight or pressure acts upon a beam or bar in any direction, the tenacity by which the particles of such material oppose that action constitutes a resistance of one kind. [Materials, Strength of.] Again, when a body is made to move on another, the inequalities of the surfaces of both create a resistance of a different kind. [Friction.] When a body moves in a fluid, the inertia of the fluid particles displaced by it produces a third kind of resistance.

This last branch of the subject of resistances has already been in part considered under Hydrodynamics. In that article there is given a general expression for the measure of the resistance made by a fluid against a plane surface which is either perpendicular or inclined to the direction of the motion, together with a few results of experiments on the resistances experienced by bodies of various forms and lengths in moving through water. The relations between spaces and times in the vertical ascent and descent of bodies when acted on by gravity and resisted by a fluid, are given in the article Projectiles, Theory of; and, for the pressure against a cannon-ball moving in air, see the article Gunnery.

In investigating the resistances of fluids against bodies moving in them, it is customary in elementary writings, for the sake of simplicity, to consider the particles of fluid as unconnected with each other by contact or by any law of attraction, so that, when struck, their reactions may be considered as taking place perpendicularly to the striking surface of the moving body, whatever be the position of this surface with respect to the direction of the body's motion, and after the impact their action is supposed to cease. Such are called discontinuous fluids, and in these the motion produced in the particles by the collision is the measure of the resistance. Newton shows ('Principia,' lib. ii., prop. 35) what would be the resistance experienced by a cylinder moving in the direction of its axis in a discontinuous fluid; the cylinder and particles of fluid being elastic, so that the latter on being struck are reflected back with a velocity double the velocity of the cylinder; and he explains that, if the particles of fluid are not reflected, but are moved forward by the cylinder with a velocity equal to its own, the resistance is but half the former. But this hypothesis is far from being conformable to the constitution of fluid bodies in nature, the particles of these being connected by mutual actions. The elastic fluids, as air, at any place in the atmosphere are always in a state of compression from the weight of the column vertically above that place; and the particles of non-elastic fluids, as water, exert in every direction pressures which depend upon the distances of the particles below the surfaces of the fluid in the vessel, river, or ocean. In passing through a fluid of this kind (called a continuous fluid) a body strikes only the fluid particles which are nearest to it; these strike those beyond, and so on; and Newton proves (lib. ii., prop. 35, schol.) that in this case the resistance to a cylinder is only half the last-mentioned resistance, or one-fourth of the first.

In all these resistances however it is supposed that the particles on being struck are repelled perpendicularly to the front of the moving body; but, in fact, the particles of the fluid are in part repelled from the front in oblique directions, and, on account of the compressed state of the surrounding fluid, these particles not being able immediately to escape laterally, there is produced in front more or less condensation, and consequently an increase of resistance. The pressure of the fluid against the sides of the moving body creates also a resistance from friction; and when the velocity is very great, the fluid not falling towards the hinder part of the body so fast as the latter moves, the pressure there which would serve to counterbalance the resistance in front, is in part or wholly removed. On these accounts it is that military projectiles are subject to such vast retarding forces. It is computed that a 24-pounder ball experiences a resistance equal to 800 lbs. when its velocity is equal to 2000 feet per second. Like effects take place in the movements of boats and ships; when the velocity is great, the water accumulates in front, and flowing off from thence obliquely, it carries away some from the sides, and, causing the surface of that which is near the stern to be rather lower than the general level, it there produces a diminution of pressure, while there is an excess in front on account of the accumulation.

In order to find the pressure of a fluid against a body which is terminated in front by a curve surface, an expression must be obtained (by means of the equation of the surface) for the area of an elementary portion of that surface, and this must be multiplied by the cube of the sine of its inclination to the line of motion. The product being multiplied by $\frac{v^2D}{2g}$ [Hydrodynamics], and the whole integrated between the proper limits, the result will express the required resistance.

Again, in investigating the motion of a body on an inclined plane when resisted by friction and the pressure of the atmosphere, the general equation of motion $\frac{d^2s}{dt^2}=g-a\frac{ds^2}{dt^2}$ may be employed. Here s is the space described in the time t, $\frac{ds}{dt}$ is the velocity acquired in the same time, and $\frac{d^2s}{dt^2}$ is the differential expression for accelerative or retardative force. If the body were to descend vertically, g, the force of gravity (= 32·17 feet), would alone be the force producing the motion; and the equation, being integrated, would give the relation between the spaces described and the times of description when the body descends or ascends in a resisting medium. In the first of these cases g should be positive, and in the second negative. In order to adapt the equation to the descent of a body on an inclined plane, let θ be the inclination of the plane to the horizon; then $g \sin. \theta$ would represent the accelerative force on the plane if there were no friction. But since friction is proportional to the pressure ($=g \cos. \theta$) on the plane, and is independent of the velocity, let h be put for the coefficient of friction and represent a fractional part of the pressure; then we shall have $hg \cos. \theta$ for the retardation produced by friction. a is the coefficient of the resistance due to the pressure of the atmosphere; it depends on the form and magnitude of the moving body, and not on its weight; and the resistance is supposed to be proportional to the square of the velocity. Thus the above equation becomes

$$\frac{d^2s}{dt^2}=g \sin \theta - hg \cos \theta - a\frac{ds^2}{dt^2};$$

or, since the two first terms of the second member are constant, representing them by A, it becomes $\frac{d^2s}{dt^2}=\text{A}-a\frac{ds^2}{dt^2}$. Integrating this equation by successive approximations, or otherwise, we obtain in terms of t the values of $\frac{ds}{dt}$ (the velocity) and of s (the distance on the plane), either when the body sets out from a state of rest, or when it sets out with any given initial velocity. From these values, by means of the data obtained from good experiments, the values of h and a might be found; and thus the effects of friction might be obtained separately from those which are due to the resistance of the air.

The formulæ which are now generally received as expressing the resistances to which waggons moving upon railways are exposed are as follows:—They are of two classes; the one normal, and the other accidental; the one susceptible of *à priori* calculation, the other depending upon the state of the road, the action of the wind, &c., or upon conditions of an essentially variable nature. Of the normal causes of resistance, there are three kinds: 1, the friction of the axles in the boxes; 2, the friction of the wheels upon the rails; and 3, the resistance of the air, supposed to be in a state of repose, to the advance of the train. The level of the surface of the roadway naturally affects the numerical calculations of the various conditions thus specified; but, as was before said (under Railway), the introduction of the expansion gear into locomotive machinery has so modified the powers of that class of engine, that the importance of the precise value of the resistances to be overcome has of late been materially diminished. With an engine whose powers can be increased at will, and almost instantaneously, variable resistances are really matters of very little moment. The formulæ for this class of resistance are extracted from Perdonnet's 'Traité Elémentaire des Chemins de Fer.'

Taking into account, firstly, the case of a waggon moving in plain and on a dead level, it is evident that the horizontal movement must produce a friction of the bearing surface of the axle-boxes upon the axles themselves, which will be proportional to the pressure (or to the weight of the carriage, minus that of the wheels and axles), and will vary with the state of the bearing surfaces, but independently of their own state. If, then, the pressure upon the axle-boxes be represented by P, and the coefficient of friction by f (it will, in fact, be regulated by the nature of the bearing surfaces, their smoothness, and the nature of the lubricating material), the friction of the boxes on the axles will be represented by fP. Then, calling R the radius of the wheels, and r the radius of the bearing of the axle, every revolution of the wheels will cause the waggon to advance a distance of $2\pi\text{R}$, and every point of the bearing a distance of $2\pi r$; so that whilst the waggon advances through a distance = 1, the bearings of the axles will have slid over a surface $\frac{2\pi r}{2\pi\text{R}}=\frac{r}{\text{R}}$. The value of the friction of the bearings will then be, for the same distance traversed, $f\text{P}\frac{r}{\text{R}}$.

The friction of the wheels against the rails is a friction of the kind known as a rolling friction, and as such it is generally considered to be proportional to the pressure, and variable according to the nature of the surfaces in contact, but independent of the area of those surfaces, and of the speed of the motion. Or, calling p the weight of the wheels and axles, the total pressure or weight will be $\text{P}+p$, and f' the coefficient of friction, the expression of this description of friction will then become $f'(\text{P}+p)$. Strictly speaking, the value of f' would depend on the size of the wheels; but as, practically, the wheels of railway carriages are of the same diameter, f' may be considered to be a constant quantity.

When a body moves in a discontinuous fluid in repose, the resistance it meets with is proportional to the square of the velocity; to the area of the section of the body moved, taken normally to the direction of the movement: it is less in proportion to the length of that body in the direction of the movement; and if two surfaces, covered one by the other, move in the same direction, the resistance of the covered face will be equal to a fraction of the face immediately exposed to the air; and the smaller the interval between the two faces, the less will be the fraction in question. If, then, Q be called the resistance of the air sought, A = the area of the exposed end, V = the velocity of motion, ϵ = a co-efficient depending upon the length of the train, and θ = a constant co-efficient to represent the resistance caused by the intervals, the resistance of the air will be represented by the formula—

$$Q = \theta \epsilon A V^2.$$

It thence follows that the sum of the calculable resistances to be overcome when a train moves in a straight line, on a level road, may be represented (calling the resistance T) by the formula,

$$T = f P \frac{r}{R} + f' (P + p) + \theta \epsilon A V^2.$$

When the train moves upon an incline forming with the horizon an angle a, the gravity of the train is decomposed into two portions, one of which is perpendicular to the plane of the rails, and the other acts in a direction parallel to that plane, and tends to draw the train downwards; so that in pulling a train up an incline, the locomotive must exercise a power, not only able to overcome the friction, but also to overcome this effort of gravity in the direction parallel to the surface of the incline. The latter force, as is well known, is equal to $(P + p) \sin a$; the pressure of the bearings of the boxes upon the axles is equal to $P \cos a$; and the pressure of the wheels normally to the rails is equal to $(P + p) \cos a$. The force, then, which the locomotive must exercise upon a waggon in order to allow the latter to retain the velocity it had at any particular moment, under the conditions supposed, must be

$$f P \cos a \frac{r}{R} + f' (P + p) \cos a + \theta \epsilon A V^2 + (P + p) \sin a.$$

As the inclines upon railways are generally such that we may consider $\cos a = 1$, and that $\sin a = \mathrm{tg}\, a$, we may consider that the force exercised may, practically, be represented by the formula,

$$f P \frac{r}{R} = f' (P + p) + \theta \epsilon A V^2 + (P + p)\, \mathrm{tg}\, a.$$

The resistances a waggon encounters on a curve are of a complicated nature, and in a railway waggon they become more than usually so, from the fact that the wheels are fixed on the axles. Calling a the half width of the way, and ρ the mean radius of the curve, if the centre of the waggon travel over a space = 1, the interior wheels will travel $\frac{\rho - a}{\rho}$, and the exterior wheels $\frac{\rho + a}{\rho}$; so that the slip of each of them will be $\frac{a}{\rho}$. Now the wheels exercise a pressure $= P + p$, and if we represent the co-efficient of friction by f'', the expression of the resistance created by the fixity of the wheels will become $f'' (P + p) \frac{a}{p}$ for every unity of distance. But there is another resistance developed on a curve from the two axles of a carriage being fixed to its frame; for whilst the centre of the carriage traverses a circle described by the radius O (the mean radius of the curve), the respective points of contact of the axles describe a circumference around the centre G of the rectangle formed by the points of contact of the wheels and of the rails. The radius corresponding to these points of contact is $GA = \sqrt{a^2 + b^2}$, b representing the half distance of the two axles, and a the half distance of the two points of contact of the wheels on the same axle. The slip of the wheels, whilst the waggon makes a revolution round O, becomes then $f'' (P + p)\, 2 \pi \sqrt{a^2 + b^2}$. In the same space of time, the distance traversed by the waggon $= 2 \pi \rho$; so that the resistance caused by the wheels being fixed on their axles, and by the parallelism of those axles themselves, is represented by the formula,

$$f'' (P + p) \frac{2 \pi \sqrt{a^2 + b^2}}{2 \pi \rho} = f'' (P + p) \frac{\sqrt{a^2 + b^2}}{\rho}.$$

There is a third force developed during the curvilinear movement of a waggon arising from the pressure of the rims of the wheels upon the outer rail, whose expression is $\frac{P + p}{g} \cdot \frac{V^2}{g}$; in which g represents the accelerating force of gravity, which is in our latitude $= 32\frac{1}{6}$ feet. This pressure gives rise to a friction, $f''' \frac{P + p}{g} \frac{V^2}{\rho}$, in which f''' represents the co-efficient of the friction created by the pressure of the rims of the wheels upon the inner surface of the outer rail. But in addition to this there is a friction exercised by the surface of the rim in its motion along the inner edge of the rails, and the resistance thus developed by the friction due to the centrifugal force, for every unity of the advance of the waggon, is $f''' \frac{P + p}{g} \frac{V^2}{\rho} \frac{\sqrt{2 R h + h^2}}{R}$; in which R = the radius of the inner edge of the rim of the wheel, and h = the depth of that rim. The additional resistance thus created by the passage of a train over a curve is, then, represented by—

$$f'' (P + p) \frac{\sqrt{a^2 + b^2}}{\rho} + f''' \frac{P + p}{g} \frac{\surd^2}{\rho} \frac{\sqrt{3 R h + h^2}}{R}.$$

The total effort which the locomotive must exercise in order to retain the velocity it previously had, must, during the unity of the distance traversed, be equal to the sum of the resistances above stated; and it is therefore represented by the formula

$$T = f P \frac{r}{R} + f' (P + p) + \theta \epsilon A V^2 + (P + p)\, \mathrm{tg}\, a + f'' (P + p) \frac{\sqrt{a^2 + b^2}}{\rho}$$
$$+ f''' \frac{P + p}{g} \frac{V^2}{\rho} \frac{\sqrt{2 R h + h^2}}{R}.$$

In Perdonnet's 'Traité Elémentaire,' in Wood's 'Treatise on Railways,' in the second edition of M. de Pambour's 'Traité des Machines Locomotives,' &c., the various experiments by which the values of the various co-efficients in the above formulæ have been ascertained, are discussed at length. It may suffice here to say that generally speaking the values assigned by Coulomb to the co-efficients f, f'', are considered still to apply, though they are evidently in excess of the actual values as they have been indicated by experiments on railway trains; for Mr. Wood found that the total resistance of waggons of the old model travelling, at small velocities, upon a level straight line, was 0·00475 $(P + p)$, and De Pambour found it to be only 0·0026 $(P + p)$. Messrs. Gouin and Lechatellier found, by direct experiment with Morin's dynamometre, that the resistance from this cause was, at speeds varying between 15 to 25 miles per hour, equal to 0·003 to 0·0045 $(P + p)$; at speeds between 25 and 38 miles, it was = 0·0045 to 0·0085 $(P + p)$; and for speeds between 50 and 60 miles, it was = 0·012 to 0·015 $(P + p)$ On the average it may be taken that these resistances amount to 0·004 $(P + p)$.

De Pambour gives the value of $\theta = 0{\cdot}004823$, and that of $\epsilon = 1{\cdot}17$ for a cubical body, = 1·07 for a train of five carriages, = 1·05 for a train of fifteen carriages, and = 1·04 for a train of twenty-five carriages; but the learned author seems to consider the truest value of ϵ to be = 1·13. It is generally considered that the value of $f'' = 0{\cdot}16$; the value of f''' has not been ascertained by direct experiment, but it is known to be considerably greater than f''.

The practical conclusions drawn from the examination of these formulæ are: 1. The resistance is diminished by diminishing the diameter of the axles, and increasing that of the wheels. 2. It is desirable to diminish the weight of the carriages as far as may be consistent with safety. 3. The resistance in traversing a curve is increased in proportion as the radius is decreased. 4. The useful effect of locomotives is materially affected by their rate of motion, and economically there are serious objections to high rates of speed.

The experiments of Messrs. Gouin and Chatellier show also that a great portion of the resistance of a train arises from the frictions produced by the frame of the engine, and the frictions of its machinery. They found that, in fact, when the resistance of the whole train was equal to 0·0105 per ton, that of the carriages alone was 0·00625; that created by the frictions of the machinery alone, without reference to the load, was 0·0025; and the resistance created in the machinery by the pressure of the steam, was 0·00175. The speed in this case was about 28 miles per hour, and the experiments were tried on an incline of 1 in 125; the weight of the train was 60 tons, and the weather quite calm. Finally, it may be stated that it is usually considered that taking into account both the variable and the constant resistances to be encountered on railways the force required to ensure the traction at speeds of 20 miles an hour is equal to $\frac{1}{200}$ th of the load; and that if the speed should exceed 30 miles an hour it becomes $\frac{1}{100}$th of the quantity.

The method of finding the resistance which an engine opposes to the effort made by the steam to put it in motion, is as follows:—Multiply the area of one of the two equal pistons in square inches by the pressure of the steam on a square inch of the piston in each cylinder, when that pressure is just sufficient to cause the engine to move; the product is the pressure on each piston. Then, since the piston makes two strokes while the wheel of the engine turns once round, the velocity of the piston is to that of the engine as twice the length of the stroke is to the circumference of the wheel; and, the resistances being inversely proportional to the velocities, we have—

circumf. of wheel : twice the length of the stroke : : pressure on both pistons : the resistance, or inertia, of the engine.

But the resistance increases with the load which the engine has to draw; and, in order to determine it when attached to a train, the above proportion may be used; but the pressure on the pistons, instead of being found as before, must be taken when the engine and train are observed to have a uniform motion. Then the fourth term of the proportion being diminished by the known resistance of the train, will give the resistance of the engine alone.

From the experiments of Mr. Telford, the following values of the resistances experienced by loaded carriages on level roads have been determined. On a good pavement the resistance is $\frac{1}{70}$ of the weight of the carriage and load; on a broken surface of old flint, $\frac{1}{35}$; on gravel, $\frac{1}{13}$; and on a well-constructed railway, from $\frac{1}{300}$ to $\frac{1}{250}$.

By experiments made on the force (of traction) required to give motion to vessels on canals, it is found that the resistance varies nearly as the cube of the velocity; and this great deviation from the general law of resistances is probably caused by the reaction of the sides of the canal against the water displaced by the vessel. It deserves, however, to be mentioned, that when the velocity of the vessel is considerable, the resistance has been found to experience some diminution, perhaps on account of the water momentarily displaced, from its inability to escape laterally, becoming condensed, and thus giving superior buoyancy to the vessel, the immersed part being less, the pressure of the wate against the front will also be less.

Mr. Barlow observes that, with small velocities, the force of traction on canals is less than on railways; and when the velocity is equal to four miles per hour, the forces are equal. Beyond this velocity the advantage is in favour of the railway.

RESISTANCE OF MATERIALS. When solid bodies are exposed to the action of external forces, they are capable of resisting those forces by reason of the cohesion or of the elasticity they may possess, until their own powers are exceeded, when the particles of which the solid body in question is composed begin firstly to change their respective positions, and finally separate from one another. Within certain limits, the solid bodies in question are susceptible of resuming their original form after their particles have begun thus to change their positions (under conditions depending upon the nature of the external force) when the force is withdrawn; and it is according to the energy and the mode of exhibition of this power that bodies are ranged in the classes of elastic or non-elastic bodies, of highly elastic or perfectly elastic bodies. When the force is exercised in a direction parallel to the longitudinal axis of the body in a manner to pull or to extend it, the force is said to be one of *traction*, or extension; when it acts in the direction able to bind the particles of the body into closer contact, it is said to be an effort of *compression;* when it acts in a direction able to cause one part of the body to slide over the other,—or, in other words, to split it,—the force is said to produce an effort of *detrusion;* and when it acts so as to twist the particles or fibres of the material one over the other, the effort is said to be one of *torsion*. The terms *elastic*, *highly elastic*, and *non-elastic* bodies sufficiently explain themselves; but it may be desirable to add that bodies are said to be *perfectly elastic* when they resist, with equal energy, efforts of compression and of extension. The best wrought iron is an illustration of this property; but in the case of good cast iron, the resistance to compression is equal to nearly 6¼ times the resistance to extension: the former is nearly a perfectly elastic body, the latter is only imperfectly such. It was formerly considered that the compression of solid bodies took place equally, or, in the words of Hooke, that *ut tensio, sic vis;* but more recent experiments have shown that, beyond certain limits, the compression and extension take place with a greater degree of rapidity than would be proportional to the increase of the effort. The limits of equable resistance thus alluded to correspond with the range of the unimpaired elastic powers of the body; for if the effort should be such as to cause the body to compress or to extend with an accelerated velocity, the original dimensions and form will not be reassumed when the effort is withdrawn. Bodies so affected are said to have had their permanent elasticity interfered with; or their elasticity has been changed, so as to produce either a permanent elongation, contraction, or flexure, as the case may be.

There is a very important consideration which must always be borne in mind in determining the effort to be applied to any body, namely, that the length of time during which it is so applied has a material influence upon the resistance; or, in other words, bodies will resist instantaneous efforts of far greater value than they can resist permanently, without alteration in their elasticity. It therefore becomes a matter of necessary precaution (in all building or mechanical operations), to keep the forces to which the various materials are exposed considerably within the limits of what would be able to produce instantaneous changes of their natural elastic states; and this is the more necessary because the materials alluded to are, in practice, subject to shocks, jars, or accidental efforts, which may be of a serious nature.

Modulus of Elasticity.—If a prismatic, or cylindrical body of a given length, L, and an area A, be exposed to an effort of longitudinal traction in the direction of its axis P, it would extend under this action by a quantity we may call l; and if this quantity should be proportional to the total length, in such a manner as that $\frac{l}{L}$ should be a constant quantity, it may be represented by i, and will represent the elongation for every unit of length. Now, so long as this quantity does not exceed the limits of the perfect elasticity of the material, i increases proportionally to the load and the area, or to the ratio $\frac{P}{A}$; so that in fact $\frac{P}{Ai}$ is a constant quantity, which is called the *co-efficient*, or *modulus of elasticity*, and is usually expressed by E. If then, the transverse section were equal to the unity of surface, and the elongation i, for every unit of length, were equal to that unit of length, $A i = 1$, and $P = E$ would be the effort supported by the unity of surface, and able to produce for the unity of length an elastic elongation equal to that unity. The same remarks will apply to efforts of compression, and it is generally admitted that the co-efficient of elasticity has the same value in the two cases, although in certain granular bodies this law does not appear always to hold. As the relation $P = A E i$ becomes $P = E i$ and from thence $E = \frac{P}{i}$, when the load P is supported by every unity of the section A, it is easy to determine the value of E for every such unity of section, and thence to calculate the value of the load able to produce a given elongation of the body presenting that section, or to calculate the elongation produced by a given load.

Extension and compression.—A very great number of observations have been made for the purpose of ascertaining, experimentally, the laws which regulate the extension of solid bodies, the results of which may be briefly stated as follows. The load which is capable of producing rupture by extension, is directly proportional to the transverse section of the body considered; and the load has no reference to the length, provided the material be homogeneous, and the weight of the body be taken into account. The substances which have the highest co-efficient of elasticity, are those which resist rupture by extension in the most energetic manner; that is to say, they are the most tenacious. The temperature of the bodies considered must be taken into consideration; for the expansion produced by an increase of temperature in many substances acts in such a manner as to produce a longitudinal extension, whereas in others it produces a change in volume; and this remark may be extended also to the changes which follow upon any alteration in the molecular structure of a body; because, in the first place, every new crystalline arrangement is liable to produce some change in the volume of the substance, and in the second, the relative positions of the axes of the crystals may, and often do, singularly affect the powers of resistance to extension. In a great number of the materials used in the arts the resistances to extension and to compression are nearly equal; but there are cases (as for instance, building stones and cast iron) in which there are marked differences in these respective powers.

As a general rule, it is more important in the arts to know the limits of the resistance of the substances employed to efforts of compression, and it thus happens that the majority of the experiments, made upon the physical properties of those bodies, have been made with a view to the solution of that class of investigations. The law before stated, as applying to the resistance to extension, sensibly holds with respect to compression, and it is expressed by the formula $N = A R$, in which $N =$ the total effort exercised normally to the direction of the base, $A =$ the sectional area of the prism, and $R =$ the resistance for every unity of the section. When, however, the bodies pass certain lengths, compared with the dimensions of their sides, the resistances to compression cease to follow the ordinary law, and it becomes necessary to divide the theoretical results, obtained by the application of the tables of resistance, by a co-efficient varying with the proportionate length of the prism to the diameter of the polygon circumscribed upon its base. Thus, when the diameter of the polygon is in a lesser ration than 1 to the following tabular numbers, representing the height, the co-efficient becomes, in each case, as under:

Ratio 1 . . .	10	15	20	25	30	35	42	46	50
Co-efficient . .	1	1·2	1·6	2	2·8	4	6	8	10

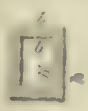
Again, the form of the body experimented upon, and the relative positions of its molecules, have an important influence on its resistance, for Vicat has shown ('Annales des Ponts et Chaussées,' 1833) that the resistance of a cylinder of stone to compression, in a direction at right angles to its bedding, is rather greater in proportion than that of the circumscribed square; a cylinder laid flat crushes under a weight which does not exceed $\frac{1}{3}$ of the one required to crush it when loaded on end; and the inscribed sphere will crush under $\frac{1}{4}$ of the load of the cylinder. Compound substances were found to crush more readily than homogeneous ones; that is to say, that cubes of stone built up of several pieces were found to crush more easily than monoliths did; but the general conditions of their resistance to compression were, after due allowance for this law, precisely analogous to those of solid bodies. In fact, in large masses of masonry, the resistance to efforts of compression is regulated by the resistance of their weakest parts, that is to say, by the resistance of the mortar used; and if it were required to calculate within safe limits the condition of the stability of a lofty pier, it would also be necessary to apply the co-efficient for the relative heights and bases just quoted. Vicat observes that in many cases loads, which for as much as 95 days were not able to produce any perceptible effect upon the bodies exposed to their compressive action, were able ultimately to destroy them; and he thence inferred that it was not safe to employ any materials, under efforts of permanent compression exceeding $\frac{2}{10}$ of the effort required to produce instantaneous rupture. In the case of substances possessing very imperfect elasticity a diminution of volume may frequently be produced by an effort of compression, which would not be recovered if that effort were withdrawn, even though the substance had not begun to disintegrate, nor its molecules had lost their cohesion. The clays and loams, so frequently met with in foundation works, are exposed to this peculiar action; and it requires to be taken seriously into account in building operations. Water is one of the imperfectly elastic bodies, but it resists compression with very great energy.

Temperature has a decided influence upon the powers of resistance of bodies to efforts of compression. For an increase of temperature, beyond the atmospheric average, diminishes in a gradually accelerating ratio the solidity of the bodies, whilst a decrease of temperature, below the freezing point, by affecting the powers of cohesion (or in common phrase by its rendering the bodies more brittle), causes the bodies to break up more rapidly. In materials obtained from stratified deposits, such as the decidedly laminated building stones, &c., Vicat found that the resistance to compression was much greater when the effort was applied in a direction perpendicular to the bedding, than when it was applied in a direction parallel to the beds; and in fibrous materials the resistance to efforts, either of extension or of compression, is the greatest when those efforts are applied in the direction of the fibres. In this last-named class of materials it is especially necessary to preserve them from flexure in their length; and thence also the necessity for observing the proportions before stated between the various conditions of base, height, and load. As it has been ascertained, theoretically and experimentally, that when the mass of a body is arranged in the form of a hollow body, the resistance is nearly doubled, (when the thickness of the cylinder is made about $\frac{3}{10}$ of the diameter,) it becomes an additional reason for using hollow columns of metal to support heavy loads, because, in the first place, the powers of resistance to compression are increased, and, in the second, there is less danger of flexure, when the diameter of the body is thus made as large as possible.

In the works of Tredgold, Hodgkinson, Tate, Barlow, Moseley, Willis, Whewell, Morin, Navier, Prony, Bresse, Claudel, Bourdais, Daguin, Jamin, &c., the various conditions of the resistance of solid bodies, and of the forms of greatest resistance, are discussed in great detail; and the reader is referred to them, should he require to examine any complicated problem of this description. It may suffice here to say that the condition most commonly occurring in practice is, when a rectangular beam is exposed to a load acting either longitudinally, or transversally, to its axis. In the former case the whole action is either of compression or of extension, as the case may be, and in addition to what has been before stated, it is only necessary to observe that it is essential, in order that the action should be uniform, that the load should be brought to bear evenly over the whole area. When beams are, however, exposed to efforts acting transversally to their axes, the laws of their resistance become more complicated, for the deflections produced cause some of the fibres to pass into a state of tension, whilst some of the others are compressed, and some of them remain in a neutral state, as long as the limits of elasticity of the extended or compressed fibres are not exceeded. The modes of loading solid bodies are usually considered to be classed under the following heads, and the formulæ for calculating their resistances have been deduced from the known laws of mechanics. 1. When one extremity of the beam is firmly embedded in masonry at one end and acted upon by a force, P, applied at the other; then, calling the lever of the beam L; the resistance to compression and extension, R; the moment of inertia of the beam at the point of its bedding, I; and the distance of the line of the neutral fibres from the most distant point of the section of the part fixed, n;

$$\mathrm{PL} = \frac{\mathrm{RI}}{n};$$

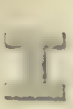
As in a regular prism of a rectangular section $n = \frac{h}{2}$ and the moment of inertia is $\mathrm{I} = \frac{bh^3}{6}$; this formula becomes $\mathrm{PL} = \frac{\mathrm{R}bh^2}{12}$, in which b = the transverse section of the prism perpendicular to the direction of the force P, and h = the section parallel to that direction. The deflection f would be represented by $f = \frac{4\mathrm{PL}^3}{\mathrm{E}bh^3}$; in which the new term E represents the modulus of elasticity.



2. If the solid be of the form shown, then calling b' the internal dimension in the same direction as b; and h' the internal dimension in the same direction as h; then,

$$\mathrm{PL} = \frac{\mathrm{R}(bh^3 - b'h'^3)}{6h};\ \text{and}$$

$$f = \frac{4\mathrm{PL}^3}{\mathrm{E}(bh^3 - b'h'^3)}$$ retaining the preceding notation.



3. In a beam of the section in the margin, calling b' the sum of the two deficiencies from the full section, and h their height, then also, $\mathrm{PL} = \frac{\mathrm{R}(bh^3 - b'h'^3)}{6h}$; and $f = \frac{4\mathrm{PL}}{\mathrm{E}(bh^3 - b'h'^3)}$.

4. The section being circular, and the radius $= r$; then the formulæ become $\mathrm{PL} = \frac{\mathrm{R}\pi r^3}{4}$, and $f = \frac{4\mathrm{PL}^3}{3\pi\mathrm{E}r^4}$; when the section is circular and hollow, calling r the external, and r' the internal radius, the formulæ become $\mathrm{PL} = \frac{\mathrm{R}\pi(r^4 - r'^4)}{4r}$; and $f = \frac{4\mathrm{PL}^3}{3\pi\mathrm{E}(r^4 - r'^4)}$.

5. If now the beam under consideration be carried at a point in its length, and be acted upon at its extremities by two forces which balance one another upon this point of support, the formula for a prismatic beam of a rectangular section becomes,—(calling m the leverage of the force acting at one end, and n the leverage of the force acting on the other; so that $m + n = \mathrm{L}$ the total length of the prism, and $p + q = \mathrm{P}$ the total load;) $\frac{pm + qn}{2} = \frac{\mathrm{R}bh^2}{6}$: and if $m = n = \frac{\mathrm{L}}{2}$, or if the point of support be in the middle of the length, then $\frac{\mathrm{PL}}{4} = \frac{\mathrm{R}bh^2}{6}$.

6. If the load applied to a prism, fixed at one of its extremities, instead of being applied at the other extremity, be evenly distributed over its length, then the load per unity of length being called p, the total load becomes $p\mathrm{L}$; and $\frac{\mathrm{L}}{2}$, the leverage of the total load $p\mathrm{L}$; the formulæ expressing the fundamental conditions of resistance become $\frac{p\mathrm{L}^2}{2} = \frac{\mathrm{RI}}{n}$; and $\frac{p\mathrm{L}^4}{8} = \mathrm{EI}f$, retaining the preceding notation for the old terms. From these formulæ, it appears that a beam loaded uniformly over its whole length, can resist an effort which would be double the one required to break it if applied only at the extremity the farthest removed from the section of rupture; and in order to produce equal deflections at the extremity, the load, distributed evenly over the whole length, should bear to the load applied solely at the extremity, the proportion of 8 : 3.

7. In the case of a beam resting upon two points of support at its extremities, if we suppose that the weight of the beam itself can be neglected, and that the weight, or load, P, be placed on the middle of its length; then as the effect upon the beam would be the same as if it had been fixed in the middle, and loaded at each end, by a weight $= \frac{\mathrm{P}}{2}$, the first set of formulæ would apply, excepting that P would be replaced by $\frac{\mathrm{P}}{2}$ and L by $\frac{\mathrm{L}}{2}$; so that for a rectangular prism the formulæ become $\frac{\mathrm{PL}}{4} = \frac{\mathrm{RI}}{n}$; and $f = \frac{\mathrm{PL}^3}{4\mathrm{E}bh^3}$. From this it appears that a beam supported at the extremities, and loaded in the middle, is able to support a load four times as great as a similar beam fixed at one end and loaded in the middle; and that the deflection would be sixteen times less than in the latter case. If the load, instead of being concentrated in the centre, were evenly distributed over the length, and the load per unity of length be called p, the total load would be $p\mathrm{L}$, and the formulæ would become $\frac{p\mathrm{L}^2}{8} = \frac{\mathrm{RI}}{n}$; and $f = \frac{5p\mathrm{L}^4}{384\,\mathrm{EI}}$.

It has been proved, both theoretically and practically, that a beam fastened at both ends will bear a load applied in the middle of its clear span, which would be double the one it would be able to support if it merely rested upon two points of support, and that the deflection in the former case would be four times less than it would be in the latter. As it generally happens that in building operations, beams and joists have bearings of only about one foot (which is insufficient to constitute an effective fixing of their extremities), it is essential to calculate their dimensions on the supposition that they are merely beams resting on two points of support.

Before closing these remarks on compression and extension, it may be desirable to add a few practical observations on the resistance of materials used in buildings. These are, 1st, that as the form of greatest resistance is almost always one in which the mass of the elements is concentrated at the top and bottom of a beam, leaving the portion about the neutral axis as light as possible, it follows that with plastic materials it is advisable to make the sections of the beam of a girder shape, that is to say with top and bottom flanges: the material must be distributed in those flanges according to its powers of resistance to efforts either of compression or of extension. [GIRDER.] 2nd, It is usually considered that a load acting with a shock, or able to produce sudden vibrations, acts in a manner far more injurious than if the same load were to act steadily; and in practice engineers have adopted the rule of never exposing a construction to a rolling weight greater than ⅙ of the permanent breaking weight. 3rd, It is usually considered that a deflection of $\frac{1}{400}$ of the span, is the maximum which should be tolerated; but that the safe deflection would only be $\frac{1}{2000}$ of the span. 4th, The resistance of cast iron to compression is, compared to its resistance to extension, as 6½ (nearly) to 1; on the contrary the resistance of wrought iron to compression is, compared to its resistance to extension, as 4 to 5.

Torsion.—With respect to the resistance to torsion it may be observed, that in a prismatic body submitted to such an action, the relation of the effort to the angle of torsion is constant for the same material, so long as the limits of elasticity are not exceeded. Calling this relation G; the effort Q; and the angle of torsion θ, for a rod of a given unity of length and of section; we have $\frac{\mathrm{Q}}{\theta} = \mathrm{G}$, which may be called the co-efficient of torsion. If then, we call P the force tending to twist a cylindrical or prismatic solid, in a plane normal to the axis; R, the radius of the leverage with which P acts; t, the angle of torsion; L, the length of the solid; and I, the moment of polar inertia; we have the moment of the force $\mathrm{P} = \mathrm{PR} = \frac{\mathrm{G}t}{\mathrm{L}}\mathrm{I}$; and from this we derive $t = \frac{\mathrm{PR} \times \mathrm{L}}{\mathrm{GI}}$. It is considered that the value of I becomes,

when the section is circular, $\mathrm{I} = \frac{\pi r^2}{2}$;

when the section is rectangular, $\mathrm{I} = \frac{b^3h^3}{3(b^2 + h^2)}$;

when the section is square, $I = \frac{q^4}{6}$,

calling *r* the radius of the solid cylinder; *b* and *h* the sides of the rectangle, and *q* the side of the square; when the section is annular, calling the external and internal radii respectively *r* and *r′*, the value becomes $I = \frac{\pi(r^4 - r'^4)}{2}$. In practice, the angle of torsion is usually made, $t = 0{\cdot}0005\frac{L}{n}$, in which *n* = the distance from the axis to the most distant fibre from itself. Mr. Bevan ('Philos. Trans.,' 1829) has given a table of the modulus of torsion for the different kinds of wood, which is appended; and he also states that for metals the modulus of torsion is equal to $\frac{1}{16}$ of the modulus of elasticity.

Detrusion.—The resistance to detrusion is at times called into action, in timber or iron construction; and therefore requires to be noticed. It has not been made the subject of any direct experiments, but it is supposed in fir timber to be equal to 592 lbs. per square inch in the direction of the force; in cast iron, 73,000 lbs.; and in wrought iron, from 45,000 to 53,000 lbs.

In Warr's 'Construction of Machinery,' a very useful comparative table of the various kinds of resistances of the principal classes of materials used in the arts is given as follows:—

Material.	Compression.	Tension.	Transverse.
Timber	1000	1900	85·1
Cast iron	1000	158	19·8
Stone	1000	100	10·0
Glass	1000	123	10·0

TABLE OF VARIOUS PROPERTIES OF MATERIALS.

Material.	Specific gravity.	Weight per cubic foot in lbs.	Tenacity in lbs.	Crushing force in lbs. per square inch.	Modulus of Elasticity.

RESOLUTION. [SOLUTION.] The resolution and solution of a question are, in common language, the same things. The word is also used as opposed to COMPOSITION.

RESOLUTION IN MUSIC. [DISCORD; HARMONY.]

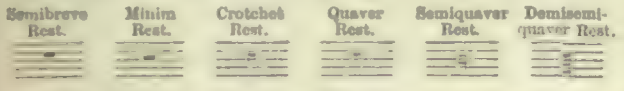
RESPIRATOR, or breath-warmer, an instrument invented and brought into use by Mr. Julius Jeffreys, for giving warmth to the air drawn into the lungs in breathing, and thereby enabling invalids to enjoy the benefits of exercise in the open air without injury or inconvenience.

The common practice of wrapping up the lower part of the face in a woollen covering warms the air inhaled through it very imperfectly, and in an unwholesome manner, by mixing with it a portion of the impure air exhaled from the lungs, and detained in its bulky folds. A woollen wrapper, being a non-conductor of heat, can act in no other way. In the respirator this disadvantage is avoided by causing the air discharged from the lungs to pass through several layers of very fine wire, fixed so near together that the breath passing through them is almost infinitely divided, its warmth being abstracted by the metal, which, being an excellent conductor of heat, freely imparts it to the fresh cold air drawn, or, as it were, filtered through it. The compactness of the instrument is such that there is no room for the lodgment of the impure air expelled from the lungs, and consequent contamination of that inhaled; and the condensation of moisture on the wires corrects the injurious dryness of the atmosphere in some northerly winds.

The means by which these objects are attained in the respirator display much ingenuity in contrivance, and no ordinary degree of skill in the execution. The inventor considers it necessary that about twenty layers of metal-work should be used, and, in order to make the instrument as light and compact as possible, each layer is required to be exceedingly thin. The apparatus usually consists of from eight to twelve frames of sheet-silver or other metal, about three inches and a half long, one inch and a half wide, and $\frac{1}{200}$th part of an inch thick; the metal of which is pierced away by machinery so as to leave merely a narrow frame containing six vertical bars of $\frac{1}{10}$th and five horizontal bars $\frac{1}{40}$th of an inch wide. On both sides of each of these frames a layer of wires an inch and a half long and $\frac{1}{100}$th of an inch thick is soldered, care being taken to connect each wire, not only with the top and bottom bars of the frame, but also with each of the five horizontal bars. The wires are laid about $\frac{1}{200}$th part of an inch apart, and are so numerous that a large respirator of high power contains 2000 feet of wire, divided into about 12,000 pieces, and soldered to the frames at more than 80,000 distinct points. The frames or lattices of wire-work are fixed parallel to each other, and kept a short distance apart by small studs of a substance which is a slow conductor of heat, so that the inner layer is always kept, as nearly as possible, at the temperature of the air expelled from the lungs, and each successive layer diminishes in warmth, till the outer one is nearly as cold as the external air. The curious and philosophical application of a non-conducting medium between the metallic screens is essential to the perfect action of the instrument, as without it the heat would be equally diffused, and no part of the metal-work could retain more than half the temperature of the breath. By this arrangement the air inhaled, finding each layer of wire warmer than the preceding, is gradually raised, in respirators of the highest power, to the greatest attainable temperature. The most powerful respirators have twenty four layers of wire-work, those of medium power sixteen, and the lowest power eight. The whole of the wire-work is bent into a curved form, and enclosed in a bordering or case of soft leather, which is made to fit closely to the face of the wearer, so as to prevent the entrance of air otherwise than through the metal-work, and to hold the latter in such a position that the lips do not come in contact with the wires. An outer covering of silk or other material is added, having an aperture in which is inserted a very thin plate of silver, perforated with minute holes, and to which a dark colour is imparted by a chemical operation, to serve as a screen to the wire-work, which it hides without impeding the passage of air as most textile fabrics would do. Recently however a very fine and open woollen fabric has been made use of in lieu of the perforated plate, to suit the wishes of some persons to whom the appearance of the instrument was an objection. The common or *oral* respirator covers the mouth only; but a variety called the *orinasal* respirator encloses the nostrils also. A piece of sponge attached to the lower edge of the instrument collects the moisture condensed from the breath, and it, as well as the metal-work and leather mounting, may be detached from the outer covering and cleaned when necessary.

RESPONDENTIA. [BOTTOMRY.]

REST, in music, a character denoting silence; a cessation of sound equal in duration to the note represented by the *rest*. As there are six musical characters called notes, so there are as many rests. Ex.:—



The breve rest, to be found in old music, is a short thick bar connecting two lines. Ex.:—

In separate vocal and instrumental parts, a character uniting three lines, and indicating a rest four bars in duration, is employed. Ex.:—

The following is the manner of directing a silence, or rest, of eleven bars, in any of the modern times or measures:—

RESTITUTION (in Law) *of lands*. Where a forcible entry or detainer of lands is on inquiry duly found, or after conviction under an indictment for a forcible entry, the court before whom the inquiry is made, shall cause *restitution* of the lands to be made to the party who has been turned out of possession. (Com., 'Dig.,' 'Forceable Entry,' D 5, &c.)

Restitution of goods. By 7 & 8 Geo. IV., c. 29, s. 57 (re-enacting a statute of Henry VIII.), if any person guilty of a felony or misdemeanor in stealing, converting, or receiving any property, shall be indicted for such offence by the owner or his executor, and convicted, the property shall be restored, and the court shall have power to award writs of restitution for the property, or order it to be restored in a summary manner. If it appears, however, that a valuable security has been *bonâ fide* paid or discharged by some person liable to pay it, or being a negotiable instrument has been *bonâ fide* taken or received by transfer or delivery by some person for a valuable consideration, without any reasonable ground to suspect that it had been stolen, &c., then the court shall not order the restitution of such security.

Restitution also formerly took place where the heir of one attainted of treason was relieved from the consequences of the attainder. (3 'Inst.' 'Restitution.')

RESTORATIONS, in Architecture, a term applied to drawings intended to show ancient buildings according to their original design, as made out from their existing remains, aided by such descriptions or hints as are to be obtained from classic authors, or from the representations of them on coins. The term restoration is, however, now more commonly applied to the actual *reconstruction* of an old building, where that reconstruction has for its object to reproduce the leading architectural features and ornamental details, so as to resemble as nearly as practicable those of the original building. In this sense of the term, a very large proportion of the Gothic churches in this country have been *restored* during the last few years; while many others are undergoing that process.

RESULTING USES. [USES.]

RESULTING TRUSTS. [TRUST AND TRUSTEE.]

RESUSCITATION (from *resuscito*, to arouse, to revive), the restoring to animation of persons apparently dead. Under this term, strictly speaking, should be considered the restoration of all cases of suspended animation, whether arising from disease or as a result of asphyxia; yet it is chiefly made use of to designate the recovery of persons from this latter condition. The symptoms, physiological conditions, and causes of asphyxia are fully described under that head; the treatment of it generally, and of its different varieties, was reserved for the present article. Although the suspension of all the vital actions of the system which takes place in asphyxia has originated from the temporary interruption of a single function, yet the derangement which has followed is of so complicated a nature, and extends to so great a number of important organs, that the mere re-establishment of the function primarily disturbed is not immediately followed by the restoration of the rest, and by the removal of all the mischief. The mere introduction of fresh air into the lungs cannot at once restore the action of the heart, or of the diaphragm, and of the other muscles which are concerned in respiration, because these muscles have lost either the whole or the greater part of their irritability, in consequence of having been supplied with venous instead of arterial blood. While the first and principal object is to bring the blood contained in the pulmonary vessels under the influence of atmospheric air, attention must at the same time be paid to the state of the circulation, and to the restoration of those powers by which that function, as well as respiration, is to be carried on. The first of these objects can be accomplished by the artificial inflation of the lungs; the second is to be attempted by the judicious application of stimulants to various parts of the body. The details of these processes have been already given in the article DROWNING. But asphyxia may also occur from the presence of foreign bodies in the larynx, which mechanically prevent the inflation of the lungs through the natural passage; in this case the operation of tracheotomy must be resorted to, and the pipe of the bellows must be introduced into the windpipe through the opening thus artificially made. In addition to the employment of artificial respiration, and the use of external and internal stimulants, many physicians have recommended blood-letting; but besides the doubtful advantage which sometimes may accrue from this practice, it is not always possible, and such is especially the case if the asphyxia is of long continuance. In general, the effects of blood-letting would be injurious, and it is now rarely had recourse to unless there are very unequivocal indications of great pressure on the brain. Whatever may be the means that we employ, they should be persevered in till the signs of death are no longer equivocal. Dr. Currie, in his 'Observations on Apparent Death,' recommends their being persisted in for at least six hours; the French writers mention the commencement of rigidity of the limbs as the only criterion of the hopelessness of continuing our efforts. The first signs of returning animation are slight convulsive twitchings in the muscles of respiration, which give rise to gaspings and sighings. By degrees these spontaneous efforts become more regular, and natural respiration is restored; and together with it the circulation returns. The first return to sensation is usually attended with great suffering, and the utmost attention is required to guard against the dangerous symptoms which sometimes show themselves at this period.

RETABLE, called most commonly by English architectural writers *Reredos*, the screen of wood or stone placed at the back of and above the altar in mediæval churches. Retables do not appear to have come were not usual till towards the end of the 13th century, the throne of the bishop having been till then usually placed at the end of the apse and behind the altar, so that anything rising above the altar would have obstructed the view of the congregation. At first the retable was merely a low screen, with a single row of sculptured figures placed in niches. But in the 15th century retables, whether of marble, stone, or wood, were made of large size, and adorned with a profusion of sculpture embodying the best sculptural art of the period. In Germany especially, they were often of extravagant height and costliness, reaching sometimes to the chancel roof, and covered with a multitude of small figures. In our own country they sometimes extended quite across the chancel. The leading events of the lives of the saint to whom the altar was dedicated were now often represented, the carved figures being coloured, and the ground gilt: characteristic examples may be seen at the South Kensington Museum, in one of French work with a large number of figures in high relief, of about 1500; and one of carved oak of the latter part of the 15th century of Flemish work, said to have been brought from the cathedral of St. Bavon, Ghent; while in the same collection is a still more remarkable triptych retable of the 15th century (No. 131) of German work, in which the life and martyrdom of St. Margaret are represented by numerous small figures arranged in compartments, which retain much of the original colour and gilding. Several other retables of mediæval date are in the same museum, and also one or two in marble of Italian renaissance work. Portable diptych and triptych retables were much used in the 16th century, of which some very beautiful specimens in ivory and in enamel are at South Kensington. Many of the churches of the continent retain fine examples of mediæval retables; and many fine reredoses, as the fixed retable was here called, may be seen, more or less mutilated, in our own Gothic churches, as at Durham, Gloucester, and Bristol cathedrals, St. Alban's Abbey Church, Henry VII.'s Chapel, Westminster Abbey, St. Saviour's, Southwark, &c.

RETAINER. [Executor; Serjeant-at-Law.]

RETAINING WALL is the term used for a wall erected to resist the thrust of a mass of earth, or of a volume of water stored in a reservoir. In consequence of the variable nature of the materials to be retained, as well as of the materials of which the walls themselves are composed, the practical application of the mechanical laws usually adopted for calculating the thicknesses of this class of works is more empirical than is usually the case in the ordinary operations of building. The following are, however, some of the generally received principles adopted by engineers in the construction of these walls.

Navier, who has applied the higher analysis to the investigation of the laws of the stability of buildings, gives a formula for the thickness of retaining walls, and a table of the weights of the materials commonly dealt with. The table is as follows, in English weights and dimensions:—

Material.		lbs.
Vegetable earth,	per yard, cube	2352
Clayey earth	,, ...	2688
Clay	,, ...	3192
Stiff earth, with pebbles	,, ...	3847
Marl	,, ...	2688
Mud	,, ...	2772
Fine dry sand	,, ...	2352
Wet do.	,, ...	3192
Argillaceous sand	,, ...	2940
Wet river sand	,, ...	3024
Rubble masonry	,, ...	3360
Ashlar	,, ...	4536
Brickwork	,, ...	3024

The formula for walls with two vertical faces is; calling

x, the thickness sought, in yards and decimals,
h, the height of the wall above its base, in yards,
P, the weight per yard cube of the wall,
P', the weight of the earth or other material,
θ, the angle that material, if left free, would form with the vertical line passing through the foot of the slope;

$$\text{then } x = 0{\cdot}59\, h \text{ tangent } \frac{\theta}{2}\sqrt{\frac{P'}{P}}$$

This formula would give thicknesses considerably less than those usually adopted in practice; for the general rule adopted by engineers is to make the thickness of retaining walls equal, on the average, to 1-3rd of the height, or 0·33 h. It must, however, be borne in mind, that there is no allowance made in the formula for the numerous disturbing causes which are frequently met with, such as the subsidence of the ground; nor does it take into account the cohesion of the earth, nor that of the masonry; it is, in fact, only founded upon the theoretical conditions of the equilibrium of the materials. It is even desirable in addition to the extra thickness thus given in practice to the walls, beyond that which is required by the strict application of theoretical laws, to give a batter to the external faces equal to 1-24th of the height. A greater batter than this would be objectionable, on account of its catching and retaining the falling rain; and it is desirable that the internal face of the wall should be formed in such a manner as not to hold up any water which might filter through the earth piled against it. In most cases, also, the resistance of retaining walls is increased by the introduction of counterforts; especially when the length of the embankment, or earthwork, to be retained is considerable.

Retaining walls used in situations where the earth at their backs is liable to become saturated with water by tidal action, or by the capillary attraction of the earth, must be established on the supposition that their backing becomes in fact a semi-fluid, denser than water, and which consequently has no angle of repose. Careful observations on the state of the walls in the French ports on the Channel, have shown that in many cases those walls have yielded when their mean thickness has even been as much as 0·41 : 1·00; and it therefore would appear that in such cases it is not safe to keep the ratio of the mean thickness below 0·45 or 0·50 to 1·00. In reservoir walls of masonry, the thickness should be made, practically, double that of ordinary earth-retaining walls, as indicated by theory; and especial care should be taken to ensure the adhesion of the wall to its foundations; for it is found that the expression of the resistance of these walls to overthrow is 0·41 h, while that of the resistance to longitudinal displacement is 0·50 h. The summit of the retaining wall of a reservoir should be made at least equal to 1-3rd or 1-4th of the head of water; and the effect of the surcharge of the masonry above the water-line may be neglected in estimating the statical resistance.

The reader who would desire to study the strict theory of this question would do well to examine the 'Mémoires' by Coulomb, Mayniel, and Prony, 'Sur la Poussée des Terres;' Navier's 'Leçons de la Mécanique;' Pasley's 'Course of Military Instruction;' Moseley's 'Engineering and Architecture;' but the most condensed and practical notice upon the subject is to be found in Carr's invaluable 'Synopsis of Practical Philosophy,' under the head 'Earth.' The following table of the angle formed by the natural slope of the materials enumerated may be found useful in applying Navier's formula, previously given, when it may be desired to calculate the resistance of a wall rather more closely than it is found necessary to do in practice:—

1. Fine dry sand forms with the vertical line a slope, having an angle of 69°; sometimes the angle is, however, = 55½, when the sand has been well rammed.			
2. Vegetable earth	do.	of	55½°
3. Loose shingle	do.	of	51°
4. Ordinary earth, well dried and pulverised forms an angle of			43° 10′
5. Rubble, small and rough	do.	of	37½°
6. Do. do. slightly moistened	do.	of	36°
7. Densest and most compact sand	do.	of	35°

From this table it appears that θ usually ranges between 35° and 70°; for water and for extremely fluid mud θ becomes = 9°.

RETINAPHTHA. [Turpentine.]

RETINOLE. [Turpentine.]

RETINYL. [Turpentine.]

RETISTERENE. A name given by Dumas to metanaphthaline.

RETORT, a chemical vessel in which distillation or decomposition is effected by the application of heat; for different purposes retorts are made of glass, earthenware, and metal.

Glass retorts are usually of the annexed form, with a receiver attached; they may be employed for the preparation of such products as do not require any extraordinary degree of cold for the condensation of their vapour: such a liquid is nitric acid. In this cut a represents the body of the retort, b the neck, and c is the receiver.

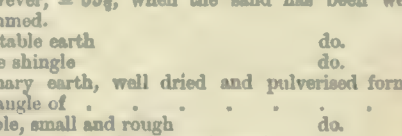

Fig. 1.

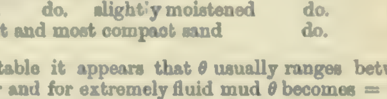

Fig. 2.

Fig. 3.

To prepare this acid, nitrate of potash is carefully conveyed by the neck into the body of the retort, and then sulphuric acid is added to it by means of the retort funnel *d*, which prevents any of this acid from remaining in the neck of the retort, and being washed down by and contaminating the nitric acid, as it condenses and passes into the receiver. In this case, when heat is applied to the retort, nitric acid and water rise together in vapour from the body of the retort, and are condensed in the neck; but when the product is more difficult of condensation, the neck of the retort is lengthened by placing an adapter *e* between it and the receiver, to both of which it is secured by a lute; it being understood that the wider end slips over the aperture of the retort, and the narrower one is admitted into the mouth of the receiver. In many cases condensation is accelerated by the use of a Liebig's condenser interposed between the retort and receiver. [CONDENSER.]

A stoppered retort *f* (*fig.* 4) is sometimes used instead of a plain one: these retorts are more expensive, but much more convenient than common ones; for both the dry and the liquid substances to be employed in the operation are passed into the body of the retort through the aperture, which is afterwards secured by a stopper, without having recourse to the retort funnel. Frequently also a quilted or tubulated receiver is used instead of the plain one above described: this is represented by *g*; the tube is inserted into a bottle *h*, and this, when ammonia or other very volatile or difficultly condensible products are distilled, dips into water, or the receiving bottle itself is immersed in water kept cold by ice or by a freezing mixture, as when hydrocyanic acid is distilled: *i* is the stand which supports the retort, and *k* is the lamp by which heat is applied to it.

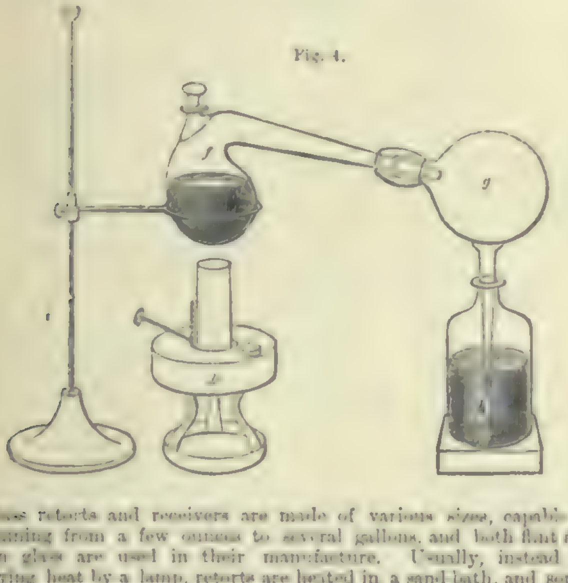

Fig. 4.

Glass retorts and receivers are made of various sizes, capable of containing from a few ounces to several gallons, and both flint and green glass are used in their manufacture. Usually, instead of applying heat by a lamp, retorts are heated in a sand-bath, and sometimes they are subjected to the direct action of the fire; but before this they are very commonly protected by a coating of lute. [LUTE.]

In general, when the application of the higher temperatures is required for distillation or decomposition, earthen retorts are employed. In preparing hydrofluoric acid, lead is used; and in concentrating sulphuric acid, platinum retorts are now largely employed, and would be universally so, were it not for their very high price.

In the destructive distillation of coal [GAS LIGHTING] iron retorts are used, and also, on the small scale, for obtaining oxygen from the peroxide of manganese, and various other chemical operations.

RETRENCHMENT, in Fortification, is a work constructed within another, in order to prolong the defence of the latter by impeding or preventing the formation of lodgments when the enemy has gained possession of it; or to afford protection to the defenders till they can retreat with safety or obtain a capitulation. In the latter instances the interior work is called by the French engineers a *reduit*.

Every principal work in permanent fortification is provided with its retrenchment or redout; and some of these, as the redout of the ravelin, and of the re-entering places of arms, are constructed at the same time as the work itself, while others, as the retrenchments within a bastion, are generally executed but a short time before they are wanted.

In 1552, when Metz was besieged by Charles V., the Duke of Guise, who commanded in the town, by constructing new ramparts within the old, as fast as the latter were destroyed by the besiegers, succeeded at length in compelling the emperor to raise the siege; and at the siege of Candia (1666–1669), the Venetians raised a rampart from one curtain to the next in rear of the gorge of the bastion St. Andrea, so that, long after that bastion was breached and taken, the town continued to hold out. Such prolonged defences are now rare, and the governor of a fortress is considered as having fulfilled his duty if he do not surrender till a breach has been made in the rampart of the enceinte; though if the bastion were retrenched, he might sustain an assault without any risk of being refused a capitulation, or of seeing the town given up to be plundered. In the event of the assailants gaining the top of the breach, the defendants would be able to retreat within the entrenchment, the fire from which might then be concentrated upon the enemy while confined within the comparatively narrow space between the faces of the bastion.

The kind of retrenchment proposed by Cormontaingne for the bastion of a fortress is a rampart or parapet extending across the interior of the work in a right line, or rather in the form of a tenaille. [X, FORTIFICATION.] Its extremities join the faces of the bastion at 20 or 30 yards in front of the shoulders, by which means the flank is left quite free, so that all its artillery can be employed in defence of the main ditch, and there is room between the retrenchment and the shoulder of the bastion for two guns, by which the interior of the ravelin and the ditch of its reduit might be defended, if necessary, even after the enemy had made a lodgment in the bastion.

As the retrenchment in this situation is liable to be enfiladed by a battery of the besiegers on the glacis before the collateral bastion, it is proposed that another should be formed in rear of the gorge of the bastion attacked; and as in this case there would be sufficient room, the retrenchment may be in the form of a front of fortification with a revetted scarp and counterscarp.

The ditch in front of a retrenchment, as at X in FORTIFICATION, is cut quite through the parapet of the bastion, in order to prevent the enemy, after the assault at the breach, from passing along the top of that parapet, and getting to the rear of the retrenchment. This opening of the parapet does not, however, go lower than the level of the cordon of the scarp revetment, in order to avoid diminishing the height of that scarp, and thus offering a facility to the enemy, should he attempt to escalade the work at that place.

Cormontaingne proposed to retrench small bastions by constructing within them cavaliers of the same form as the bastion itself, and having a command of 5 or 6 feet above it. The fire from this high parapet might give the work some advantages during the progress of the siege; but from its figure a cavalier appears to be less proper than a retrenchment in the form of a tenaille, for the defence of the terreplein at the top of the breach.

It is evident that full bastions like A [FORTIFICATION] must be more convenient for being retrenched than those which are of the kind called hollow, as B; since less earth is wanted to raise the retrenchment to the required level, and the scarps are covered by the opposite side of the ditch from the view of the enemy at the top of the breach. The most simple manner of retrenching a hollow bastion would be that of retaining the rampart on the interior side, where it is usually 10 or 12 feet high, by a wall, and cutting a deep ditch at the foot; then forming a traverse across the terreplein of the rampart on each face (at 20 or 30 yards from the salient angle of the bastion) with a ditch in front. The enemy, in gaining the top of the breach, would then find himself arrested by these obstacles, and exposed to the fire of the defenders, till ladders and the support of a large body of troops could be obtained. The bastions of Ciudad Rodrigo, Badajos, and St. Sebastian were retrenched in this manner when those fortresses were besieged by the British and their allies during the Peninsular war.

Vauban, having observed that the ravelin was sometimes abandoned by the defenders previously to an expected assault, on account of the difficulty of retreating across the main ditch under a fire from batteries on the glacis before the bastions, constructed, in the interior of that work, another, which might afford the defenders protection till the coming night would permit them to retire in safety. This work was at first only a wall, pierced with loop-holes for musketry and covering the steps at the gorge; but when Vauban increased the size of the ravelin, he made this redout, or retrenchment, to consist of a rampart and parapet similar to those of the ravelin itself, as at Neuf Brisac; and Cormontaingne subsequently enlarged the work, so as to render it a second ravelin, as at Y [FORTIFICATION]. This spacious retrenchment contributes much to the prolongation of the defence of the ravelin, since it is capable of containing a large body of troops; and each of its flanks carry three guns, whose fire might be directed against the counter-battery at the salient of the bastion, or might serve for the defence of the breach in the face of the latter, should the enemy attempt to make an assault before he has obtained possession of the reduit. But to take this last, it would be necessary to breach its faces either by artillery or by mining; and the passage of its ditches would be difficult under a close fire from the ramparts near the shoulders of the neighbouring bastions.

In order that the defenders might be able to retain possession of the extremities of the ravelin, near the main ditch, after the salient part may have been taken, retrenchments or coupures, as they are called, similar to the traverses, *t*, *t*, &c., are recommended to be formed across the terreplein of the ravelin. Behind these some of the defenders may retire, and keep up a fire against the enemy's lodgment near Z.

When Vauban had enlarged the re-entering places of arms, L [BASTION; FORTIFICATION], he retrenched the interior with stockades, which, by covering the steps leading from the ditches in their rear, protected the retreat of the defenders of the covered way; and Coehorn appears, about the same time, to have constructed brick walls, provided with loopholes, in the places of arms, at Bergen-op-Zoom, for the same purpose. But Cormontaingne, in order to render the defence of the places of arms more obstinate, and to secure more effectually the retreat of the defenders of the covered-way, constructed the redoubts, as w [FORTIFICATION], with parapets of earth 12 or 14 feet thick; and he revetted the sides of their ditches, in order to diminish the risk of a surprise: he also gave them flanks, which he made perpendicular to the covered way, that a fire of light artillery or musketry might be directed from them against the enemy while attempting to crown the salients of the ravelin. These redoubts moreover cover the shoulders of the bastions and the portions of the curtain which might be seen and breached by a fire directed between the flanks of the bastions and the tenailles; and their faces are directed so that they cannot be enfiladed. The crest of their parapet is about four feet higher than that of the glacis in their front.

The advanced works about a fortress are recommended to be retrenched with round towers of masonry, provided with upper and lower tiers of loopholes for musketry. These are called *safety redoubts;* and in Montalembert's 'Fortification Perpendiculaire,' such towers are constructed to carry artillery within the rampart of the enceinte.

For retrenchments in field fortification, see BLOCKHOUSE.

RETROGRADE, moving backwards, as opposed to DIRECT. In astronomy all motion from east to west is retrograde: thus the apparent motion of the heavens is retrograde, and the earth's diurnal motion, which causes it, is direct.

RETURN OF CATTLE, &c., is a term applied to the restoration of cattle, &c., distrained, to the party by whom they were distrained, after it has been ascertained that the distress was rightfully taken. The restoration of the cattle, &c., distrained to the owner is not called a return, but a replevin. [REPLEVIN.]

RETURN OF WRITS. When process [PROCESS] issues, the party to whom it is directed is commonly required to do a specified act, to certify the court in what manner the command has been executed, and at the same time to produce or *return* the process itself. Hence the whole answer to the process is called the return. [SHERIFF.]

REVELATION (removal of a covering, or discovery) signifies, in theology, a preternatural or extraordinary communication made by the Deity to men. The evidence of a revelation may be considered with reference to the party to whom it is first and immediately made; to those who have their knowledge of it immediately from him; and to those who possess only a recorded account of it. It should seem that in the case of the first recipient, the only evidence fully satisfactory must be something external to himself, or unequivocally presenting itself to the judgment of his senses. If it is asked why preternatural intervention is claimed in behalf of those to whom the revelation is delivered by the first receiver of it, and dispensed with in the case of those to whom only the record of it has descended, the answer is, that a miraculous fact is a subject for historical testimony; and if confirmed by that, conveys to future generations the same kind of security which it was intended to afford to those who witnessed it.

In saying that a miracle is the proper test of a revelation, we do not mean to exclude every other kind of proof. We mean only that a miracle is that one species of proof which cannot be spared. Many circumstances may be supposed to have place in a revelation, which would contribute greatly to confirm its reality, and which might with some minds have more influence in inducing acceptance than even the proof of miraculous agency.

We have spoken of a miracle as the test of a revelation, without attempting a definition, believing the common notion of it to be sufficiently accurate for our purpose. For the distinctive character of a miracle, and the possibility of proving it by evidence, the reader may consult the article MIRACLE in this work, and the authors referred to at the end of it. It is presumed that the purpose of the miraculous test is evident. A certain person is converted to the belief of certain truths by an appearance, undoubtedly miraculous, in the sky. The miracle is to him a proof that his conversion is from God. He teaches to others the truths which he has been made to believe: and in doing this performs miracles. These are a proof to them that he is commissioned by God to teach what he delivers; recorded and duly attested, they prove the same to those who have not witnessed them. All the parties, in accepting the test, would reason in the same manner, namely, that the laws of nature could be changed only by God, the author of them, or by his permission; and that he would not change them, or permit them to be changed for the purpose of establishing a falsehood.

To the question, "has a revelation been actually made?" the Christian believes that he has an answer in the possession of the Holy Scriptures, or the books of the Old and New Testament. An account of the contents of these books and an examination of the evidences of the Christian revelation form, of course, no part of the subject of this article: they are noticed under their respective headings. The proofs which we have insisted on as requisite to establish the reality of a revelation generally, must, if rightly assigned, be applicable to this particular one.

We insisted on the primary evidence of miraculous agency in the communication, with corroboration from the matter communicated, the miraculous agency to be so exhibited to the witnesses as to be capable of proof from testimony to others. Particular revelations may be supposed according to the circumstances under which they were given, and the nature of their contents, to admit various topics of evidence; almost all of which however will probably be found to resolve themselves into one or other of these two, though all inquirers may not agree in the classification. We should place for instance under the head of proof from preternatural manifestations, the fulfilment of prophecy in cases supposed to be beyond the reach of human foreknowledge or conjecture; the attested existence of persons exhibiting qualities, moral or intellectual, in kind or degree, not exemplified or to be expected in others of the human race; conduct of men, natural under the supposition that they were conscious and had proof of a divine commission, but otherwise unaccountable according to any known motives of human action.

The purpose and value of what may be called the corroborative evidence as distinguished from that founded on miraculous agency can hardly be overlooked. Between the highest degree of certainty with which a fact can be invested by evidence, and the faintest probability, there is room for every shade of assurance.

Now it is notorious both that different minds are differently affected by the same evidence, and that some minds seem peculiarly constituted by nature to admit the full force of one mode of proof, whilst they are comparatively insensible to another; so that it might happen that whilst to one inquirer the testimony which supported the story of the miraculous facts seemed so strong as to supersede the necessity of confirming his belief in the revelation by the evidence which the matter of it might supply, and which perhaps he might be little able to appreciate, another might rather feel that the miracles were so far proved as to complete the satisfaction which he had already derived from the other source.

The Christian revelation, which may be considered as forming one subject with the Jewish, from the wide field over which it is spread and the miscellaneous character of its contents, must necessarily supply, in large abundance, matter for examination in the way of evidence. An enumeration, which however does not pretend even to approach completeness, of the constituent parts of the body of evidence belonging to it, together with the proper mode of using them and estimating their joint force, may be found shortly but very clearly proposed in the first of Mr. Davison's 'Discourses on Prophecy.' Before we leave this part of the subject, we would observe, what seems sometimes to be overlooked, that an action may itself be a revelation. It would not be improper to say that the birth, death, and actions, even more than the discourses of Jesus Christ, were a revelation, of which the Apostles, who taught what are called the doctrines of Christianity, were only the interpreters. Of these doctrines it is not our business to treat, but we will select one as the subject of a few observations, merely with a view to illustrate the disposition of mind with which we must necessarily regard the pretensions and evidences of a professed revelation, according as we recognise, or not, a need which men have of extraordinary information on the subject of religion. The doctrine we select is that of the immortality of the soul and a future state of rewards and punishments. Without assuming the probability or improbability of this doctrine, we suppose it to be notorious that the immortality of the soul, or some kind of continued existence after bodily death, with liability to a state of happiness or suffering, has been very generally believed, in one shape or other, in all parts and at all periods of the world; and that this doctrine is distinctly delivered and prominently set forth in the New Testament. There is as little doubt that before the time of Christianity, either the notions commonly received of a future state were so irrational, or the belief of it so faint and unassured, that for the most part it had comparatively little effect on the moral feelings and conduct of men; and that on the other hand, wherever the Christian revelation has been published, this doctrine has not only been firmly received with little variation in the manner of understanding it, but has influenced the conduct of many, happily or not, in the most important respects, and regulated the whole course of their lives. It is plain that those who regarded the distinct and authoritative announcement of this doctrine to be among the things especially needed by mankind, and those who considered it to be either useless or mischievous, would be very differently impressed by the general body of evidence in favour of the revelation.

Among professed revelations which have been the ground of a national religion, it may be doubtful whether we should place the mythological systems of ancient Greece and Rome. They are indeed avowedly founded on traditional accounts of certain transactions between gods and men; but from the nature of the transactions, of the supernatural beings concerned in them, and the purposes of the interference, we may doubt whether the discoveries supposed to be made belong to the notion of a revelation according to our definition of the word, or the usual acceptation of it. The same for the most part may be said of the mythology of the Hindus and of the northern nations of Europe. But there can be no doubt that the religion of Mohammed, as taught in the Korán, professes to be founded on a revelation in the strict sense of the word, such as may be subjected to the same tests which we have supposed to be applicable to all revelations.

In passing from the Christian revelation itself to the written record of it, a new and important question is opened to us. The revelation may have been made to the persons who profess to have received it; but in recording it also, were they preternaturally assisted, or were they left to the use of their natural memories, and the guidance of their unassisted judgment? In other words, we are met by a question respecting what is called the inspiration of the books of Scripture, or, more properly, of the persons who wrote them. By this word we are to understand, not the preternatural infusion of revealed truths into the minds of the writers (which however would not be inconsistent with the original meaning of the word), but preternatural assistance in recording what had been so infused. This distinction should be observed. St. Paul, if we believe his own declaration, received immediately from God a message to men. He may be supposed to have delivered this message orally or in writing to others from memory; and in that case he would have been a deliverer and they receivers, in the strictest sense of the words, of a divine revelation; but the message, so delivered, would not in theological language have been an inspired message, that is, spoken or written under inspiration. It is beside our purpose to defend or impugn the doctrine of the inspiration of Scripture generally, or, out of the various theories which have been put forth, to advocate one in preference to the others. We only wish to do something towards clearing away certain fears and difficulties, which seem to beset and mislead many in the very outset of the inquiry, and to offer a few suggestions as to the principle on which the inquiry should be conducted, to those who are not very conversant with the subject.

In the case of most persons educated in the Christian faith, their first introduction to the Bible is accompanied by an assurance that it was dictated by God, and is *therefore* true; and this is told them at a time when its claims, as an authentic history, independently of its inspiration, neither are nor can be explained to them. This early impression, perhaps unavoidable, that the Scriptures are to be received as true, *only* because they are the Word of God, is probably retained for the most part without question, in spite of its inconsistency with the method and object of books which are given, almost as universally as the Bible, to all educated persons for the purpose of establishing their faith on rational grounds. Hence they are habituated from the very nursery to confound in their minds two questions essentially distinct, the divine origin of the Christian religion, and the divine origin of the scriptural records of it. All might easily remove this confusion by simply answering the question, what would be the natural course of our inquiries, and by what steps should we arrive at conviction of the divine origin of the Christian religion, if the volume of the New Testament were for the first time put into our hands for examination, at an age when we were capable of making it? It is obvious that we should not begin with assuming the inspiration of the writers; for that would be assuming the very point in debate, assuming that for which we had not as yet a shadow of evidence. But neither is it of their inspiration that it would be our first object to find evidence; for such evidence could not at first be obtained. If we ever came to the conclusion that they were inspired, it must be because either the very supposition of a revelation from God included in it the supposition of a revelation on the part of those who communicated it, or because all the writers themselves claimed inspiration, or some, whose claims we had already allowed, attributed it to the rest. In the former case we must *first* have believed that a revelation was made; in other words, that the origin of the religion was divine: in the other, if we assent to the claim of inspiration, we must *first* have admitted the credibility, the veracity of those who make it; that is, if we believe them to be inspired because they say so, we must have had reason for believing what they say, on other ground than that of their inspiration. It seems then that it would be our first object to establish, not the inspiration, but the credibility of the sacred writers apart from their inspiration. We should proceed from the establishment of their credibility, to inquire, in the second place, if they were inspired. The result, in short, to which we have actually come is this: the New Testament is put into our hands for examination, and we find that the claims of Jesus and his followers to a divine commission rest on the miracles which they are said to have performed. Our belief of the fact of the miracles depends on the credit we attach to the story of the witnesses. If that is substantially true, Jesus came from God. With the arguments by which the credibility of the gospel history is proved we have here no concern. It is plain that it is not proved by the inspiration of the authors. Some confusion seems to have arisen from a strange mistake respecting the kind of satisfaction which the inspiration of the sacred writers, when established, is capable of supplying. It does not confirm their veracity, it only implies their accuracy. It secures us from their mistakes, not from their falsehood. Now if it should be argued that without inspiration we can have no assurance that they were not mistaken, when they tell us that they saw a man dead on the cross, laid in his grave, and afterwards alive, it may be asked, how can they be secured from their liability to mistake, when they tell us that they are inspired? It is at least as likely that they should be mistaken in the one case as in the other. The obvious truth is, that if we cannot rely on their veracity when they vouch for miracles, we can trust none of their assertions, and admit none of their claims; and if they might be mistaken as to the fact of a miracle, they might be equally mistaken in their claim of inspiration for themselves or for others.

It is hardly necessary to observe that the various methods followed by writers on the evidences of the Christian religion are all in conformity with the view that has been taken of this subject. They endeavour to show the genuineness and authenticity of the books of the New Testament, the fidelity, disinterestedness, and integrity of the writers; to point out their means of information as human historians, and to confirm the accuracy of their accounts by comparison with other records. The question of inspiration forms no part of their inquiry. It is beside their object, which is to prove the divine origin of Christianity; and this is fully proved if their arguments are satisfactory.

It is not meant, of course, that all who are brought to a conviction of the truth of Christianity, arrive at it in the same manner. It is sufficient for our argument that it may be reached in the manner we have supposed. In short, on whatever support the believer himself may eventually feel that his faith habitually reposes, if he should ever be impelled by any motive to trace his conviction to a source from which it can be shown to others by reasoning that it may legitimately flow, he will find that he must rely, in the first instance, on the credibility of the sacred writers, however established, considered as uninspired historians. With this foundation laid, he may commence an inquiry into the proofs of their inspiration; and he may pursue it with a full assurance that to whatever result it may lead, the divine origin of his religion is already secured; that he has in possession a revelation from God, truths divinely communicated to men. We may seem to have taken unnecessary pains to establish a point too plain to be disputed. Our justification must be, that it does not seem to have been so plain to some even of those who have written on the subject, and are occasionally quoted as authorities, and who have been led, apparently by the confusion which we deprecate, into unwarrantable insinuations of infidelity against those who differ from them in opinion.

If the question should be asked, where, when the divine origin of the religion is supposed to be established on the credibility of the sacred writers, we should look for proof that the books which are the records of it were written under the security of inspiration? the natural answer would be that it must be looked for in the books themselves, from the claims, declarations, and intimations of the writers. When, for example, one of the evangelists has recorded a distinct promise made by their master to his Apostles, of a divine gift for the declared purpose of assisting the memory and enlightening the understanding, the inference seems to be unavoidable that those to whom the promise was given must have written with more than natural advantages. The argument founded on the necessity of inspiration to render the sacred books effectual for the purpose for which they were intended, ought not perhaps to be slighted. We have seen indeed that the supposition of the divine origin of the religion does not necessarily require the admission of inspiration; yet the peculiar character of the contents of the books, together with the service they were destined to perform, may raise a presumption in its favour. The direct testimony however from the writers themselves must be principally regarded. But when commencing the examination, whilst the evidence is yet to be found, we must be careful to estimate correctly the degree of authority which ought in this stage of the inquiry to be attributed to the words of Scripture. They are not yet proved to be the words of God. The declarations of the writers must be received and interpreted fairly and liberally, as the solemn declarations on a solemn subject, of honest and credible writers, ought to be received and interpreted. If the evidence which we seek to obtain from them cannot be obtained in this manner, it cannot be obtained at all. To search Scripture for proofs of its inspiration whilst at the same time we assume it to be inspired, is a proceeding so obviously absurd, that if experience did not teach us otherwise, any caution against it would seem to be unnecessary. But even when this strange error is not committed, declarations of the sacred writers, apparently bearing on this subject, may be and often are improperly summoned to the cause. When a writer professes to have received secret suggestions from the deity, that is, to be the subject of inspiration in one sense of the word, he is represented as claiming it in the other, as though the privilege of receiving communications necessarily implied the privilege of infallibility in recording them. This confusion has been noticed on another occasion.

That most popular argument for the inspiration of a particular book, founded on testimony borne to the purity and integrity of the canon of Scripture, may be soon disposed of. When it has been proved that a book forms part of what is called the canon, it may follow that it forms part of Scripture. This will not carry us far when the question to be decided is, what are the claims of Scripture to inspiration?

There is one mode of proof, besides those already mentioned, which ought perhaps to be noticed, as being much in favour with some theologians, namely, an appeal to what is called the tradition of the church. There are some advocates of inspiration, in the strictest sense and most unlimited application of the term, who allow, or rather contend, that the proof of it rests mainly, if not entirely, on the testimony of tradition. An examination of the value of this testimony would oblige us to enter more largely, than would here be expedient, on the important question of ecclesiastical tradition generally. We shall content ourselves with saying that, in this case at least, we greatly doubt, for many reasons, the sufficiency of the witness, and are not satisfied, even where it speaks to the purpose, that its words have always been rightly understood. However this may be, it is plain that the mode of proof also supposes the question of the divine origin of the Christian religion to be independent and to have precedence of the question of inspiration.

We shall close this article with a brief notice of the three most popular theories of inspiration, which are distinguished from each other more in respect of the extent to which they attribute inspiration, than in respect of any difference in the meaning assigned to the word.

That which is called verbal inspiration supposes each word in the Bible, as we now have it, with due allowance made for mistakes of transcribers, to have been irresistibly dictated by the Spirit of God, the writers being only vehicles of words and thoughts not their own. This notion of inspiration has undoubtedly still its advocates; but we are not aware that it is at present maintained by any divine of repute. According to another theory, somewhat modifying the former, the writers were allowed to exercise their own judgment in the choice of their words; but in the meaning of each sentence, from the first verse of Genesis down to the last of the Revelations, they have been secured by supernatural interference from the least particle of error. This theory, which is not without support from well-known theologians, represents perhaps more nearly than any other the popular creed. Lastly, there are many, and amongst them divines of great eminence and reputed orthodoxy, and not a few distinguished prelates of the English church, who limit the extent of inspiration as commonly received, and suppose that parts of Scripture may have been written with the liability to error incident to ordinary histories; those for instance which are purely historical, and contain no religious truth. As to the degree in which this limitation is to be admitted, and the number and length of passages to be excepted from the sanction of inspiration, there is of course room for diversity of opinions, which affords apparent ground for objection to the theory itself. The advocates of the two former theories contend that a latitude for choice is allowed which is capable of a dangerous abuse. The truth of the allegation cannot be disputed; but perhaps it is not possible by any device to exclude the danger which alarms them. The canon of Scripture has not been ascertained to us by an authoritative revelation, nor has the purity of the text been absolutely secured by providential interference. A liberty is thus left, which in these cases also may become dangerous to those who are willing to abuse it. Some however may think that the test of sincerity and right intention, and the means of probationary discipline which the allowance of such a measure of discretion affords, is apparently in harmony with what we have been taught of God's moral government of the world. On the other hand it is objected to the advocates of the more rigid theories, that the faith of the believer is exposed to still greater danger by the forced constructions and violent treatment of the text which their systems have often induced them to employ.

It might perhaps have been expected that we should notice a certain classification of the phenomena of inspiration of which many theologians are fond, certain distinctions in kind, under the titles of impulsive, suggestive, superintending, and many others. The truth is, we think them to be of very little value on any view of the subject. They seem to have been adopted by theologians who hold the theory of plenary but not verbal inspiration, from a wish to remove the necessity of supposing a greater quantity or degree of miraculous agency than the occasion required.

We have drawn none of our materials from the writings of a class of theologians who, regarding the Scriptures as in some sense, not very clearly defined, vehicles of religious truth, exclude all notion of revelation which is not equally applicable to discoveries made by human intelligence, and who give no credit to assertions of miraculous interposition, whether in conveying knowledge or attesting facts. Whatever consideration may be due to the writers, some of whom are men of ingenuity and research, their speculations could hardly have an appropriate place in treating of the subjects to which this article is confined. [RATIONALISM.]

REVELATIONS, BOOK OF. [APOCALYPSE.]

REVELS, MASTER OF THE, an officer in noblemen's and other great houses, appointed *pro tempore* to manage the Christmas diversions from All-hallow-eve to Candlemas-day: more ordinarily called the *Lord of Misrule*. In the royal household however the master of the revels was a permanent officer, and was called Master of the Tents and Revels or Masks and Revels, whose business it was to keep the tents and pavilions belonging to the king, which were often, if not always, carried with the king upon removes and progresses. This officer had also the keeping of the dresses and masks which were used in entertainments given at court, and he was to provide such new ones as were wanted.

The permanent office of master of the revels was first instituted in the reign of Henry VIII. Queen Elizabeth divided the mastership of the revels into several offices, which, as vacated by death, were to be re-united. In 1663 we find two masters of the toils, tents, hayles, (that is, halls or temporary buildings), and pavilions, who again occur in 1674.

See the 'Archæologia,' vol. xviii. p. 318, &c., and 'The Loseley Manuscripts,' edited by A. J. Kempe, Esq., 8vo., Lond., 1836. No mention of this office has been found subsequently to the reign of king Charles II.

REVERSION. By a reversion, in the widest sense, is meant a right of property the enjoyment of which is to commence at some future period, fixed or depending on contingencies, and is to continue either for ever or during a term either fixed or depending on a contingency: anything in fact which is to be entered on, or which may be entered on, at a future time, is a reversion in books which treat on the value of property. The legal sense of the word is more restricted.

Thus an assurance of 100*l.*, or a contract to pay 100*l.* at the death of a given individual, is 100*l.* in reversion to the executors of that individual. Our object in this article is to treat of this most common species of reversionary contract, life insurance or assurance.

The value of a reversion depends in a very easy manner upon the value of the corresponding annuity; that is, any given sum, say 100*l.*, to be received *when* a given event arrives, depends for its value upon that of 100*l.* a-year to be received *till* the event arrives. Suppose, for example, that money makes five per cent., and that an annuity, say upon a life, is worth fourteen years' purchase, upon the method of calculation explained in ANNUITY. That is, 100*l.* paid a year hence, and again two years hence, and so on as long as the life lasts, is now worth 1400*l.* Required the value of 100*l.* to be paid at the end of the year* in which the life drops. We must now reason as follows:—Suppose a perpetual annuity of 100*l.* a-year is to be enjoyed by A during his life, and by his legatees after him. By hypothesis A's portion is now worth 1400*l.*, and (money making five per cent.) the annuity for ever is worth 20 years' purchase, or 2000*l*; consequently the legatees' interest is *now* worth 2000—1400, or 600*l*. But at the end of the year of death the legatee will come into 100*l.* current payment, and a perpetual annuity worth 2000*l.*; for the remainder of a perpetual annuity is also a perpetual annuity: his interest will *then* be worth 2100*l.* Hence we have ascertained that 2100*l.* at the end of the year of death is now worth 600*l.*; and the rule of three then gives the value of any other sum: thus 100*l.* at the end of the year of death is now worth $\frac{600}{21}$*l.*, or 28*l.* 11*s.* 5$\frac{1}{7}$*d.* Hence the following easy

RULE.—To find the value of a given reversion, subtract the value of the same annuity from that of a perpetual annuity, and divide the difference by one more than the number of years' purchase in a perpetual annuity: or multiply the excess of the number of years' purchase in a perpetual annuity of 1*l.* over that in the life annuity by the reversionary sum, and divide as before.

Next, to find what premium should be paid for the reversion. A premium differs from an annuity in that a sum is paid down, and also at the end of every year: consequently it is worth one year's purchase more than an annuity. In the preceding question, the annuity was worth 14 years' purchase; consequently the premium now is worth 15 years' purchase. But the present value of all the premiums is to be also the present value of the reversion, or 28*l.* 11*s.* 5$\frac{1}{7}$*d.*, whence the premium should be the 15th part of this, or 1*l.* 18*s.* 1*d.* Hence to find the premium, divide the present value of the reversion by one more than the number of years' purchase in the life annuity. But when, as most commonly happens, the premium is wanted without the present value, the following is an easier

RULE.—Divide the reversionary sum separately by one more than the number of years' purchase in the perpetual annuity, and one more than the number of years' purchase in the life annuity: the difference of the quotients is the premium required. Thus if in the preceding example we divide 100*l.* by 20 + 1 and by 14 + 1, or by 21 and 15, we find 4*l.* 15*s.* 3*d.* and 6*l.* 13*s.* 4*d.*, which differ by 1*l.* 18*s.* 1*d.*, the same as before.

The life we have been tacitly considering, when we talked of an annuity being worth 14 years' purchase at five per cent., is one of about 36 years of age. The first impression must be, that the proposed premium is ridiculously small. Make it up to 2*l.*, and it will be 50 years before the premiums reach 100*l.* Some such consideration must have moved the law officers of the crown, in 1760, when they refused a charter to the Equitable Society, then charging a premium of about 4*l.* at the age of 36, on account of the lowness of their terms. But it is to be remembered that those who receive the premiums are to invest them immediately at five per cent., and are to invest the interest, thus making compound interest; persons aged 36 live, one with another, about 30 years, which is sufficient time for the premiums, with their interest, to realize 100*l.* for each person, one with another.

We now show the manner in which a simple result of calculation answers its end. To simplify the case, suppose an office starts with 5642 individual subscribers, each aged 30 years, the mortality among them being that of the Carlisle Table. [MORTALITY.] The bargain is for a temporary assurance, as it is called, of 20 years, and of 1000*l.*: that is to say, the executors of each one who dies within 20 years are to receive 1000*l.* at the end of the year of death. Money makes three per cent. once a year. According to the table, then, there are 57, 57, 56, &c. deaths in the successive years, and the following is the result, the proper premium being calculated at 11*l.* 12*s.* 3½*d.* each person, or more exactly 11,614*l.* 16*s.* for 1000 persons. It is supposed that there are no expenses of management. By P is meant that premiums are paid, and the number paid precedes the letter: by *y*, that a year's interest is received, and by *c*, that claims, in number as stated, are paid; small letters denote a transaction at the end of a year, and the large letter one at the beginning; the age of the parties paying premiums is in parentheses at the beginning. Fractions of pounds are neglected, 1*l.* being written for everything above 10*s.*

---

* Assurance companies usually pay in a few months after proof of death, which gives a trifling advantage to the assured, not worth considering in a very elementary statement of the question.

At the outset the office receives 65,530*l.* from the 5642 persons assured; this is immediately invested at 3 per cent., and yields 1966*l.* by the end of the year, making 67,496*l.* But at the end of the year the claims of the executors of 57 persons who have died during the year are to be satisfied, which requires a disbursement of 57,000*l.*, reducing the society's accumulation to 10,496*l.* The contributors who are left, 5585 in number, now pay their second premiums, 64,869*l.*, so that, these being immediately invested, the company has 75,365*l.* at interest during the second year. This yields 2261*l.*, so that by the end of the year 77,626*l.* is accumulated. Then comes the demand of 57,000*l.* on behalf of 57 contributors deceased during the year, which reduces the accumulation to 20,626*l.* This is more than it was at the same time last year, which is denoted by +. In this way the company goes on, accumulating to an amount which would lead a person unacquainted with the subject to conclude that the premium must be too large: in fact ten years give an accumulation of 91,809*l.* But now the state of affairs begins to change; the contributors have been diminishing, while the claims have been increasing, until the yearly incomings no longer equal the outgoings. The accumulations then come in to make good the difference in such manner that by the time the remaining contributors come to be 50 years of age, and the claims of 61 who died in their fiftieth year have been satisfied, there only remains 8*l.* of the 91,809*l.*; and this 8*l.* is merely the error arising from omitting shillings, &c., in the calculation. Something of the same kind must take place in every office which dies a natural and a solvent death: the only difference being that, when new business ceases, instead of a number of contributors all of the same age, and under similar contracts, both ages and contracts vary considerably.

There are certain tables which are variously named (sometimes after Mr. Barrett, the inventor; sometimes after Mr. Griffith Davies, the improver; sometimes after D and N, letters of reference used in them), but which we call commutation tables. They are described in the 'Treatise on Annuities,' in the 'Library of Useful Knowledge,' and a copious collection is given: also in an article in the 'Companion to the Almanac' for 1840. They very much exceed in utility those which preceded them; and we shall here give part of one of them, namely, that for the Carlisle Table, at 3 per cent., which contains the materials for judging of the demands made by an insurance company in cases involving one life only. Opposite to each age of life are three rows of figures in columns marked D, N, and M; and by M (*x*) we mean the number in column M opposite to the age *x*.

To find the value of an annuity of 1*l.* on a life of any age, divide the N of that age by its D. Thus at the age of 35 the value of an annuity of 1*l.* is N(35) ÷ D(35), or 35126·57 ÷ 1905·57, or 18·433*l.*, or 18*l.* 8*s.* 8*d.* Thus, the following formulæ will be readily understood:—

Value of an annuity which is to commence immediately; that is, which is to make the first payment in a year (age x) . .	$\frac{N(x)}{D(x)}$
Value of an annuity which is to commence in n years; that is, to make the first payment in $n+1$ years, if the party be then alive (present age x) . . .	$\frac{N(x+n)}{D(x)}$
Premium for such an annuity, payable now and n times in all	$\frac{N(x+n)}{N(x-1)-N(x+n-1)}$
The same premium, payable $n+1$ times .	$\frac{N(x+n)}{N(x-1)-N(x+n)}$
Value of a life annuity for n years; or payable n times at most . . .	$\frac{N(x)-N(x+n)}{D(x)}$
Present value of an assurance of 1*l.* at death	$\frac{M(x)}{D(x)}$
Premium for the same	$\frac{M(x)}{N(x-1)}$
Present value of an assurance of 1*l.* at death if after n years	$\frac{M(x+n)}{D(x)}$
Premium for the same, payable $(n+1)$ times	$\frac{M(x+n)}{N(x-1)-N(x+n)}$
Present value of an assurance of 1*l.* at death if within n years	$\frac{M(x)-M(x+n)}{D(x)}$
Premium for the same, payable n times .	$\frac{M(x)-M(x+n)}{N(x-1)-N(x+n-1)}$

As an instance, let us take the case of the last formula, which was proposed at the beginning of this article: the age is 30, and the term of insurance 20 years; we have then to divide the excess of M (30) over M (50) by the excess of N (29) over N (49):—

M (30)	932·6867	N (29)	48783·19
M (50)	555·9583	N (49)	15347·98
	376·7284	div. by 32435·21 gives ·0116148:	

this is for 1*l.*, giving 11·6148*l.*, or 11*l.* 12*s.* 3½*d.* for 1000*l.*, and 11,614·8*l.* to be the total premium for 1000 persons.

Question.—If the office insure a large number of persons (for the whole life or a term) at the premium p (the age being x), what will be their accumulation in n years, upon the suppositions the working of which has been shown in the example already given; it being supposed that £A is insured to every one who dies? The answer is in the following formula: for every person who, according to the tables, is alive at the end of the term of n years, there is remaining in the office, after all claims have been paid up to the end of the n years, and before the $(n+1)$th premium is paid, the sum

$$\frac{p\,\{N(x-1)-N(x+n-1)\}-A\,\{M(x)-M(x+n)\}}{D(x+n)}$$

As an example we shall verify the accumulations of 10 years in the instance referred to; in which $p = 11·6148l.$, $A = 1000l.$, $x = 30$, $n = 10$.

```
         N(29) 47783·19          M(30) 932·6867
         N(39) 28225·55          M(40) 733·6727
               --------                --------
               19557·64                199·0140
             × 11·6148                 × 1000
               --------                --------
               227158·1                199014·0
               199014·0
               --------
                28144·1
      D(40)       1555·78)28144·1(18·09002
                                   × 5075
                                   --------
                                   91806·84
```

The answer is, that the reserve of premiums for each person of the 5075 then remaining is 18·09002*l.*, which for the whole is 91806·84*l.* The rough answer in the scheme worked out at length is 91,809*l.*

Now, this 18·09*l.*, or 18*l.* 1*s.* 10*d.*, is what is called the value of each man's policy at the expiration of the ten years; or the *very utmost* the office could afford to give him to surrender all claim, and to keep his future premiums to himself. But what is the nature of his claim on the office? Evidently this, that he has a right to make them give him a guarantee for the next ten years on payment of a premium of 11*l.* 12*s.* 3½*d.*, which could not be done at so low a rate for a new comer. Compute the premium for a person entering at 40, and insuring 1000*l.* for 10 years; or divide 1000 times M(40)−M(50) by N(39)−N(49), and the answer will be found to be 13·800*l.*, or 13*l.* 16*s.* If then any person aged 40, having been in the office ten years, were to put another person of the same age in his place at his own premium, he would obviously make that person a present of the difference between 11·6148*l.* and 13·800*l.*, at once (since a premium is to be paid immediately), and for nine succeeding years, if the latter should live so long. And 13·800−11·6148 is 2·1852, while an annuity of 2·1852*l.* for nine years, at the age of 40, is worth N(40)−N(49) divided by D(40) and multiplied by 2·1852, or 15·903*l.* Add to this 2·185*l.* for the immediate difference, and we get 18·088*l.*, differing only a halfpenny from 18·090*l.*, the sum which the office has in reserve. If then the person who is to take the place of the insured at 40 years of age, were to pay him an equivalent, he must, besides taking on himself the future premiums, pay the retiring member 18·090*l.*, which is therefore the value of the latter's policy. The last formula will always give the *accumulation* value of a policy, whether for the whole life or for a fixed term.

The preceding contains the most material calculations which are necessary in the management of an office, or rather, in forming an opinion on the management of an office. It is to be remembered that all which has hitherto been said supposes the rates of mortality and interest to be absolutely known and invariable, the parties to enter on their birthdays, and all claims to be adjusted at the terminations of whole years from the time of entry. We now proceed to the application.

An assurance company is a savings' bank, with a mutual understanding, presently to be noticed, between the contributors. To make out this proposition, let us suppose that A borrows money, and insures his life for the amount as a security to his creditor. For this he has to pay a premium. If life were certain, the office of the company would be to receive and invest these premiums, which would be calculated in such a manner as with their interest to amount to a sum sufficient to discharge the loan in a settled time. At the end of this time the creditor (who has been all this while receiving interest for his money from A) calls upon A to make his claim upon the office, and repay the loan with the money received. If such an office existed, life being certain, the rationale of the proceeding would be that the creditor, though tolerably confident of A's power and willingness to make any yearly payment, whether of interest or instalment, will not trust him steadily to lay by and improve yearly instalments, but requires that he should make his instalments payable to third parties, who are engaged not to return them on demand until they amount to a sum sufficient for the discharge of the debt. Such an office certainly could not exist, on account of the uncertainty of individual life. So soon however as it is known that the duration of masses of individuals can be calculated with tolerable accuracy, there is a remedy for the individual uncertainties. Let a large number of debtors, similarly situated with A, agree to be guarantees for one another; that is, let each of them pay during his life not only his own instalments, but such additional sums as will provide the means of meeting the deficits of those who die, and the savings' bank thus constructed will become an assurance office. Of course it matters nothing whether these debtors pay their instalments to a person agreed on among themselves, or go to a company which undertakes the management of such concerns. And again, it makes no difference whether the instalments be for liquidation of debt, or to accumulate a provision for widows and children. We have taken the case of debtors, because in such a case an office looks more like a mere indemnity-office than when its contributors enter for the benefit of their families; still however, in the former case, it is evident that the premiums are partly instalments of debt, partly sums intended to make good the deficiency of the life-instalments of those who die.

Let us now suppose a company to be formed for the simple purpose of assuring lives. Their business is to invest the premiums of those who assure with them; their receipts will consist entirely of current premiums and interest on the investments of the old ones; and their outgoings will contain expenses of management, payment of claims, purchase of their own policies, and (possibly) losses by bad investment.

There is one question which is generally settled at the very outset, namely, whether the company is to be what is called mutual, proprietary, or mixed.

A mutual company is one in which the members stand bound to each other, and constitute the company themselves. In such a company no capital is, generally speaking, raised at the outset, except a small sum for necessary expenses at starting. This however is not necessarily the feature of a mutual company; for if its members choose to constitute themselves an investment company as well as an assurance company, they may, without losing their *mutual* character, require every assurer to be also a shareholder. In a mutual company the profits of course are divided among the assured.

A proprietary company is one in which a body of proprietors raise a capital and pledge it for the payment of claims, in case the premiums are not sufficient: for this security they receive, in addition to the interest of their own capital, the profits of the assurance business. It has long been proved that, with proper tables of premiums, and a fair amount of business at starting, this capital is an unnecessary security; and the only reason which could now make such an office desirable, would be the lowness of its premiums. Of course it matters nothing to the assured how claims are paid, as long as they *are* paid; the capital may be diminished, but the assurer fears nothing except its exhaustion before his turn comes. This must be the sole consideration with a person who is tempted by low premiums to a purely proprietary office: the nominal capital signifies nothing; it is upon the amount of assurance to which it (with the premiums) is pledged that the solvency of the office depends. Generally speaking however we believe it will be found that the purely proprietary offices have not allowed themselves to run much risk.

A mixed office is one in which there is a proprietary company, which does not take all the profits, but a share; the rest being divided among the assured. The only good effect of the capital upon the condition of the assured in such a company is this; that the directors, having fixed capital as well as premiums, may justifiably seek for investments which a mutual company must avoid. Having the capital to make good purely commercial losses, they may perhaps attempt to get a higher rate of interest, and of course take more risk of loss; the assured, who are sharers in the whole of the profits, since the profits of premiums and profits of original capital are not distinguished, come in for their share of the extra profits of the capital. But no such attempt at gaining higher interest by secondary securities should be made until a sum sufficient (with future premiums) to meet all claims is invested in the very safest securities which the state of society offers.

There is much confusion in the ideas of many persons about interest, arising from not distinguishing between interest and other returns. The following remarks may serve to explain our meaning:—

Interest is the return which is made for the use of money, when the owner entirely relinquishes its management, and believes he has undoubted security for its return. "Interest," says Mr. M'Culloch, "is nothing more than the net profit on capital." The same author goes on to say, "the rate of interest on each particular loan must of course vary according to the supposed solvency of the borrowers, or the degree of risk supposed to be incurred by the lender." But here the acute writer from whom we quote, after setting out with the accurate definition of the political economist, proceeds to use the word in the common sense, in which it is no longer the net profit of capital. For this variation in the rate of interest (so called), this addition for possible insolvency, is or is meant to be only as much as will make every debtor who does pay contribute towards the bad debts of those who do not. Nothing then is netted by the increase for suspicion of insolvency, in the long run, and one debt with another; so that, abiding by Mr. M'Culloch's definition of interest as the correct one, we should propose to call the additional sum debt-insurance. To this we must add, that when a person employs his own money, as in trade or manufactures, he also gains that additional return which a borrower counts upon reserving to himself after paying the interest (and debt-insurance, if any) to his creditor. This is neither interest nor debt-insurance, but is of the nature of salary, by which name it might be called. Perhaps it would be best to retain the term interest in its general loose signification, and to subdivide it, for accuracy, into pure interest or net profit, debt-insurance, and salary.

In the construction of a table of premiums, three points must be left to the judgment of the constructor, the rate of interest, the table of mortality, and the addition to be made for expenses of management and probable fluctuation, or discrepancy between the predictions of the table and the events which actually arrive. The third point would not arise if, as was once the case, the table of mortality made life much worse than the actually prevailing state of things shows it to be. Security against adverse fluctuation is thus taken in the choice of the tables; and this was done by the older offices, which chose the Northampton Table,—by the Equitable, for instance. (Compare the mean duration of life in the Northampton Table with that of the Equitable experience, in MORTALITY.) But we hold decidedly by the method of choosing a true table, and augmenting the premiums given by it as a safeguard against fluctuation; and for this reason, that wrong tables are usually unequally wrong, making different errors at different ages, and thus augmenting different real premiums by different percentages.

According to the Carlisle Table (which we prefer for the purpose), of 5642 persons alive at the age of 36, 3018 are alive at 65, whence the chance of living till the second age is 3018 ÷ 5642 or ·5525. Now, by applying calculation to this question, we find that an office which would have practical certainty (thousands to one for it) that, so far as this instance is concerned, the office should not be injured by adverse departure of events from tables, must make provision for twenty-five deaths, at least, in the period above-mentioned, more than the tables predict. And this even on the supposition that the table itself can be certainly reckoned upon as representing the law of mortality of the whole insurable population. It would be a very long process indeed to apply calculation in detail, so as to form a well-supported idea of the proper amount of precaution against fluctuation; and the question is mixed up with another, to which we proceed.

The rate of interest to be assumed is an element which requires the greatest caution. It must be a rate which can actually be made, and therefore prudence requires that it should be something below that which may reasonably be looked for. To show how powerful an agent it is, we shall repeat the example already given, of the 5642 insurers for twenty years, on the supposition that the office which charges as for 3 per cent. finds itself able to make 3½ per cent.

It thus appears that the office leaves off with an accumulation of 15,441*l*. nearly; and if it be lucky during the first years, it may be said to be safe (as we find) against any fluctuation for which there is an even chance, by the increase of interest alone.

Take what amount of precaution we may, an office must, at first starting, depend upon something either of capital or guarantee. Even a mutual office must raise something at the outset. Tables must be constructed with very large additions to the calculated premiums, which are to meet the very earliest contingencies alone; indeed it is difficult to say what addition would be too large. But this point it is unnecesary to insist on, since we can hardly suppose it possible that any set of men would found an office with no resource except premiums from the very commencement. Supposing proper precautions to be taken, we imagine that an addition of 25 per cent. to premiums calculated from the Carlisle Tables at 3 per cent. per annum, is sufficient to place a mutual office upon a sound footing, and to give a very great prospect of a return in the shape of what is called profit. It never has been found that an office charging at this rate has been without surplus of some kind.

This surplus has been called by the inaccurate name of profit, whereas it is really that part of the security against fluctuation of interest and mortality which has been found to be unnecessary. In mutual offices it is to be returned to the assured in an equitable manner; in purely proprietary offices it is really profit to the proprietors, whose capital has yielded them the ordinary interest, since by hypothesis none of it has been necessary to meet claims, and they therefore share among themselves the residue of the premiums. It is impossible to avoid this surplus in a well-constituted office, for the mathematical line which separates surplus from deficiency cannot be expected to be attained, so that those who would not have the latter must take care to have the former.

The questions connected with life assurance, &c., have become so many and so important that it is impossible to enter on the subject, with reference to the points actually discussed in our own day. The scientific reader will find in the pages of the 'Assurance Magazine,' materials for thought on most of these subjects. For others, we know of no work which gives so much information, and which so well enables the reader to refer all statements to their real sources, as an anonymous work, 'The Assurance Guide and Handbook,' London, 8vo, 1857 (published by W. S. D. Pateman, pp. 440). This work professes to be intended for insurance agents, and, so far as we can find, has no leaning to any particular offices or systems.

REVERSION OF SERIES. In the nomenclature of mathematics, which is far from being consistent with itself, the words *reversion* and *inversion* are sometimes confounded. Thus the term by which we describe the square root, as connected with the square, is, that each is an INVERSE process to the other; but if y be a given series of the powers of x, the determination of x in a series of functions of y is not called inversion, but reversion. Various points connected with reversion (to keep the common term) will be met with in TAYLOR'S THEOREM and SERIES; the present article is meant purely for reference upon the most usual case of the problem, which is not sufficiently developed in elementary works; that is, enough of the result for reference is not put down.

The problem is as follows:—Given $y = ax + bx^2 + cx^3 + ex^4 + fx^5 + \ldots$; required x in a series of the form $\text{A}y - \text{B}y^2 + \text{C}y^3 - \text{E}y^4 + \ldots$. It will be proper first to put down the coefficients in connection with the exponents to which they belong, as follows:—

1	2	3	4	5	6	7	8	9	10	11
a	b	c	e	f	g	h	k	l	m	n
A	B	C	E	F	G	H	K	L	M	N

It will be convenient, instead of writing the resulting series $\text{A}y - \text{B}y^2 + \ldots\ldots$, to let it be $\text{A}a^{-1}y - \text{B}a^{-3}y^2 + \text{C}a^{-5}y^3 - \text{E}a^{-7}y^4 + \text{F}a^{-9}y^5 - \text{G}a^{-11}y^6 + \text{H}a^{-13}y^7 - \text{K}a^{-15}y^8 + \text{L}a^{-17}y^9 - \text{M}a^{-19}y^{10} + \text{N}a^{-21}y^{11} - \ldots\ldots$ We then have

$\text{A} = 1$

$\text{B} = b$

$\text{C} = 2b^2 - ac$

$\text{E} = 5b^3 - 5abc + a^2e$

$\text{F} = 14b^4 - 21ab^2c + 3a^2(2be + c^2) - a^3f$

$\text{G} = 42b^5 - 84ab^3c + 28a^2(b^2e + bc^2) - 7a^3(bf + ce) + a^4g$

$\text{H} = 132b^6 - 330ab^4c + 60a^2(2b^3e + 3b^2c^2) - 12a^3(3b^2f + 6bce + c^3) + 4a^4(2bg + 2cf + e^2) - a^5h$

$\text{K} = 429b^7 - 1287ab^5c + 495a^2(b^4e + 2b^3c^2) - 165a^3(b^3f + 3b^2ce + bc^3) + 45a^4(b^2g + 2bcf + be^2 + c^2e) - 9a^5(bh + cg + ef) + a^6k$

$\text{L} = 1430b^8 - 5005ab^6c + 1001a^2(2b^5e + 5b^4c^2) - 715a^3(b^4f + 4b^3ce + 2b^2c^3) + 55a^4(4b^3g + 12b^2cf + 6b^2e^2 + 12bc^2e + c^4) - 55a^5(b^2h + 2bcg + 2bef + c^2f + ce^2) + 5a^6(2bk + 2ch + 2eg + f^2) - a^7l$

$\text{M} = 4862b^9 - 19448ab^7c + 8008a^2(b^6e + 3b^5c^2) - 1001a^3(3b^5f + 15b^4ce + 10b^3c^3) + 1001a^4(b^4g + 4b^3cf + 2b^3e^2 + 6b^2c^2e + bc^4) - 286a^5(b^3h + 3b^2cg + 3b^2ef + 3bc^2f + 3bce^2 + c^3e) + 22a^6(3b^2k + 6bch + 6beg + 3c^2g + 3bf^2 + 6cef + e^3) - 11a^7(bl + ck + eh + fg) + a^8m$

$\text{N} = 16796b^{10} - 75582ab^8c + 15912a^2(2b^7e + 7b^6c^2) - 12376a^3(b^6f + 6b^5ce + 5b^4c^3) + 2184a^4(2b^5g + 10b^4cf + 5b^4e^2 + 20b^3c^2e + 5b^2c^4) - 273a^5(5b^4h + 20b^3cg + 20b^3ef + 30b^2c^2f + 30b^2ce^2 + 20bc^3e + c^5) + 182a^6(2b^3k + 6b^2ch + 6b^2eg + 6bc^2g + 3b^2f^2 + 12bcef + 2c^3f + 2be^3 + 3c^2e^2) - 78a^7(b^2l + 2bck + 2beh + c^2h + 2bfg + 2ceg + cf^2 + e^2f) + 6a^8(2bm + 2cl + 2ek + 2fh + g^2) - a^9n.$

We have given these coefficients to an extent which many will think useless, and in fact it will not often be necessary to employ all that are here given. But we have two objects in view: first, to enable those who want these coefficients to refer to them; secondly, to point out the great advantage of some methods which are never given in elementary works, and are not so much known and practised as methods of such utility and power should be.

The usual way of obtaining these results is to take the series $x = \text{A}a^{-1}y - \text{B}a^{-3}y^2 + \ldots\ldots$, and in it to substitute the value of y, namely, $ax + bx^2 + \ldots$. This would give

$$x = \frac{\text{A}}{a}(ax + bx^2 + \ldots) - \frac{\text{B}}{a^3}(ax + bx^2 \ldots)^2 + \ldots,$$

the two sides of which equation must be identical; giving

$$\text{A} = 1,\ \text{A}\frac{b}{a} - \text{B}\frac{1}{a} = 0, \text{ or B} = b;$$

$$\frac{\text{A}}{a}c - \frac{2b}{a^2}b + \frac{\text{C}}{a^2} = 0, \text{ or C} = 2b^2 - ac,$$

and so on; but this process would become intolerably tedious and liable to error after a few steps: that which we have followed in forming the preceding coefficients [TAYLOR'S THEOREM] would have enabled us with comparatively little difficulty and small risk of error to double their number. It also gives the law of the coefficients, which is as follows:—

1. What sort of terms enter into M, the coefficient of y^{10}? Write down every way in which 2 . 10 − 2, or 18, can be made up of 10 − 1, or 9, numbers, and, taking the letters belonging to these numbers from the table, we have the literal parts of the different terms of the coefficients. Thus

18 is made up of the nine numbers, 1, 1, 1, 1, 2, 2, 2, 2, 6, the letters of which are $a, a, a, a, b, b, b, b, g$: accordingly, a^4b^4g is the literal part of one of the terms of M. And similarly for every other combination of nine numbers which make 18.

2. What is the coefficient of any given term? Say that y^n is the power to which the term belongs, and that $a^\alpha b^\beta c^\gamma \ldots$ is the literal part of it. The coefficient required is as follows:

$$\frac{(n+1)(n+2)\ldots\ldots(2n-\alpha-2)}{(1.2.3\ldots.\beta)(1.2.3\ldots.\gamma)(1.2.3\ldots.\delta)\ldots.}$$

Thus, to verify the numerical coefficient of $a^6c^2e^2$ in N, the coefficient of y^{11}, we must calculate ($n = 11$, $\alpha = 6$, $2n - \alpha - 2 = 14$),

$$\frac{12\,.\,13\,.\,14}{(1\,.\,2)\,(1\,.\,2)}, \text{ which is } 6\,.\,13\,.\,7, \text{ or } 546,$$

and 182 × 3, the coefficient in the table, is also 546.

2. The sign of any term is positive or negative according as the power of a which it contains is even or odd.

We may thus verify any one term, and the coefficients may be sufficiently verified, as to typographical correctness, by remembering, that if $a = b = c = \&c. = 1$, we should have $\text{A} = \text{B} = \text{C} = \&c. = 1$; for $y = x + x^2 + x^3 + \ldots$ gives $x = y - y^2 + y^3 - \ldots.$ The result of the use of the preceding table, distinguishing the positive from the negative parts, is

$$x = y - y^2 + (2-1)y^3 - (6-5)y^4 + (23-22)y^5 - (99-98)y^6 + (452-451)y^7 - (2140-2139)y^8 + (10397-10396)y^9 - (51525-51524)y^{10} + (259430-259429)y^{11}.$$

The preceding is a particular case of the following general problem, which frequently occurs, and is very complicated in its details. Given $y_m = ax^m + bx^{m+1} + cx^{m+2} + ex^{m+3} + fx^{m+4} + \ldots$; required a series for x in powers of y. Let it be assumed that

$$x = \text{A}\frac{y}{a^n} - \text{B}\frac{y^2}{a^{2n+1}} + \text{C}\frac{y^3}{a^{3n+2}} - \text{E}\frac{y^4}{a^{4n+3}} + \text{F}\frac{y^5}{a^{5n+4}} - \ldots\ldots$$

n being $1 . m$. Then $\text{A} = 1$, $\text{B} = nb$:

$$\text{C} = n\frac{3n+1}{2}b^2 - n\,ac$$

$$\text{E} = n\frac{4n+1}{2}\,\frac{4n+2}{3}b^3 - n\frac{4n+1}{2}2abc + n\,a^2e$$

$$\text{F} = n\frac{5n+1}{2}\,\frac{5n+2}{3}\,\frac{5n+3}{4}b^4 - n\frac{5n+1}{2}\,\frac{5n+2}{3}3ab^2c$$

$$+ n\frac{5n+1}{2}a^2(2be + c^2) - n\,a^3f$$

Methods of obtaining all these series are given in TAYLOR'S THEOREM.

REVERSION. "Reversion of land is a certain estate remaining in the lessor or donor, after the particular estate and possession conveyed to another by lease for life, for years, or gift in tail. And it is called a reversion in respect of the possession separated from it; so that he that hath the one, hath not the other at the same time, for being in one body together, there cannot be said a reversion, because by the uniting, the one of them is drowned in the other. And so the reversion of land is the land itself when it falleth." ('Termes de la Ley.') Thus if a man seised in fee simple conveys lands to A for life, or in tail, he retains the reversion in fee simple. The distinction between a remainder and a reversion has been explained in REMAINDER. In all cases where the owner of land or the person who has an estate in land, grants part only of his estate, he has a reversion; and as the grantee holds of him, there is tenure between them, and the grantor has a seignory by virtue of having a reversion. When a man grants all his estate to another, or grants a particular estate to A, and various remainders over, remainder to F in fee, he has no reversion left, and therefore he has no seignory since the passing of the statute of Quia Emptores. The remainder-men also who precede the remainder-man in fee, do not hold of such remainder-man, but of the lord of the fee of whom the original owner held. The word reversion is often used inaccurately, and it is sometimes necessary to recur to its strict legal signification.

Before the passing of the statute De Donis, if a man seised in fee simple granted his lands to a man and the heirs of his body, he had no reversion, for the grantee was considered to have a conditional fee. But since this statute, an estate to a man and the heirs of his body has always been considered to be a particular estate.

If a man grants a lease of lands in possession, at common law, he has no reversion until the lessee enters by virtue of his lease, for the lessee has no estate until he enters; but if the term of years is created under the Statute of Uses, as by bargain and sale, the lessee has a vested estate by virtue of the statute, without entering on the land, and consequently the lessor has a reversion. It is said that a reversion cannot be created by deed or other assurance, but arises from construction of law. This means that a reversion is not created by the act of the party who conveys part of his estate, but is a legal consequence of his acts. If a man seised in fee simple limits his estate to another for life or in tail, remainder to himself in fee or to his own right heirs, he has not a remainder, but a reversion. Yet by 3 and 4 Wm. IV. c. 106, the effect of such a limitation is to vest such a remainder in fee in the settlor by *purchase*, and he is not to be considered to be entitled to it as his former estate or part thereof.

A reversion is a vested estate, which may be granted or conveyed, and charged like an estate in possession; and in some cases the reversioner in fee may bring an action, as well as the tenant in possession, for an injury to his inheritance.

Fealty is an inseparable incident to a reversion. There may or may not be a rent reserved, but fealty is always due from the owner of the particular estate to the reversioner, and it cannot be separated from the reversion, though the rent, if there be one reserved, may be separated from it. [Rent.] Reversions which are expectant on estates for years are subject to dower and courtesy; but this is not the case with reversions expectant on a freehold estate.

When a reversion expectant on an estate tail comes into possession, it is liable to the leases made by those who were at any time entitled to the reversion, and to the covenants contained in such leases. All particular estates, except an estate tail, are subject to merge in the reversion, when the particular estate and the reversion are united in the same person. Formerly when an estate tail was converted into a base fee, and the remainder or reversion in fee in the same lands became united in the same person, the base fee was subject to merger in the reversion; but by the 3 and 4 Wm. IV. c. 74, when such union takes place, "the base fee shall not merge, but shall be *ipso facto* enlarged into as large an estate as the tenant in tail, with the consent of the protector, if any, might have created by any disposition under this Act, if such remainder or reversion had been vested in any other person." Before this statute, when a base fee thus merged in the reversion, the reversion became an estate in possession, and liable to all the leases and charges of those who had at any time been entitled to it.

REVETMENT, in permanent fortification, is a wall of brick or stone retaining the mass of earth which constitutes the rampart, generally on the exterior side only, or retaining the earth which forms the opposite side of the ditch. The exterior faces of these walls are considered as the scarp and counterscarp of the ditch.

In and before the time of Vauban the scarp revetments were raised from the bottom of the ditch to the top of the parapet; but the part which was visible above the glacis being destroyed by the enemy's artillery, and the parapet in consequence partly ruined soon after the commencement of the siege, that engineer in most of his works raised his revetments no higher than the level of the crest of the glacis, or about 7 feet above the natural ground; the exterior of the parapet was then left at such an inclination to the horizon (45° in general) that the earth would support itself. The ditch of a fortress being about 18 feet deep, the height of the scarp revetment was consequently 25 feet, and this was considered sufficient to afford security against the danger of having the rampart escaladed. At present it is recommended that the main ditch should be 24 feet deep, and in this case the scarp revetment is above 30 feet high. In constructing the fortifications of Neuf Brisac, Vauban made the revetments of the scarps both of the enceinte and of the reduit of the ravelin, as high as the top of the parapet; but these works being covered by the counterguard or the ravelin, their revetments would be unseen by the enemy at a distance, and therefore not liable to the objection above mentioned.

The form usually given in profile to revetments of masonry may be seen at M and N, *Fig.* 2, Bastion; the first is the revetment of the counterscarp, and the other that of the scarp. The rectangular parts are sections through the counterforts or buttresses which are built up with the walls in order to strengthen them, at intervals of about 15 feet from each other. Scarp revetments, whose tops are as high or higher than the crest of the glacis, are called full revetments; while such as are no higher than the level of the natural ground are called demi-revetments.

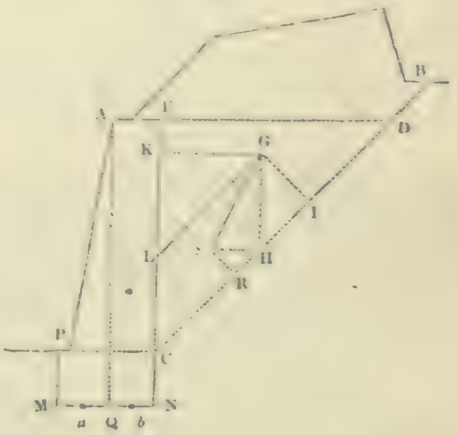
In order that the revetment might most effectually resist the pressure of the earth which it is to support, Vauban gave to the exterior face of the wall a slope, whose horizontal breadth was equal to one fifth of the height; this was subsequently reduced to one sixth, and now it is thought to be most advantageous to make the face vertical. By giving the slope to the rear face of the wall, that is, by making the revetment countersloping, all the advantages of a slope are gained, while the disadvantage of rapid vegetation on the face is avoided.

In laying the foundations of revetments in defective soils, the same methods are used as in the construction of civil edifices; and in all cases the courses of stones or bricks are laid obliquely to the horizon, inclining down towards the part under the earth which is to be supported, in order that the pressure of the latter may be more directly resisted. But as the bed joints of brickwork when so disposed allow the rain to penetrate, and the seeds of grass to lodge in them, it is thought that the wall is more speedily degraded when so built than when the courses are laid horizontally; therefore in order to unite the advantages of direct resistance and durability, it is customary to place the courses obliquely, but to lay one row of bricks in each course at the face of the wall in a horizontal position.

The exterior and interior faces of the revetment, or retaining wall of a dock, have in a vertical section the form of concentric arcs of circles, with their convexities towards the land; and this form is given them that the stones may be able to resist the hydrostatical pressure of any water which, when the dock is full, may get behind the wall, and which may be prevented from escaping when the dock is made dry.

Some of the ramparts of Coehorn and all of those which Carnot proposed for his fortresses, are formed of earth unsupported by revetments; and even the opposite side of the ditch, instead of being faced with a steep wall, is by the latter engineer cut with a gentle slope from the level of the natural ground to the bottom of the ditch. But the fortifications of Coehorn are provided with wet ditches, which prevent the besiegers from getting to the foot of the rampart by surprise: and in those of Carnot a high detached wall covered by a counterguard of earth puts it out of the power of the enemy, while that wall stands, to get across the ditch. Without such obstacles the unreveted rampart would afford great facilities to the enemy in an effort to carry the fortress by assault. Its exterior slope must form at most an angle of 45° with the horizon, that the earth may support itself, and consequently it may be easily ascended; and any palisades or other impediments which the defenders might place on it would soon be displaced or destroyed by the batteries of the enemy. Besides these evils, the exterior slope, from its breadth, occupies a great portion of ground; it consequently obliges the engineer to contract the space enclosed within the works, and thus to sacrifice in some measure the convenience both of the inhabitants and the garrison.

In order to investigate the conditions of stability in revetment walls, let E B C be a vertical section through the mass of earth retained by the wall; B C being the slope which earth is supposed to assume when unsupported, and let A E M N be a section of the wall, E C being the level of the bottom of the ditch, and M N being the bottom of the foundation. Imagine G to be the centre of gravity of the section E C B; draw G L parallel to B C and G K parallel to the horizon: then, by the resolution of forces, K L and G K will have to one another the same proportion that the weight of the unsupported prism of earth (of any thickness) bears to its horizontal pressure. Let W be that weight; then $\frac{\text{K G}}{\text{K L}}$ will express that pressure, and $\frac{\text{K G}}{\text{K L}}.\text{W}.\text{K N}$ will be the momentum or power by which the earth tends to overturn the wall about M.



Imagine the vertical line A Q to be drawn: then the form and dimensions of the part A M Q of the wall are known; and let it be required to find the breadth Q N of the rectangular part A N, so that the resistance of the whole shall be equal to the momentum of the supported earth. Suppose the centre of gravity of A M Q to be found, and let it be vertically over a. The centre of gravity of the rectangular part is vertically over b, the middle of Q N; and let Qb be represented by x. Then if g be the specific gravity of the wall, we have by mechanics, $\text{AMQ}\,.\,\text{M}a\,.\,g+\text{AQ}\,.\,\text{M}b\,.\,g\,.\,x$ for the resistance of the wall; consequently equating this expression with the above momentum of the earth, the value of x, and therefore of Q N, can be found. But great uncertainty exists respecting the position of the line of rupture B C, from our ignorance of the allowance to be made for the effect of friction on the tendency of the earth to slide downwards. Experiments have led to the opinion that this effect is equal to half the pressure of the earth perpendicularly upon the inclined plane which it would assume if unsupported; and that value is frequently adopted. Coulomb showed that the angle which the line of rupture makes with the vertical is half the angle which the line of natural slope makes with the vertical.

In order to find the magnitude which the triangle E D C should have when the supported earth exerts the greatest pressure against the wall, the following process may be used; the earth above A D being at present, for simplicity, supposed to be removed. Imagine G to be the centre of gravity of that triangle, and the vertical line G H to be drawn; then G H may represent the weight of the unsupported earth, and let it be resolved into the pressures represented by G I and I H, the former perpendicular to the slope, and the latter coincident with it. Imagine H S to be drawn to represent the reaction of the wall A M N, and let it be resolved into the forces represented by S R and R H, perpendicular to and coincident with the slope, respectively. Then, I H representing the force with which the prism of earth would tend, if without friction, to slide down D C, R H represents the reaction by which the wall resists that force; while G I and S R represent the pressure and reaction perpendicular to D C. Consequently, the friction being supposed to be equal to half the pressure, we have $\frac{1}{2}(\text{G I}+\text{S R})$ for the effect of friction; and in the case of equilibrium, $\text{I H}=\text{R H}+\frac{1}{2}(\text{G I}+\text{S R})$.

Let $\text{E C}=h$, $\text{E D}=z$, $\text{H S}=p$, and let g be the specific gravity of the earth; then $\frac{hgz}{2}$ expresses the weight of the prism whose section is E D C, and whose thickness is unity, and which was represented by G H; and the triangles G I H, H S R being similar to E C D, we get by proportions $\text{I H}=\frac{h^2gz}{2\,\text{C D}}$, $\text{H R}=\frac{pz}{\text{C D}}$, $\text{G I}=\frac{hgz^2}{2\,\text{C D}}$, and $\text{S R}=\frac{ph}{\text{C D}}$. These values being substituted in the above equation, the value of the pressure H S or p will be found to be $\frac{h}{2}g \cdot \frac{2hz-z^2}{2z+h}$. Now this quantity is to be a maximum; therefore making its differential relatively to z equal to zero, the value of z will be found to be $\cdot 618h$; whence $p=\cdot 1908\,g\,.\,h^2$. If this equation be differentiated relatively to h, the result will express the horizontal pressure against an elementary portion of the wall at a variable height (which represent by h) above C: therefore multiplying by h and integrating, we get $\cdot 1272\,g\,h^3$ for the whole force exerted by the earth to overturn about M a wall whose height E C is represented by h, when that force is a maximum. When there is a parapet above A D, its weight, expressed by the product of the area of the section multiplied by g, must be added to the above expression for the weight of the prism E D C in the preceding investigation, in order to obtain the value of the expression which is represented by G H.

Instead of making a revetment in the form of a simple wall, it is customary to build buttresses or counterforts at intervals from each other on the side next to the supported earth; consequently the thickness of the wall itself may be rather less than that which would result from the above equation. In order to determine it, if we assume, for example, that the distance from the centre of one counterfort to that of the next is fifteen feet, the area of a horizontal section fifteen feet long and taken at the mean height of the wall, if the face has a slope, together with the area of the like section through the two half counterforts, may be equal to the area of a section of the simple wall (of the same length) as determined by the above investigation; then deducting one-fifth of that quantity for the two half counterforts, the remainder divided by 15 will give the required breadth of a horizontal section at the part between the counterforts. It should be observed, however, that the thickness of a brick revetment which is to resist the fire of a battering train should not be less than seven or eight feet. It is usual to make the depth of a counterfort equal to the mean breadth of the wall; and to give it greater thickness at the part which joins the wall than at the other extremity.

Counterforts serve in part as props to keep the wall from inclining in consequence of partial compressions in the cement; but chiefly by extending the breadth of the base at intervals they increase, at the places where they are formed, the length of the arm of the lever by which the weight of the wall resists the lateral pressure of the earth. The usual connection of the bricks or stones in the wall with those of the counterforts allows this advantage to be extended in nearly an equal degree to the parts which are situated between the counterforts. But in order that the connection may be more complete, it has been recommended to connect the tails of every two counterforts by a wall curved on the plan, and having the convex side towards the earth which is to be retained. Again, the nearest sides of every two counterforts have occasionally been connected by two or more arches, one above another; by which means the mass of retained earth is in part supported, and the lateral pressure of the whole is diminished.

Revetments in which the counterforts are connected in either of these ways are said to be counter-arched; and it is recommended that arches of the latter kind should be formed in the mass of the parapet above the cordon of the scarp. It is also recommended that the masonry of the arches in the rampart should be but slightly connected with that of the revetment wall; since the greater part of the rampart and parapet will then remain supported by the arches even after the revetment has been demolished by the artillery of the besiegers. When the scarp revetment is carried completely up to the superior slope of the parapet, leaving no exterior slope, it is termed a *full revetment*. When there is an exterior slope left it is termed a *demi-revetment*.

REVIVOR. [SCIRE FACIAS.]

REVOLUTION. This well-known term is applied in astronomy to the manner in which a detached body moves round another, as a planet round the sun; but the motion of connected particles of matter round an axis, such as the diurnal revolution of a planet, is more usually called ROTATION.

In pure mathematics the word revolution is applied to the angle moved over by a line which revolves round a point from any one position to that position again; it is therefore a synonyme for four right angles.

REVOLVERS are fire-arms in which the barrels, or a portion of the barrels, being made to turn round on the cocking of the piece, are brought successively under the hammer, and permit of a rapid succession of discharges from the same piece. Revolvers, or repeating fire-arms, are not an invention of modern times; many of a very ancient date are to be seen in museums and collections of old arms. These are in several points very similar to the most recent improvements, but it was not till the introduction of the percussion cap removed the difficulty of retaining the priming of each charge in its place during the rotation of the chamber, that the revolver could be considered a really serviceable weapon; while at the same time it was not till the great improvement of modern times in cheap accurate machine manufacture that it became practicable to make such instruments in large numbers. For many years revolvers were made with the barrels all in one: five or six barrels being fixed together were made to revolve round a central axis, so as to bring their nipples successively under the hammer.

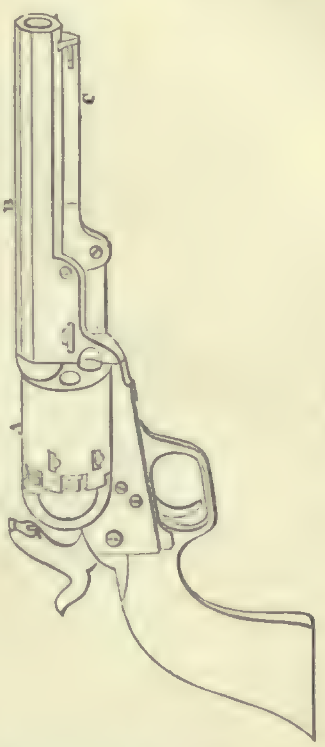


Fig. 1.—A, the chamber; B, the barrel, rifled; C, the lever-ramrod.

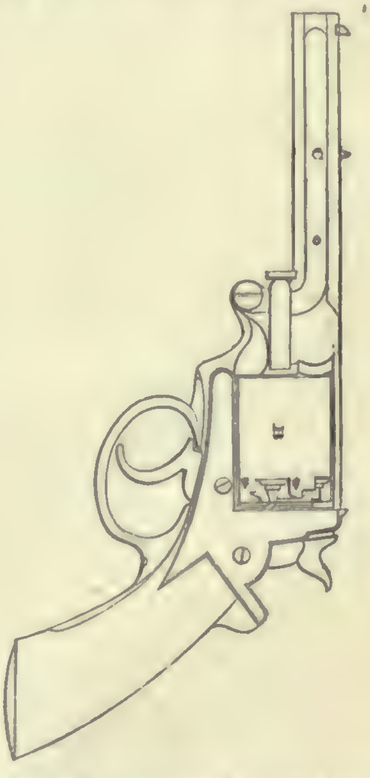

Fig. 2.—A, the barrel; B, cylinder or chamber; C, lever-ramrod.

This, however, even when the bullet was almost unserviceably small, was a heavy clumsy weapon. The adoption of revolving chambers and one barrel overcame this difficulty. *Fig.* 1 shows the outline of Colonel Colt's revolver. This pistol first became generally known in England at the Great Exhibition of 1851, where it excited a good deal of attention. It had been for some years much used in America, and found of great service in bush-fighting and in the backwoods. This undoubtedly set English gunmakers to work in the same direction, for numerous revolving pistols have since been invented in England. There are three sizes of Colt's pistol, the smaller containing five chambers. The bullets may be either spherical or conical, and are made slightly larger than the chamber, into which they are forced by the lever rammer, and fit so tightly that the pistol can be carried in the holster, muzzle downwards, without their being shaken from their places. The chamber is again slightly larger than the barrel, which, being rifled, the bullets on being forced through them take the rifling most effectively.

Fig. 2 represents Adams's revolver, which, since its invention, has received numerous improvements (especially the lever-ramrod, which the earlier pistols were not provided with), and may now be considered the most efficient arm of this description. In Colt's pistol it is necessary to cock the piece with the thumb before each discharge, while Adams's pistol can be fired with only a continuous pull of the trigger; this gives the latter a great advantage in rapidity, an important point with a pistol which is not so much required for long accurate shots as for quick shooting in a mêlée. By another improvement in Adams's pistol, however, we are enabled to cock it for accurate shooting with the trigger or the thumb, when a further slight pull fires the pistol. *Fig.* 3, lock of Adams's revolver, and *fig.* 4, of Colt's revolver, which are taken from 'Straith's Artillery,' by Cook and Hyde, will explain the action of the locks in the two pistols. Revolving or repeating pistols will undoubtedly supersede all others, as being far the most efficient arm; good shooting may be made with them at 100 or 200, and fair even at 300 yards. For cavalry, on board ship, or at close quarters generally, they are a most formidable weapon. Rifles and large firearms have been made on the same principle, and for some purposes they may be very useful; but they labour under the disadvantage of reduced penetrative power and range from the escape of gas at the junction of the chamber and barrel, which has never yet been completely overcome.

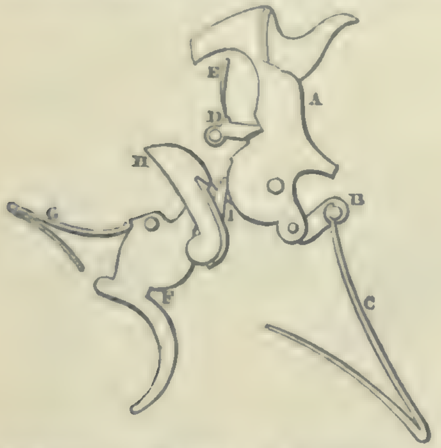

Fig. 3.—A, is the hammer; B, the swivel; C, the main-spring; D, the short sear; E, the short sear spring; F, the trigger; G, the trigger spring; H, the lifter and spring; I, the long sear.—The position of the action is that in which the hammer is down on the nipple.

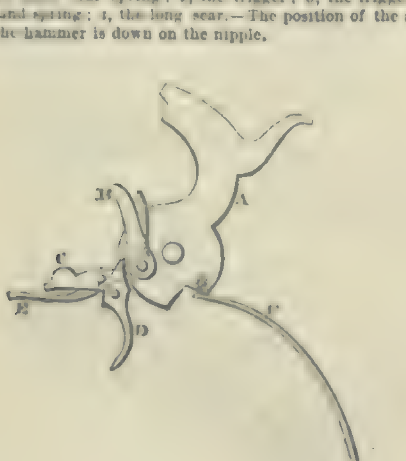

Fig. 4.—A, is the hammer; B, the hand or lifter, which gives motion to the chamber; C, the bolt, which secures the chamber while the hammer falls; D, the trigger; E, the sear and trigger spring; F, the main-spring.

RHAMNIN. A yellow crystalline substance obtained from the buckthorn (*Rhamnus catharticus*), and apparently identical with *chrysorhamnin*.

RHAMNOXANTHIN. A yellow crystalline body found in the seeds and bark of the *Rhamnus frangula*, and of the *Rhamnus catharticus*. It is volatile, slightly soluble in water, and very soluble in alcohol and ether.

RHAPONTICIN. Synonymous with CHRYSOPHANIC ACID.

RHAPSODY (ῥαψῳδία) was a poem sung by a rhapsodist, generally applied to detached parts of the Homeric poems, the Iliad and the Odyssey. But the word rhapsodist properly signifies one who sews or fastens things together; and it was specially applied to those who arranged or are supposed to have arranged the parts of the Homeric poems and of other old poems, so as to make one entire work of them, and who went about from place to place to sing and recite those poems. In modern use the word has an entirely different signification. A rhapsody is a discourse or writing in which the parts have no necessary dependence on each other.

RHEA, one of the divinities of ancient Greece and Rome. Rhea was the daughter of Uranus and Gæa, and the sister and wife of Kronos, by whom she had several children who were successively swallowed by Kronos, till she succeeded in imposing on him a stone for the new-born Zeus. [KRONOS; ZEUS.] Rhea became early identified with the Phrygian mother-goddess Cybele; and also by some of the Greek races, with her daughter DEMETER. Besides the names Rhea, Cybele, &c., she was called "the mother of the gods," "the great mother," &c. The original seat of her worship appears to have been Crete, but it soon spread through Greece. As the great goddess of the eastern nations, her worship was however far more widely extended. The rites of Rhea were in some places mingled with those of Dionysos; and her priests, the Corybantes, leapt, danced, sung, and performed various frenzied orgies in the wilds of Phrygia. As the mother of Jupiter, under the name of Ops, she was worshipped by the Romans from the earliest times. Her festival at Rome was called the Megalesia; her priests were eunuchs, and named Galli. The oak and the lion were sacred to her. In Greek art Rhea is represented wearing a crown with towers, and she carries in her hand a key or a branch. She is usually seated on a throne with lions beside her; or in a car drawn by lions; sometimes she is riding on a lion; in bassi-relievi, &c., she is sometimes seen attended by dancing Corybantes with cymbals.

RHEADIC ACID. [PAPAVERIC ACID.]

RHEIC ACID. [CHRYSOPHANIC ACID.]

RHEIN. [CHRYSOPHANIC ACID.]

RHEOMETER. A number of instruments, &c., used in GALVANISM are named by French physicists *rheometer*, *rheophose*, *rheotrope*, *rheostat*, from the Greek ῥέω, to flow. The words have only been to a limited extent adopted in this country. [GALVANOMETER.]

RHETORIC (ῥητορική) is a Greek word of similar import to the Latin oratory; but a rhetorician is a teacher of or writer on oratory, and an orator is one who practises the art; Demosthenes was an orator, Aristotle was a rhetorician, and Cicero was both.

English writers, in treating of rhetoric, appear generally to consider it the same as oratory, and perhaps it is difficult to make a distinction between them. Cicero's 'Orator,' 'De Oratore,' and 'De Claris Oratoribus,' are always called rhetorical works. Quinctilian ('Inst.,' ii. 14) speaks of persons who translated the Greek word "rhetorice" into Latin by "oratoria" and "oratrix;" but he objects to the use of both these words, and adopts the Greek word, which, he says, Cicero himself employed to designate certain books (probably the two books 'De Inventione') which he had written on this art. An account of Quinctilian's work on the same subject will be found under QUINCTILIANUS, in BIOG. DIV. In the article ORATORY it is stated that the treatise of Aristotle on rhetoric is the oldest extant treatise on this art, and one of the most valuable books preserved from ancient times. The present article seems to furnish a suitable occasion for giving a short account of Aristotle's work.

Aristotle begins by saying that rhetoric is the counterpart (ἀντίστροφος) of logic, and he defines it to be the faculty (δύναμις) of perceiving on any given subject what is best adapted to persuade. He divides rhetoric into three parts: Persuasion (πίστις, or rather πίστεις), Language or Expression (λέξις), and Arrangement (τάξις). His work consists of three books, of which the first and second treat of persuasion, and the third treats of expression and arrangement.

After premising some general remarks on rhetoric, he treats of persuasion as derived from enthymemes (ἐνθυμήματα). Having stated that there are three kinds of persuasion, the deliberative (συμβουλευτικόν), the demonstrative (ἐπιδεικτικόν), and the judicial (δικανικόν), and that, in reference to each of these, persuasion is both special (ἴδιαι) and general (κοιναί), c. 3, he discusses the subject of special persuasion in each kind: touching the deliberative he inquires whether it be useful, c. 4 to 8; touching the demonstrative, whether it be honourable, c. 9; touching the judicial, whether it be just, c. 10 to 15. He concludes the first book by stating and explaining the modes of producing persuasion without the art of rhetoric, c. 16.

In the second book he proceeds to say that, in reference to certain questions, special persuasion must be considered as depending on the character of the speaker, c. 1; and on the passions of the hearers, c. 2 to 13; as also on the general character of the hearers, such as their passions, their moral habits, their different ages and conditions in life, c. 17 to 19. He closes the discussion of special persuasion by viewing it in connection with questions common to the three kinds of persuasion, such as possibility, fact, futurity, and magnitude, c. 19. He then proceeds to persuasion considered generally and indefinitely, of which he mentions two kinds, example (παράδειγμα) and enthymeme (ἐνθύμημα), adding *γνῶμαι* (γνώμη) as included in enthymeme, c. 20 to 26.

He commences the third book with the second part of rhetoric, namely, expression. He states what is necessary to constitute expression, c. 2 to 4; and describes its various forms, c. 5 to 9. He treats of elegance (τὰ ἀστεῖα), c. 10, 11; and represents the different kinds of expression, c. 12.

He then comes to the third part of rhetoric, which is arrangement. This, he says, consists necessarily of two parts, the proposition of any subject, and its confirmation; but there may be four parts, introduction (προοίμιον), proposition (πρόθεσις), confirmation (πίστις), and peroration (ἐπίλογος). He concludes the work by discussing these four parts of arrangement: introduction, c. 14, 15; proposition, c. 16; confirmation, c. 17; peroration, c. 19.

Aristotle's 'Rhetoric' is not only the best treatise upon this subject, but a model of profound thinking and reasoning for the investigation of various other subjects.

RHEUM (*Rhubarb*), *Medical Properties of.* As the particular species which yields the officinal rhubarb, and even the precise place of its growth, are not known, the varieties met with in commerce are here described, without attempting to assign them to any ascertained species. There are six well-marked varieties, namely, Russian or Turkey, Dutch-trimmed, Chinese, Himalayan, English, and French. Of the first sort the greater portion at present comes from St. Petersburg, and is denominated Muscovite, Bokharian, or Siberian rhubarb, while a "part has always formed one of the imports from China into Bokhara, whence passing to Smyrna, it is known in Europe as Turkey rhubarb" (Royle, 'Flora of the Himalaya'), which name it commonly bears in the shops. This kind varies much in size and appearance, the pieces being cylindrical, spherical, flat, or irregular, from two to three inches long, one to three broad, and one to three thick. "The smaller pieces are picked out, being preferred, while the larger pieces and the dust are employed for powdering." Holes are remarked in many of the pieces, of which one occasionally extends entirely through, the others only partially; the former having been made in order to suspend the piece in drying, the others in examining the quality. This kind, and probably the other sorts, is frequently worm-eaten, owing to the ravages of a small beetle, *Sinodendrum pusillum.* (Kirby and Spence, 'Entomology,' i. p. 252.)

Externally the pieces are covered with a bright yellow-coloured powder, which either results from the friction of the pieces during their passage to this country, or from the process of rouncing (that is, shaking in a bag with powdered rhubarb), previous to its exportation. The odour is strong, both of the root and fresh powder, peculiar, somewhat but not pleasantly aromatic. When chewed, it feels gritty, owing to the presence of numerous raphides (or crystals of oxalate of lime, which are present to the amount of between 30 and 40 per cent.); it communicates a bright yellow colour to the saliva, and has a bitter, slightly astringent taste, which to some persons is not unpleasant, as they are in the habit of chewing rhubarb to obtain its tonic effects on the stomach; but this practice is objectionable from the yellow colour it imparts to the teeth and gums.

When the dust which covers the surface is removed, it exhibits a more or less reddish-yellow hue with white lines interspersed, which form beautiful reticulations, best seen on a vertical section, while a transverse section exhibits small star-like spots and depressions of a darker colour. The transverse fracture is uneven, the longitudinal still more so. "The powder of genuine Russian rhubarb is of a bright yellow colour, verging to red, but as met with in the shops it is almost invariably mixed with the powder of English rhubarb," which gives it a much lighter colour.

The analysis of this sort by Hornemann shows it to consist of—

Rhubarberin (or bitter principle of Pfaff)	16
Yellow colouring matter (of Henry)	9
Bitter extractive	14
Oxidized tannin	1
Mucilage	10
A substance extracted from the woody fibre	28
Oxalic acid	1
Woody fibre	14
Moisture, loss, odorous principle	3

Rhubarberin is also called chrysophanic acid, or yellow crystalline granulated matter of rhubarb. According to Schlossberger and Doepping, rhubarb contains three resins: Aporetine, Phaeoretine, and Erythoretine. It is supposed to contain some volatile oil, to which the peculiar odour is due.

The chief chemical distinction between this and English rhubarb is the presence in the latter of a principle termed *rhaponticin*, and 14 per cent. of starch, with a smaller portion of rhubarberin, of yellow colouring matter and extractive: iodine furnishes a ready distinguishing test, for a "decoction of Russian, Dutch-trimmed, or Chinese rhubarb becomes, with a solution of iodine, greenish-blue (iodide of starch); after a few minutes the colour disappears, and no iodine can be detected in the liquor by starch, unless nitric acid be previously added; a decoction of English rhubarb is rendered by a solution of iodine intensely blue (iodide of starch), the colour not completely disappearing by standing." (Pereira.) This difference is clearly dependent on the much greater portion of starch existing in English rhubarb. Inferior rhubarb, or roots cut to resemble rhubarb, and sprinkled over with powdered turmeric, or dyed with it, may be detected by means of boracic acid, or any borates rendered acid, since the colour of genuine rhubarb, or paper dyed with it, is not affected by these re-agents, whereas turmeric-paper is reddened by them. Yellow ochre, with which black and worthless pieces are covered, or which is used to fill the holes in worm-eaten pieces, may be detected by heat, as it burns with a brownish red appearance, and exhibits the characters of a ferruginous earth.

Portions unusually white are occasionally found in the chests of Russian rhubarb, and are presumed to be specimens of *imperial rhubarb;* nothing certain is known of its origin or relative value, but it is assigned to *Rheum leucorrhizum*, Pallas, *R. nanum*, Sievers, *Rheum tataricum*, Linn.

2. Dutch-trimmed rhubarb, called also by some writers Persian rhubarb, and Batavian, occurs in flat or round pieces, and is not much different in appearance from the preceding, but it reaches Europe through Canton and Singapore. It is said to be very liable to the attacks of a small coleopterous insect, *Anobium boleti*, and that the holes so made are stopped with yellow ochre.

3. Chinese or East Indian rhubarb, termed in commerce *half trimmed or untrimmed* rhubarb, rarely presents an angular character, but occurs in rounds or flats. "The best pieces are heavier and more compact than those of the Russian kind, and the odour is much less powerful and less aromatic."

4. Himalayan rhubarb is not known as a commercial article in this country, nor is it even an article of large consumption in India, where it sells for only one-tenth of the best rhubarb, resembling in quality the Russian, and which is found in India. The finest Russian rhubarb might be introduced and cultivated in the territories of the East India Company, or, as Dr. Royle observes, "a trade in rhubarb with Tibet or Western Mongolia might be established by means of the Tartars who resort to the hill fairs. This trade might easily be encouraged by the government purchasing all the rhubarb it requires, which might thus be employed for hospital use after crossing the frontiers, instead of, as now, after making a journey of 20,000 miles, or nearly the circuit of the globe." ('Flora of the Himalaya.')

5. English rhubarb occurs in two states, "*dressed or trimmed*, so as to resemble the Russian kind, and *stick* rhubarb. The first is grown at Banbury in Oxfordshire, and is frequently used for the show-bottles in druggists' windows, and often sold in the streets of London for *Turkey rhubarb*, by persons dressed up as Turks. Stick rhubarb is sold in the herb shops, and is in long pieces."

6. French rhubarb is not brought into this country.

What is termed *Monk's rhubarb* is not the produce of any species of *rheum*, but of the *Rumex alpinus*, which grows in Switzerland, Germany, and Mount Taurus, and is more astringent than purgative: it is mostly used by the monks of the Alps, or to adulterate the other sorts.

Large importations of rhubarb are made into this country, partly from Russia, but much more from the East Indies; but the greater part is for re-exportation. The quantity retained for home consumption scarcely constitutes one-fourth of the entire amount.

Rhubarb presents the peculiarity of producing two opposite effects, according to the dose exhibited. In small doses it is tonic and astringent, in large doses purgative, but generally followed by constipation. It is moreover somewhat heating, and therefore unfit for the early stage of inflammatory diseases; on the other hand, its tonic properties render it eminently proper in the later stages of these diseases. In debility of the digestive organs, alone, or better in conjunction with other agents, it is a most valuable remedy; but it is very improper in the form of powder for very young children, as the insoluble woody fibre irritates their delicate stomachs, and contributes to produce that state of irritation under which so many young children sink who are overdosed with domestic medicines. Dr. Reid, from large experience at a public dispensary, stated it as his deliberate opinion, that half the children which died in London under two years of age were killed by mothers and nurses dosing them with rhubarb and magnesia. A more rational proceeding is to regulate the diet of tender infants, especially of such as are not suckled by the mother or a wet nurse; above all, to avoid giving them stimulating drinks or raw fruits. Where any form of gentle aperient and antacid is really necessary for children or infants, an infusion of rhubarb made with cold water, to which carbonate of soda is added, answers well. Compound rhubarb pill, a very commonly-used aperient, is hurtful to persons prone to suffer from piles. But an unobjectionable and very mildly acting aperient pill can be made with equal parts of extract of rhubarb, extract of jalap, and extract of taraxacum, with a very little jalapina, and some drops of any volatile oil, such as dill, carraway, or cloves.

Several species of rheum, and garden varieties of them, are cultivated for the sake of the petioles of the leaves, which are much used to make tarts in spring. The cooling and gently aperient properties of these render them grateful and beneficial to most persons; but individuals prone to calculous complaints should carefully avoid them, and all vegetables which owe their acidity to oxalic acid, as the formation of the oxalate of lime, or mulberry calculus, may be the consequence of indulgence. This observation applies equally to the species of Rumex which are used as sorrel. [CICER ARIETINUM.] (Pereira's 'Mat. Med.')

RHEUMATISM (from ῥευματισμὸς, "a defluxion"). It is probable that this term was originally adopted during the prevalence of the doctrines of the humoral pathology, when every disease attended with swelling was attributed to the flow of some morbid humour to the part affected. Before the year 1642, rheumatism and gout were usually described as one disease, under the name of arthritis; the distinction between the two is said to have been first accurately made by Bellonius, a physician who suffered much from rheumatism.

Acute rheumatism, called also rheumatic fever, has been so well described by Sydenham, that we make use of his own words: "This disease," he observes, "happens at any time, but especially in autumn, and chiefly affects such as are in the prime of life. It is generally occasioned by exposing the body to the cold air immediately after having heated it by violent exercise or some other way. It begins with chilliness and shivering, which are soon succeeded by heat, restlessness, thirst, and the other concomitants of fever. In a day or two, and sometimes sooner, there arises an acute pain in some or other of the limbs, especially in the wrists, shoulders, knees; which shifting between whiles, affects these parts alternately, leaving a redness and swelling in the part last affected. In the beginning of the illness the fever and the above-mentioned symptoms do sometimes come together, but the fever goes off gradually, while the pain continues and sometimes increases." Acute rheumatism varies considerably in intensity and duration; the patient may have great fever, and severe pain in nearly every joint, so as to render him perfectly helpless; or the fever may be slight, and the local inflammation limited to one or two joints. There is not always a relation between the severity of the local symptoms and the constitutional disturbance. The duration of this disease is much the same under any mode of treatment; it may be terminated in a few days, or may endure as many months; in nearly every case the general symptoms cease before the local inflammation is stopped. Acute rheumatism simply, is seldom if ever a fatal disease, but complicated with pericarditis, endocarditis, or pleurisy, it is highly dangerous. It behoves us therefore in every case of rheumatism to be on our guard against these complications; they are so frequent and come on so insidiously, that a recourse to the aid of the stethescope should never be neglected. [HEART, DISEASES OF THE.]

With respect to what is called chronic rheumatism, it may be either a continuance of acute rheumatism in a milder form, or may originate in this chronic, or, more properly speaking, subacute character. In either case all the characters of acute rheumatism are present, but in a less violent degree; thus, there is a quickened pulse, some increased heat of skin, a furred tongue, and loss of appetite and sleep, the febrile action undermines the general health, while the local inflammation, although indolent, disorganises the joints. This state of things may endure for an indefinite period, or the febrile symptoms may after a time disappear and the morbid action in the joints cease, not however without leaving behind them such ravages as require a special local treatment. Dr. Elliotson has distinguished chronic rheumatism into hot and cold: in the former, the joints affected are above the natural temperature of the other parts of the body, and are relieved by the application of cold; in the latter, the contrary is the case. Whether the pain of the joints is relieved most by hot or by cold applications, it is generally aggravated in cold moist weather, and diminished during an opposite condition of the atmosphere. The only diseases with which rheumatism can be confounded are gout and periostitis; for its distinction from the former of which see GOUT.

The term rheumatic, whether properly or not, has been applied to various affections which have very little resemblance to one another, except in being attended with pain. Thus a class of cases has been called rheumatic gout. This is a disease partaking of the characters both of gout and rheumatism. It may be rheumatism attacking the small joints, or it may be gout extending to the large; in either case the distinction is not of much importance, as the treatment is the same.

When rheumatism is seated in the back, it is called lumbago, from *lumbus*, the loin; when in the back of the neck, the patient is said to have a stiff neck, or a "crick in the neck;" when in the head, one half only is usually attacked, and it is called hemicrania. When the pain occupies the more fleshy parts of the limbs, as the muscles or their aponeuroses, the term rheumatalgia is sometimes made use of. In this last-named affection there is neither redness nor swelling, and pain is experienced only when the muscles of the part affected are called into action. Many persons believe that the nerves themselves may be affected with rheumatism, and refer to sciatica and hemicrania as examples. In these cases the pain is generally of an intermittent character. This intermittence of pain is not peculiar to nervous rheumatism, but is met with also when the aponeuroses of muscles are the seat of the disease, as in hemicrania. "It usually attacks one half of the organ (the head), and the pain generally comes on in the evening about six o'clock, and continues very violently for a few hours. Occasionally when it is intermittent in this way, the parts are hot, swollen, and throb, and the eyes water; but in other cases this is not felt." (Elliotson.) Many physicians of eminence deny that the above-named affections are rheumatic, and consider them to be of nervous origin; hemicrania and lumbago they call neuralgia, and rheumatalgia they designate by the term myositis. From this contrariety of opinion we may conclude that little is known respecting the structures actually affected in these varieties of rheumatism; of the morbid changes which they undergo we are likewise in equal ignorance. In the true or articular rheumatism it is the synovial membrane lining the cavity of the joints and the fibrous tissues external to them that principally suffer. The respective degree in which each of these structures is implicated is not the same in every case. Thus, in one case, we shall find the joints distended with fluid, the fluctuation of which is very perceptible to the hand; while in another there shall be swelling, but it will be more diffused and without fluctuation, showing that little or no effusion has taken place into the joint, but that the swelling results from the inflammation of parts external to it. This difference has led some persons to speak of rheumatism as fibrous and synovial; but inasmuch as it is not always easy to determine to which variety the case under examination may belong, and is besides of no practical importance, the distinction is not usually regarded. The fluid which is found in the joints may be either gelatinous or purulent, according to the severity of the inflammation. The synovial membranes which line them are red and thickened; the ligaments external to the joints are thickened and rigid, the limbs frequently contracted, and the muscles wasted. In rheumatic gout there is often found a deposit of lithate of soda in the joints affected,—a proof that, in many cases at least, this disease partakes more of the character of gout than of rheumatism. The appearances presented in the heart and its coverings, where this organ has been attacked, have already been described in the article HEART, DISEASES OF THE.

Causes of Rheumatism.—Among the causes which predispose to rheumatism must be placed an hereditary tendency and the age and temperament of the individual. The period of life most subject to acute rheumatism is from puberty to 35 years of age, and persons of full plethoric habit are said to be more liable to its attacks than those of an opposite temperament. It is supposed by many, among whom may be cited the names of M. Andral ('Anatomie Pathologique'), M. C. Roche ('Dictionnaire de Médécine et de Chirurgie), and Dr. Barlow ('Cyclopædia of Practical Medicine), that an absolute or relative condition of plethora is essential to the development of rheumatism; and the blood, according to these authorities, may be either excessive in quantity or altered in quality. "There are some individuals," observes M. Andral, "who naturally make a greater quantity of blood than others. When the bloodvessels contain a greater proportion of the nutritive fluid than is necessary to supply the demands of the different organs, the superabundant quantity becomes a permanent source of excitation to the solids, and at the same time the blood has a remarkable tendency to accumulate in different organs; so that in such a case the whole system is in a general state of excitation, and some of the organs may become the seat of local congestion of various degrees of duration and intensity." In applying these doctrines to the disease we are considering, he observes, "If we mark the symptoms and progress of acute rheumatism, we find that very often a well-marked febrile action, with a strong reaction, but without any symptom whatever of local affection, precedes the pain. In a word, there is first an inflammatory fever, and then rheumatism. Next observe the extreme mobility of the rheumatic pains. They run along, in a manner, wherever the blood is distributed; the application of leeches often removes the pain from one part, but it soon shifts to another, and not unfrequently it quits the articulating tissues and fixes on different internal organs, producing, by the derangement of their functions, symptoms more or less severe. It often happens that bleeding from a large orifice puts an end to the disease, as if, by diminishing the mass of blood, it proportionally diminished the stimulus that promoted all these shifting irritations." It is then, when the body is in this predisposed condition, from any of the before-mentioned causes, that exposure to a continued draught of cold air or a shower of rain becomes the immediate exciting cause of an attack of rheumatism.

Whatever may be the general condition of plethora, which has been observed in certain cases, there can be no doubt that rheumatism will only come on in certain conditions of the blood. It has been observed that during rheumatism considerable quantities of lithic acid and lithate of ammonia occur in the urine, and there seems to be little doubt that in all cases of rheumatism there is an accumulation in the blood of some substance which acts as a *materies morbi*. This substance is not identified, but between the substances of the food on the one hand and the excretions of the skin and kidneys on the other, there is a wide field for the production of abnormal products, which may be the cause of disease. It has been supposed by Dr. Todd and others, that the real *materies morbi* is lactic acid in the blood. This, however, is at present problematical, but it is very certain that an abnormal condition of the blood is the most general antecedent of rheumatic disease.

Cold has been often supposed to be an absolute cause of rheumatism. But this is certainly not the case, as out of half a dozen men exposed to the same degree of cold only one may have rheumatism. This disease is also not more prevalent in hot climates, as compared with cold ones, than could be accounted for on the supposition of other causes than cold producing the disease. That cold is an exciting cause when the body is already predisposed there can be no doubt.

Treatment of rheumatism.—Dr. Haygarth, on being asked what was the best remedy for acute rheumatism, is said to have replied, "Six weeks." The sagacity of this reply can be best estimated when the literature of acute rheumatism has been gone through. Blood letting, calomel, opium, bark, alkalies, iodide of potassium, colchicum, aconite digitalis, tartarised antimony, nitrate of potash, brandy and water, infinitesimal doses,—have all had their advocates, and in every set of cured cases reported the average duration will be found to be about six weeks. It is not, however, to be supposed that the treatment of acute rheumatism is one of indifference. According to the severity of the symptoms and the temperament of the individual the judicious physician will apply his treatment. The symptoms of disease of the heart should be watched for with anxiety, and where detected the treatment must be modified accordingly. Blood-letting is now seldom had recourse to. Opium to alleviate great pain and alkalies to act on the kidneys and bowels, and modify the condition of the blood, are recommended by all rational practitioners. Dr. Bennett, of Edinbergh, speaks highly of nitrate of potass. Local bleeding is occasionally of service. In chronic rheumatism liniments over the inflamed joints, with iodide of potassium, and bark, and guaiacum, with other tonics and stimulants, are valuable remedies. Cold bathing and mineral waters are adapted for some cases.

According to Dr. Elliotson, whether rheumatism be acute or chronic, the treatment should be exactly the same: "You have only to make two distinctions,—to ascertain whether it is the inflammatory form of the disease: whether the parts are hotter than they should be, and heat does harm; or whether the parts are cooler than they should be, and heat does good." In the one case he recommends antiphlogistic measures, and in the other stimulants; under the antiphlogistic measures, he comprehends bleeding and the administration of colchicum, the latter to be continued till it purges the patient. During the whole time of the treatment cold, lotions are applied to the inflamed joints. In the chronic form of rheumatism the joints are kept hot with flannels and rubbed with stimulating ointments and liniments, while the ammoniated tincture of guaiacum, beginning with half-dram doses, is given three times a day. Dr. Elliotson also considers that mercury is occasionally useful in both kinds of rheumatism. Lumbago and sciatica are most successfully treated by cupping the loins and the parts over the course of the great sciatic nerve, followed by the application of blisters to the same regions, and a general antiphlogistic regimen. In hemicrania great relief is frequently obtained by the application of heat to the part affected, as in wrapping up the head in flannel. Should the pain evince a tendency to return every evening, a large dose of a narcotic should be administered just previous to the paroxysm, and if not relieved in two or three hours, a similar dose must be repeated; we are informed that one grain of stramonium for an adult frequently acts like a charm in this affection. In rheumatalgia, when the parts are not hot, and the pain is not increased by heat, acupuncture and shampooing have been found of great service.

Where the joints are stiff and contracted, from long-continued inflammation, warm bathing, combined with frequent and persevering exercise of them, have been attended with the most signal success.

RHEUMIN. [CHRYSOPHANIC ACID.]

RHODALLINE. [THIOSINAMINE.]

RHODANHYDRIC ACID. Synonymous with HYDROSULPHOCYANIC ACID.

RHODANOGEN. Synonymous with SULPHOCYANOGEN.

RHODEORETIC ACID. [CONVOLVULIC ACID.]

RHODEORETIN. [CONVOLVULIN.]

RHODEORETINOL. [CONVOLVULINOLIC ACID.]

RHODEORETINOLIC ACID. [CONVOLVULINOLIC ACID.]

RHODIUM (Ro), a metal discovered by the late Dr. Wollaston in 1803, and named from *rhodon* (ῥόδον, a rose), on account of the colour of one of its solutions. This metal exists in combination with platinum. According to the analysis of Berzelius, the ore of Columbia contains nearly three and a half per cent., and that of Siberia only 1·15 per cent of rhodium. When the greater part of the platinum and palladium have been separated from the solution of the native grains, by the addition of chloride of ammonium and cyanide of mercury, a plate of iron is to be immersed in the residual solution, and by this the rhodium, with small quantities of platinum, copper, and lead, is thrown down in the metallic state. In order to render the rhodium pure, it is first digested in dilute nitric acid, which dissolves the copper and lead, and the rhodium and platinum are then to be dissolved in aqua regia mixed with some common salt, and the solution is to be evaporated to dryness. By this operation there are obtained the double chloride of platinum and sodium, and rhodium and sodium. The former is to be dissolved in alcohol, and the latter afterwards in water, when a plate of zinc immersed in the solution precipitates the rhodium in the metallic state. The metal thus procured is in the state of a black powder, and requires the strongest heat of a wind-furnace, or better the oxyhydrogen blowpipe, for fusion. It is less fusible than platinum.

Rhodium is white; has a metallic lustre; is extremely hard; specific gravity 12·1; and is ductile and malleable. It is not dissolved by any acid or by aqua regia, except when it is alloyed by other metals; and this circumstance accounts for its being dissolved, when alloyed with platinum, in the native grains of this metal. It suffers no change by exposure to air, either dry or moist. The equivalent of rhodium is 52·16.

Oxygen and Rhodium form two compounds. They cannot be made to combine by direct action. The protoxide has not yet been obtained in a state of purity. When finely-divided rhodium, mixed with potash and a little nitre, is heated to redness in a silver crucible, the metal is oxidized, and becomes of a brown colour, and is mixed with potash; the mass is to be washed with water and then treated with hydrochloric acid, by which hydrated peroxide of rhodium is left, of a greenish gray colour. It contains Ro_2O_3. When this peroxide is heated, it becomes black, and is then probably converted into protoxide.

Chlorine and Rhodium probably unite in three proportions, but the perchloride (Ro_2Cl_3) only has been hitherto obtained in a separate state. It was procured by Berzelius by adding silico-hydrofluoric acid to a solution of the chloride of potassium and rhodium, as long as the double fluoride of potassium and silicon was generated, after which the filtered liquor was evaporated to dryness, and the residue redissolved in water. The remaining perchloride thus obtained has a dark brown colour, and when heated to redness, chlorine is evolved and metallic rhodium obtained. The aqueous solution of this salt is a fine rose-red colour, whence the name of the metal which it contains.

This salt forms double compounds, called rhodio-chlorides, with the chloride of potassium and of sodium.

Sulphur and Rhodium may be made to combine by heating them together, the metal being in a state of minute division. The *protosulphide* ($Ro\,S$) formed fuses at a white heat without decomposition, has a bluish-gray colour, a metallic lustre, and by the action of nitric acid is converted into sulphate of rhodium. *Sesqui-sulphide* of rhodium (Ro_2S_3) may be formed by heating the ammonio-chloride of the metal with sulphur, or by heating its solution with sulphide of potassium.

Salts of Rhodium.—The salts of the peroxide only have been formed. Their general properties are but little known.

Nitrate of Rhodium is obtained by dissolving the peroxide in the acid: it is of a deep red colour, and uncrystallizable.

Sulphate of Rhodium is procured, as already mentioned, by acting upon the sulphide with nitric acid. The solution is of a deep red colour, and does not yield crystals. When the caustic alkalies are added to the solution of this or the other soluble salts of rhodium, a precipitate of the hydrated sesqui-oxide of a greenish-yellow colour is obtained after some time; the alkaline carbonates produce no effect, nor does sulphurous acid, nor the ferro-cyanide of potassium. Hydro-sulphuric acid throws down sulphide of rhodium; but the hydrosulphates of ammonia and potash produce no immediate precipitate.

Alloys of Rhodium.—When combined with steel to the amount of only two per cent., it gives the steel great hardness without causing it to crack under the hammer. Dr. Wollaston examined several of its alloys, and, on account of its hardness, he suggested its employment for the nibs of metallic pens; to which purpose it has been applied successfully. It has not been combined with mercury.

RHODIZONIC ACID ($3HO, C_7O_7$). In the preparation of POTASSIUM, a combination of that element with carbonic oxide is formed in considerable quantities. The composition of this compound is not at present very well understood. In the presence of moisture, however, it assimilates water, and is converted into the potash salt of an acid termed *rhodizonic* (ῥόδον, a "rose"), from the red colour of its salts. Rhodizonate of potash forms oblique rhomboidal prisms of a bluish-green metallic appearance. It is insoluble in alcohol or ether, but readily soluble in water, yielding a deep red solution; it is inodorous, tasteless, and tolerably permanent in the air. On the addition of sulphuric acid to the potash salt, rhodizonic acid is set free, and may be obtained in bluish-black crystals.

Croconic acid ($2HO, C_{10}O_8$), so called from the yellow colour of its salts, is a product of the action of a temperature of 212° Fahr. upon rhodizonate of potash. From the potash salt the acid may be set free by sulphuric acid, or, better, *hydrofluosilicic acid*. It crystallizes in transparent, orange-yellow, inodorous, astringent, and very acid crystals.

It is soluble in water or alcohol, and forms neutral or acid salts with bases.

RHODOTANNIC ACID. [Tannic Acids.]

RHOMB, RHOMBUS, RHOMBOID. These terms have been used in various significations by different writers, and the second and third have been sometimes distinguished from each other in meaning. It is not worth while to do more than state, that when either of them is now used, it signifies an equilateral oblique parallelogram. The Latin dictionaries define rhomboides to be a parallelogram, and rhombus an equilateral parallelogram.

RHUBARB. [Rheum.]

RHUBARBARIC ACID. [Chrysophanic Acid.]

RHUBARBARIN. [Chrysophanic Acid.]

RHUMB. [Rumb.]

RHYME. Johnson derives this word from the Greek *rhythmus* (ῥυθμός). Others derive it from the Swedish and Danish *rim*, the Dutch *rym*, and the German *reim*. All the principal European nations use the same word to signify the same thing. Thus, the French have *rime*, the Italians *rima*, and the Spaniards *rima*. The Greek and Roman poets did not use rhyme, and the word rythmus was applied by both, in its poetical meaning, to the metrical arrangement of syllables, and not to the correspondence of sound in their terminations. Rhyme was not used either by the Celtic or by the early Scandinavian nations. Thus the Irish and Erse poems on which Macpherson founded his 'Poems of Ossian' are without rhymes, as is also the Scandinavian poem of the 'Lodbrokar Quida' (Lodbroc's Death-Song). Rhyme, as an accompaniment of verse, cannot be traced farther back among European nations than to the *rymours* of Normandy, the *troubadours* of Provence, the *minnesingers* of Germany, and the monks, who, after the fall of the Roman empire, added rhyming terminations to the Latin metres which were chanted or sung in the church service. Rhyme was early employed by the Italian poets. The 'Divina Commedia' of Dante, the oldest of the great Italian poems, is in alternate rhymes. The early Spanish ballads sometimes have rhymes, sometimes only assonances [Assonance], and sometimes, as in the old Spanish romance of 'The Cid,' are without either rhyme or assonance. The early Anglo-Saxon poetry is without rhyme, but it is sometimes used in the later. All the old English poetry has rhymes, which are rude and imperfect, like the versification, but they are obviously an adjunct to the verse which could not be omitted.

Perfect rhymes arise from the identity of sound with which different words terminate—the identity, not the similarity. In monosyllables, or words which have the accent on the last syllable, to constitute a perfect rhyme it is necessary that the sound of the last accented vowel and of any letters which may follow it should be exactly the same as those of the word with which it rhymes. The sounds which precede the last accented vowel must be different in the two words. The spelling is of no consequence; the rhyme is in the sounds, not in the conventional signs by which the sounds are expressed. Thus *no* rhymes to *so*, but not to *do*, which rhymes to *too* or *two*; *great* rhymes to *hate*, but not to *heat*, which rhymes to *feet*; and so on. If the sounds of the last vowels, or of any of the following consonants, differ in any degree, however small, the rhyme is so far imperfect; thus, *love* and *move* form an imperfect rhyme, the sound of the *o* in love being not only shorter than that of the *o* in move, but to a certain extent different. These monosyllable or last-syllable rhymes are called male rhymes.

Another class of rhymes is formed from words in which the accent is on the last syllable but one. In this class it is requisite that the sounds of the last vowel in the last syllable but one and of all the following letters should be the same as those with which they rhyme. Thus, *desiring* and *respiring*, *descended* and *extended*, are perfect rhymes of this class. These are called female rhymes.

The principle of rhyming, once understood, the application is easy in all cases. Thus, if the accent is on the last syllable but two, the sound of the last vowel of the last syllable but two, and of all the following letters, must be the same. Thus, *sensible* and *extensible* are perfect rhymes of this class, but *dissolute* and *resolute* are imperfect rhymes, the vowels in the last syllable but two of both words having different sounds.

The same principle of rhyming applies to all the modern languages, as well as to the English. Imperfect rhymes are more or less freely used in all of them, according to circumstances. The English and German languages, which abound in consonants, and have for the most part consonant terminations, are more deficient in rhymes than the Italian and Spanish, which abound in vowels, and have for the most part vowel terminations.

RHYTHM (Ῥυθμός, *measure, proportion*), in Music, is *Time*; first, in a limited sense, as in the relative proportions of notes in a single bar; and, secondly, in a more general sense, as in the relative proportion of a number of bars in any given portion of a composition, as in either half of a minuet or of a march. Rhythm is the most important constituent of music; without it inarticulate sounds are unproductive of any musical effect. [Music.] In melody, that is, a succession of measured sounds, notes are the component parts of a bar, and bars are the component parts of a strain, or musical period, or phrase. The due relative proportion of all these is absolutely necessary in the formation of a good musical composition; without it, says one who seems to have possessed a most discriminating and refined taste in the art,—

> "How sour sweet music is
> When time is broke, and no proportion kept!"
> *Richard II.*

Musical *Rhythm*, in its limited sense, divides a bar into 2, 4, 8, &c. or 3, 6, 12, &c. equal parts; the former is *binary* measure, the latter *ternary*. In its more general sense it divides a strain, a phrase, or by whatever name the subdivisions of a composition may be designated, into equal portions of 2 or 4, &c. or 3, 6, &c. bars, or measures; and some writers have admitted a rhythmus of five bars. An intimate acquaintance with the nature of rhythm, whether considered in its relation to music or poetry, is essential to the accomplished composer; without a full knowledge of this he is perplexed by doubts, and guilty of errors which have too often brought reproaches on the art, when they ought to have fallen on the pseudo-artist. Our limits however will not allow us to extend this article; and we refer the reader, particularly the professional one, to a learned and able disquisition on rhythm in Burney's 'Hist.', vol. i., p. 71; to Callcott's 'Musical Grammar,' where much practical information from Riepel and other German writers is to be found; to Kollman on 'Harmony;' and more especially to Reicha's 'Traité de Mélodie.' [Phrase; Time.]

RIBBON MANUFACTURE. Ribbon, or riband, signifies a long narrow web of silk worn for ornament or use. Ribbons of linen, worsted, gold, or silver thread were formerly included in the term, but the designation is now generally confined to those made of silk. Ribbon, in German, is *band*; Danish, *baand*; Swedish, *band*; French, *ruban*; Dutch, *lint*; Russian, *lenta*; Spanish, *cinta*; Portuguese, *fita di seta*, from the Latin *vitta*; Italian, *del nastro, fettuccia*.

Silk was early wrought into ribbons. They formed a branch of the silk manufacture during its progress from Greece to Sicily, and from thence to Italy and Spain; but the ribbon trade seems first to have assumed distinct importance in France. Paris, Tours, Lyon, and Avignon were the chief seats of the trade; the two last cities were rivals until the year 1723, when, partly owing to the regulations which the jealous Lyonnese had prevailed upon the government to make in their favour, and partly to a plague of two years' continuance, the trade of Avignon was ruined, and in great measure transferred to Lyon. Figured ribbons were made chiefly at Paris. About the year 1680, there was a rage for ribbons *gauffrés*, or embossed, on account of their novelty. The stamping was performed by hot plates of steel, on which a pattern was engraved, being applied successively along the piece. A master-weaver named Chandelier, tired of this slow process, contrived a machine which would save his labour. He engraved his figures on two cylinders of steel, between which, when heated, the ribbon was compressed and drawn rapidly by simple machinery: so that a piece of ribbon was embossed in less time than his brother workmen consumed over a single ell. The ribbons called *double lisse* (double warp), which were considered the richest and best, were made at Tours. Before the revocation of the Edict of Nantes, the ribbon-looms of Tours amounted to 3000; but this measure, which banished the Protestants, banished with them their trade, and both Tours and Lyon suffered severely from its effects; the trade of Lyon afterwards revived. Savary, inspector-general of French manufactures, in his 'Dictionary,' published in 1723, says, that the trade in ribbons was much diminished in his time; but it became very large in the next generation. In the enumeration of the different kinds of ribbon, a double satin is mentioned, that is, one alike on both sides in texture, although sometimes of different colours.

Coventry is the head-quarters of the English ribbon-trade. The weaving is done on several systems. The *undertaking system* applies now only to the single-hand trade in the country districts—Bedworth, Nuneaton, Hartshill, &c.: it is the same that the French have employed since the days of Colbert. According to this plan, the undertaker, or master-weaver, receives the silk dyed in the hank from the manufacturer, and returns it in finished ribbons to his order; all the intermediate operations being included in the price of weaving, two-thirds of which are paid to the journey-hand for his labour. Three-fourths of the single-hand weavers are women, and nearly one-half of the remainder are youths under 20. Boys and girls are considered competent weavers at 16 or 17. On the *journey-work system*, by which the great proportion of the engine looms in Coventry and its neighbourhood are worked, the manufacturer gives the silk, already wound and warped, to the first-hand journeyman, who is also the owner of the looms. The shoot-silk is given in hank, for the winding of which the manufacturer allows 1*d.* per oz., besides the price for weaving, in which is included the filling, or the winding of the shoot on the small revolving pins within the shuttles. About one-fourth of the hands employed on this system are women. On the *hand-factory system* the manufacturer is the owner of the looms. The journey-hands work them in the loom-shop of the proprietor, who gets the winding and warping done at his own charge, leaving only the filling to the weaver, which is included in the price of his work, and is often done by very young children. This plan is adopted by many manufacturers of small capital, who, by personally superintending the work, and becoming in fact their own undertakers, are enabled to economise to the utmost in the cost of production; while their hands are all reduced to the lowest condition of the weaver—the journey-hand, who supplies the labour, and has no property in the looms. A modern innovation, encouraged by the last system, is the employment of two hands to a loom, the one being occupied uninterruptedly in shooting down, or passing the shuttle, and making the ribbon; the other in picking up, or fastening broken threads, picking out knots, &c. On the *steam-factory system*, the manufacturer gets every preparatory process done, and by the steam-power one-half of the weaving process itself—the shooting down: all that is left for the weaver being the picking up and superintendence. The profitable application of steam-power to silk-weaving was long considered to be almost impossible, so large a portion of time being consumed in the handling and trimming of the silk, in proportion to the time that the loom is in motion, and a consequent waste of power. A small factory was built in Coventry in 1831, for the purpose of making the experiment on ribbons. It was burnt, however, during a disturbance relating to prices; but within a few years there were numerous steam-factories at work at Congleton, Leek, Derby, and other places, which made large quantities of plain ribbons, chiefly black sarsenets. The Coventry manufacturers had more difficulties to contend against, but ultimately they introduced steam-power under certain circumstances. In these power ribbon-looms, each loom is tended by one pair of hands, which pick up and keep the machinery in order. The gain consists, not in a more rapid motion of the shuttles, the delicacy of the materials not allowing of this, but in the shooting down being seldom interrupted during the picking up, as in hand-loom weaving; in the greater regularity of the fabric, the same number of shoots to the inch being uniformly maintained; and also in the addition of more shuttles, for which one workman suffices, the loom being so constructed as to enable him to reach from the front over the batten to the warps behind.

Italian organzine silk, either thrown in Italy or in England from Italian raw silk (and principally the last), is used for the warp of the best English ribbons: Bengal and China organzine for inferior qualities. China, Bengal, and Broussa (a Turkish silk, produced at Bursa or Brousse, in Asia Minor) singles, all English thrown, are used largely for shoot. Bengal cannot be used for fine colours. Marabout is used for gauzes. Much of the silk-throwing and dyeing is done at Coventry. When the silk is dyed *soft*,—that is, when the gum is boiled off,—it comes back from the dyer with a loss of four ounces out of sixteen in weight; when dyed *single*, the gum being partly retained, it loses only one ounce and a half in sixteen. Inferior warp silk dyed black, and of dark colours, is sometimes *weighted* by an additional quantity of dye, or by a mixture of sugar to increase its apparent substance.

The fineness of the silk is determined by the number of warp lengths, measuring 72 yards, in the ounce; fine warp silk, for instance, runs about eight score threads to the ounce of that length. One ounce in twenty is allowed for waste in the manufacture of the silk into ribbons; for all over that quantity the undertaker, or journey-hand, is accountable. If the warp and shoot are delivered ready wound, a quarter of an ounce in twenty is allowed. The preparation of the silk by winding it from the hanks on bobbins, and then again winding it off from a sufficient number of these bobbins at once round a large revolving perpendicular reel, called the warping-frame, until the requisite length is obtained for the piece of silk or ribbon that is to be manufactured, and likewise the weaving process itself, are the same for the making of ribbons and for broad silk.

The weaving of ribbons is conducted in many different ways. The *single-hand ribbon-loom* differs in no essential respect from that used for any other fabric, except that its size and strength are proportional to the lighter material.

The Dutch *engine-loom* was introduced about ninety years ago. In this loom, instead of one piece of ribbon only, several are woven at once, four of the broadest width, or as many as twenty-four of the narrowest. Each warp has a separate shuttle. The batten extends across the whole width of the loom; the shuttles slide within grooves made in the batten; the driver is worked horizontally backwards and forwards by a handle. At each motion, the shuttles are propelled by the cross-bars of the driver across their proper warps in the corresponding direction. The loom is worked by the hands, and with treadles for the feet, like the single hand. The stroke of the batten is made with more precision than in the single-hand loom, by the interposition of blocks of wood fastened to the framework in front, which resist the batten at the proper point. The impulse of this stroke pushes back the finished ribbon, which is hung with a weight attached to the end over a pulley at the top of the frame, or wound on a roller, just enough to draw forwards the warp, which is similarly hung over a pulley, in order to receive the shuttle at the same point. Each warp has a separate reed or *sleigh* attached to a horizontal roller, over which it passes on descending from the pulley. The sleigh is an instrument like a comb, for keeping the threads separate. There are corresponding sleighs in the batten.

The *à-la-bar*, or *bar-loom*, was invented and introduced into St. Etienne by two Swiss brothers about eighty years ago. It has largely contributed to the prosperity of the place, but the brothers died in poverty and neglect. It is a hand power-loom worked by means of a long transverse handle or bar, which extends along the front of the loom, and is connected with wheels on each side, which communicate the motion. The shuttles are driven by means of a rack and pinion across the warps. The advantage of the bar-loom consists in the saving of labour by the intervention of mechanical means, instead of applying manual power direct to the usual operations of weaving. From twenty-eight to thirty of the narrowest and from six to eight pieces of the broadest width are made at once: about eight ells of the former per day, and from three to four of the latter.

Several hand power-looms for ribbons have been contrived and adopted, in all of which the requisite movements are performed by a combination of levers, springs, cranks, and wheels.

Figures on ribbons, as in other fabrics, are chiefly formed by omitting the regular crossing of the warp and shoot in such a manner that a difference of texture shall occur in the web so as to mark out any pattern. This is effected in the single-hand loom by a multiplication of treadles connected with the lisses by which the different portions of warp are alternately raised. Forty treadles have been sometimes required to form an intricate pattern. Small figures produced in this manner are called *leys*. To execute more complicated patterns, *tires* or *draws* are used. Tires are cords hung over the top of the loom, and pulled by the hand as the figure may require; they work like the treadles, by raising the lisses, through the eyes of which are passed the threads to form the pattern. Small patterns are still largely made in the single-hand looms by means of treadles and tires. The French single-hand loom of this description is called *hautelisse*. This was the name of the loom used in weaving the best tapestry, in which the warp was stretched perpendicularly, and hence it came to be applied to other looms for weaving figures. The production of a large pattern in this manner is difficult and tedious. Many skilful contrivances have been devised by weavers and others for facilitating the operation, and among others the *draw-boy*; but they were all superseded by the introduction of the Jacquard machine. [JACQUARD APPARATUS.]

The work is ordinarily given out in *sets of grosses*, consisting of two warps for each shuttle, each warp containing two pieces of 36 yards. The ribbons are cut out in pieces of 36 yards if they are of satin, and in half-pieces of 18 yards if they are sarsenets or gauzes above the narrower widths. A set of pieces cut out of a loom is called a *length* and a set of half-pieces a *half-length*. The putting in of a fresh set of warps is a tedious operation, which requires from two or three to fourteen days, and proportionally lessens the earnings of the weaver. A simple change of pattern, however, is often effected with very little loss of time. Whenever it is practicable, the ends of the new warp are fastened to those of the old before it is taken out of the loom, whereby the labour of passing them separately through the eyes or mails of the lisses is saved: this is called *twisting in*.

Ribbons are made according to a fixed standard of widths designated by different numbers of pence, which once no doubt denoted the price of the article, but at present have reference only to its breadth. The French distinguish their widths by simple numbers. Thus the English ribbons from a quarter of an inch to about 4½ inches wide are called from *penny* width to *forty-penny* width; while the French have figures from No. 1 to No. 60. All dressed ribbons, as satins, gauzes, &c., are made in the loom one-twelfth of an inch wider than sarsenets, in order to allow for the diminution of breadth which results from the lengthwise stretching they receive in the operation of dressing. Fine gauzes require an allowance of two-twelfths. The French ribbons were made formerly in pieces of 12 ells; their length is now the same as that of the English. French fancy ribbons are generally made and sold in *garnitures*; that is, a broad and narrow piece taken together of the same pattern.

Sarsenet and *lutestring* ribbons are made by the simple and regular alternation of the warp and shoot, as in plain cloth, called technically *ground*. Lutestrings are sarsenets above the width of 12*d*., and in general of stouter make. By *grogram* (French *gros-grains*) is meant a variation in the texture, caused by the warp-threads passing over two of the shoots at once, taking up one only: this often finishes the edge of a ribbon. In *satin* ribbons, the glossy appearance is given by the threads of the warp being laid chiefly on the surface, each thread of the warp being crossed by the shoot only once in five times, as in 5-lisse satin, or once in eight times, as in 8-lisse or the superior satins. French satins were formerly made from 6-lisse to 10-lisse. Satins are woven with the face downwards. The French satins are lighter in make than the English, but have a peculiar richness and lustre, owing to their superior silk. French ribbons in general have less weight of silk than the English. The transparency of *gauze* ribbons is produced by the kind of silk of which it is made—the fine hard-twisted marabout, which leaves the interstices clear. One warp thread only passes between each dent of the sleigh, and these are closer together in general than lutestrings and satins. In fine gauzes, there are 80 or more dents, and from 90 to 120 shoots to the inch. The plain gauze ribbons made at Coventry called China gauzes are chiefly those used for mourning—white, black, and lavender, with satin or ground stripes. *Florets*, *taffeties*, *loves*, and *petershams*, are other kinds of gauze ribbons. These ribbons all belong to the plain trade. The fancy trade comprises the manufacture of the same fabrics figured, under the heads of figured sarsenets, satins, gauzes, &c. The figures are frequently produced in a different colour from the ground by the mixture of colours in the warp, the colours being warped separately. In the intervals of the figures the coloured threads are carried along the under side of the ribbon, it is said to have a *double* or *treble figure*, according to the number of colours passing through each dent. In some ribbons—gauzes in particular—these threads are cut away by the scissors after the ribbon is made. This is called *clipping*. A change of colour in the shoot is effected by the use of different shuttles; in brocades the figure is made by small additional shuttles, thrown in partially across the ribbon as the pattern may require, the connecting threads of shoot being clipped off. By *damask* is meant the laying of the warp over the shoot to form the figure, in the manner of satin. The patterns are sometimes geometrical, but more frequently combinations of leaves, sprigs, or flowers. In the superior French ribbons, groups and wreaths of flowers are executed with the richness and variety of hand-embroidery. The French are continually introducing novelties in colouring and in texture. Some fancy ribbons are of a plain texture, but varied in colouring; they are shot or woven in shades, stripes, bars, or cheques, called in the trade *plaids;* these last, which require the shuttle to be changed very frequently, are still made in the single-hand loom. In *shot* ribbons the warp and the shoot are of different colours. A *pearl-edge* is frequently given to all kinds of ribbon except the narrower widths of sarsenet. This is formed by the shoot passing over horse-hairs placed outside the warp parallel with it, and raised in like manner by the lisses; as the hairs are drawn out, the silk is left in loops at the edge. Many varieties of ornamental edges, as scollops, fringes, &c., are produced by *drawing in*. The shoot in this case stops short of the edge of the ribbon, catching in an additional thread of silk, sometimes of a different colour, which it draws in in its place, and which is delivered from a bobbin at the back of the loom, and is in a manner darned into the ground of the ribbon. *Clouding* is a peculiar management in the dyeing, by which a change of hue is produced in the same thread of silk. The silk, already warped, is tied up and wound closely round with packthread at regular intervals of more or less than an inch, so that the intermediate spaces only are penetrated by the dye. In one species of fancy ribbon, called *Chiné*, the figures are printed or painted on the warp after it is prepared for the loom, and afterwards woven in by the shuttle; others are embossed. Ribbons are *watered* by passing two pieces together between two cylinders, one of which has a heater within it; the irregular pressure of the inequalities of the two surfaces of silk against each other produces a wavy appearance. To smooth and stiffen satin ribbons, they are *calendered*, or pressed between heated steel cylinders, and afterwards dressed, or passed over a small cylinder covered with flannel, which is moistened with a size made from buffalo hides, and then over a large one of heated steel. Gauzes also are dressed, and sometimes even lute-strings. The French goods are in general better dressed than the English. The *blocking* of the finished ribbons, or the winding them on cylindrical pieces of wood, is generally done at the warehouse of the manufacturer. *Galloons* and *doubles* are strong thick ribbons, principally black, used for bindings, shoe-strings, &c. The narrow widths are called galloons; the broader, doubles. Italian silk is used in making the best qualities only, Bengal for the commoner. *Ferrets* are coarse narrow ribbons shot with cotton, used for similar purposes. *Ribbon velvets* are manufactured in Spitalfields, and at St. Etienne: they are also made at Crefeld, in Rhenish Prussia, which has long been a principal seat of the velvet manufacture. In *gold* and *silver* ribbons, a silk thread of similar colour is wound round by a flattened wire of the metal, and afterwards woven. Lyon was at one time particularly celebrated for its fabrics of this kind.

In the ribbon manufacture the labour is nearly the same for the richer as for the inferior goods, the difference consisting principally in the silk of which they are made. Cheap ribbons are generally made by reducing the warp silk, which is the most expensive, and making up the bulk of the ribbon with a larger proportion of the cheaper shoot.

There are certain small wares which may be briefly noticed here, midway in character between *cords* and *ribbons*, and yet more complex than either. These are *gimps, twists, fringes, chenilles*, &c.; in which the results are produced in some few cases by a kind of weaving, but much more frequently by a twisting or looping process. Complicated machines are needed for the production of such goods; and many patents have been obtained for inventions tending to this end. In one contrivance, a looping-machine invented by Messrs. Keely and Wilkins, while one arrangement is suitable for the making of stockings and gloves, another is intended for the making of braids, several at a time, and of one, or of several patterns. A third modification of the same apparatus enables the manufacturers to *plate* or cover any cheap kind of thread with thread of a better sort. A machine invented by Messrs. Hughes and Denham is intended equally for the making of fancy ribbon, fringe, chenille, trimmings, and gimps. There is no actual weaving process adopted, but the appearance of the goods is somewhat as if woven. The apparatus is very complex, consisting of many parts spinning round each other. A ground thread is sometimes formed of wire covered with cloth, or of narrow strips of stiff paper; and the machine will cover these with silken thread. Ornamental trimmings may be made by feeding the machine with strips of tarlatan, muslin, silk, or quilling as a ground, and then winding silk thread round them. Wire groundwork may be used for making chenille; and minor adjustments will furnish the means for making an almost endless variety of fancy goods.

RICE; RICE-MILL. In the article ORYZA, in NAT. HIST. DIV., an account is given of the botanical character, and under ORYZA in the present division the mode of cultivation is described. In order to remove the husk, which adheres very closely, without breaking the grain itself, several ingenious machines have been recently introduced, of some of which it is proposed to give a brief notice.

The common mode of performing this operation in India and China, is by beating the grain in a kind of rude mortar of stone or earthenware, with a conical stone attached to a lever worked by the hand or foot. Sometimes several such levers are moved by arms projecting from the axis of a water-wheel. This process being uncertain and tedious, the preference has been given of late to a kind of mill, in which the stones are placed at such a distance asunder as to detach the shell without crushing the grain; the stones being enclosed in a case which prevents the dispersion of the rice by the rapid rotation of the machine. The rice is thrown out of the case by an opening in its side, and conducted over a sieve that separates the dust; after which it is made to fall in a gentle stream exposed to a current of air, produced by revolving fanners, and thereby separated from the husk. Such a sifting and winnowing apparatus is attached to each pair of stones, and one pair of stones will husk from eight to ten bushels an hour. After the removal of the husk, the grain is exposed to the action of a whitening machine, which removes the inner cuticle, or red skin, remaining on the surface of the grain. This process is aided by the heat generated by the rapid motion of the grains, causing them to swell and split the red skin, which flies off in dust through perforations in the revolving case. With such accuracy are these processes performed, that it is said not more than five per cent. of the grain is broken in the operation.

The method of cleansing rice just described has been practised in Ceylon with British machinery; but other plans have been followed in this country, where, owing to the difference between the duties on cleaned rice and *paddy*, or grain in the rough state, and the better preservation of the flavour of the rice when brought over in the husk, several large rice-cleaning establishments have been gradually brought into operation. The process of Messrs. Lucas and Ewbank consists in breaking the husk by millstones, and removing the red cuticle by beating or triturating in mortars; the latter operation being aided by mixing a quantity of the husks, well dried, with the grain, which obviates an inconvenience occasioned by the glutinous character of the red coating. The refuse matter and the broken grains are then separated by a peculiar kind of screen; and the rice is finally cleaned and polished by a machine with two concentric cylinders, the outer one remaining stationary, while the inner one, which is covered with sheepskin with the wool on, is made to revolve with great velocity. The rice, being placed between the two cylinders, is thoroughly whitened by the friction of the wool.

In the apparatus patented by Mr. Shiel, the first operation is performed between one millstone and a piece of wood of precisely similar shape; and the subsequent removal of the dark pellicle is effected by rubbing between flat wooden surfaces covered with sheepskin. Mr. Ewbank places the wool outwards, Mr. Shiel has it next the wood; its elasticity producing an effect very nearly resembling the rubbing of the grain between the palms of the hands.

Another ingenious contrivance, first used in the United States, consists of a long hollow cylinder of wood, with several bars projecting from its inner surface, and enclosing an axis on which are several other bars capable of revolving between those attached to the cylinder. By suitable toothed wheels the cylinder is made to revolve slowly in one direction, while the axis is turned with great rapidity in the contrary direction. The whole being placed in an inclined position, the paddy is allowed to enter the upper end of the cylinder by a hopper; and the mutual attrition of the grains, as they pass between the revolving bars, causes the separation of the husks, which are removed by a current of air as the grain falls into a bin under the lower extremity of the cylinder. The rice passes out of the cylinder by apertures capable of being enlarged or reduced at pleasure by means of sliding doors; and the action of the machine may be further regulated by varying the inclination of the cylinder, which may be placed vertically or horizontally, though an angle of about 45° is preferred.

Rice is, as is well known, chiefly used as food, but it is also employed to some extent in the arts. A cement is made from it. *Rice-paper* is a name commonly, but erroneously, applied to a delicate vegetable film brought from China in small square pieces, tinged with various colours, and used as a substitute for drawing paper in the representation of richly coloured insects or flowers, and also in the manufacture of artificial flowers and other fancy articles. This substance, a membrane of the bread-fruit tree, though much resembling an artificial production, is evidently of natural growth; for its vegetable organisation is easily seen by the aid of a microscope. Sir D. Brewster, in the 'Edinburgh Journal of Science,' vol. ii., has shown that the rice-paper consists of long hexagonal cells, whose length is parallel to the surface of the film; that these cells are *filled with air* when the film is in its usual state; and that from this circumstance it derives that peculiar softness which renders it so well adapted for the purpose to which it is applied.

The quantity of rice imported into this country varies very much, owing to the fluctuations of the crops. During the last fifteen years it has varied from 269,314 cwts. (in 1845) to 1,744,913 cwts. (in 1858). This was for *home consumption*; there has generally been a still larger quantity imported simply for re-exportation, insomuch that the total import for 1858 was more than 3,600,000 cwts. This is rice, "not in the husk," to use a Customs' phrase. Rice in the husk, or paddy, is entered separately. Before the year 1842, cleaned rice paid a duty of 1*s.* per cwt. if from our own possessions, and 15*s.* if foreign. Since that year the duty on colonial and Indian rice has been lowered from 1*s.* to 4½*d.*; and on foreign from 15*s.* to 4½*d.* The lowering of the duty has been followed by a rapid increase of consumption. Paddy pays a lower duty than cleaned rice.

RICINELAIDIC ACID ($C_{36}H_{34}O_6$). *Palmic Acid.* When ricinelaidin is saponified with boiling potash lye, the soap subsequently precipitated with salt, and then decomposed by hydrochloric acid, ricinelaidic acid separates as an oily body, that solidifies on cooling to a crystalline mass, which may be purified by repeated crystallisation from alcohol. It presents the appearance of silky needles, which redden litmus and are soluble in all proportions in alcohol and ether.

RICINELAIDIN ($C_{75}H_{72}O_{18}$), *Palmin.* A product of the action of hyponitric acid upon castor oil. It is a wax-like body with an odour of hydride of œnanthyl. It is very soluble in alcohol and ether.

RICINOLAMIDE ($C_{36}H_{35}NO_4$). A colourless, crystalline, fusible substance, produced by acting upon castor oil with ammonia. Mineral acids decompose it in the cold, setting ricinolic acid at liberty.

RICINOLIC ACID ($C_{36}H_{34}O_6$), *Elaiodic Acid.* The liquid fatty acid obtained by saponifying castor oil. It is soluble in all proportions in alcohol and ether, reacts acid, and decomposes carbonates with effervescence.

RICINUS COMMU'NIS, the castor-oil plant, known from very ancient times both to the Egyptians and also to the Greeks. According to Herodotus (ii. 94), the Egyptians called the oil of the *sillicyprion* (*σιλλικύπριον*) by the name *Kiki* (*κίκι*). The Greeks also called it *Croton* (*κρότων*), a name bestowed by modern botanists on a closely allied genus of euphorbiaceous plants, one species of which yields the purgative oil designated Croton oil, or Oleum Tiglii. The native country of the Ricinus communis is unknown, though it is conjectured to be originally from Barbary. Like all plants which have been long in cultivation, numerous varieties of it are met with, differing not only in colour and the peculiar pruinose condition of the stem, but in stature and duration. In warm countries it is ligneous and perennial; in cold, annual and herbaceous. The entire plant is possessed of active properties, but the oil extracted from the seeds is only employed in Europe; the ancients administered the seeds entire, but their variable action, occasionally even producing fatal effects, led to their disuse, and the oil is of comparatively recent introduction. The seeds, of which three are found in each capsule, are about the size of a small bean, obtuse at both ends, surface smooth, shining, and beautifully marbled. The skin consists of three tunics—1st, an outer brittle pellicle; 2nd, a hard testa consisting of two dissimilar layers, the external thick, dark brown, formed of transverse radiating cells; the internal thinner, paler, and formed of vertical cells; 3rd, a membrane investing the nucleus or kernel. "The nucleus consists of oily albumen, and an embryo, the cotyledons of which are membranous or foliaceous." The outer shell is devoid of taste; in the inner coat the acrimony or active principle resides, according to Dierbach; while others assert the embryo to be the seat of the purgative principle; and even Humboldt and Bancroft state that if this part be excised, the seeds may be eaten with impunity, or the oil thereafter expressed is as mild as olive-oil. Various procedures have been adopted to extract the oil, and these have much influence on its qualities in respect of colour, acridity, and freedom from rancidity; there are also effects which result from the greater or less maturity of the seeds, the peculiar variety of the plant from which they have been obtained, and the occasionally accidental, but more frequently intentional admixture of other seeds, before the different processes of extraction have been begun. Both in India and America, whence the first supplies were brought, much heat was employed, and during the application of this agent a volatile principle was either liberated, or more probably formed, which was so irritating as to require the workmen to protect their faces by masks. Even in the present day some heat is used to obtain what is termed the *cold drawn* castor-oil, but it is quite unnecessary, and should always be avoided.

According to Sir Whitelaw Ainslie ('Materia Indica,' vol. i. p. 256), the following is the plan pursued in the East Indies:—"Take five seers of the small castor-oil nuts, and soak them for one night in cold water; next morning strain this water off and throw it away, and put the nuts into a second quantity of fresh water, and boil them in it for two hours; after which strain the water off and throw it away, as in the first instance; the nuts then are to be dried in the sun on a mat for three days; at the end of which time they are to be well bruised in a mortar; add to the nuts thus bruised ten measures of water, and set the whole on the fire to boil, taking care to keep continually stirring the contents of the pot until all the oil appears at the top, when it is to be carefully strained off and bottled for use. The quantity of nuts mentioned in this formula ought to yield about one quart bottle of oil." The processes used in the United States and the West Indies are both objectionable, from employing not only heat but water, which last promotes the rancidity of the oil. The acrid property and the rancidity are owing to different causes, the former being always in proportion to the freshness of the oil, the latter to the imperfection of the means used in extracting it, or to its age. The plan adopted in France is the best; it is as follows:—The fresh seeds are bruised, and then put into a cold press (some persons improperly heat the plates of the press). The oil expressed is allowed to stand some time to permit the albumen, mucilage, and other matters to subside, or it is filtered to separate them more rapidly. ('Journal de Pharmacie,' tom. v. pp. 207, 508.) The produce is equal to about a third of the seeds employed, and the oil possesses all its natural qualities. The American process yields only 25 per cent. of oil. In the French West Indian Islands, a peculiar variety of Ricinus, called *R. ruber*, more active, is used, which yields an oil called *carapat*, or *karahat*, but this is violent and unpleasant, and must not be confounded with or substituted for the fine oil procured in France. Both the French and Italian oils are much weaker than oil procured from tropical countries. Another mode of obtaining the oil is to macerate the bruised seeds in cold alcohol, by which six ounces of oil are procured from every pound of seeds. ('Journal de Pharmacie,' viii. 475.) The expense of this process is the objection to its general employment.

Oil of good quality is a thickish fluid, of a very pale yellow colour (the best now almost limpid), with a slightly nauseous odour, and an oily taste, mild at first, but causing a feeling in the back of the throat which is more or less intense in proportion to the freshness of the specimen. Old or badly prepared oil is rancid and disagreeable. The specific gravity is, at 55° Fahr., 0·969, according to Saussure, but according to Geiger it is only 0·954.

It can be solidified only by a very low temperature. It is distinguished among fixed oils by its complete or nearly complete solubility in pure sulphuric æther and in alcohol, thereby approaching the essential oils in its habitudes, and its easy combination with alkaline leys, and consequently its ready saponification, two properties of much importance, the one furnishing a convenient test of its purity, the other facilitating its administration in a form less repulsive than its ordinary state. Its purity may be tested by mixing it with an equal quantity of absolute alcohol, in which it should be entirely dissolved; the adulterating oil, if there be any, will remain undissolved. Its ultimate composition seems to be—

	Saussure.	Ure.
Carbon	74·178	74·00
Hydrogen	11·034	10·29
Oxygen	14·788	15·71
	100·000	100·000

It thus appears to be one of the most highly oxygenated oils or fats, notwithstanding which, on exposure to the air, it very readily absorbs more oxygen, and quickly becomes rancid; it is however slow of drying. It is stated to consist of several proximate principles, but whether these are educts or products is uncertain. Bussy and Lecanu, who have paid great attention to the subject ('Journal de Pharmacie,' xiii. 57) incline to the latter opinion, which is the most probable. "This oil," they state, "cannot be regarded as a simple immediate principle, but as a *compound organic product* resulting from the mixture of at least two different substances." The other view is that it is a compound of *three fatty acids saturated by glycerin*, for in the process of saponification 100 parts of castor-oil yielded—

1. Fatty acids (viz., ricinic, elaïodic, and margaritic acids)	94
2. Glycerin	8
	102

Saalmuler admits only two fat acids and a little acrid resin. These acids are formed during saponification from Ricin-oleine and Margaritine.

The only analysis of the seeds is that of Geiger ('Handbuch der Pharmacie,' ii. p. 1671).

For further details respecting the chemistry of castor-oil, see Pereira's 'Mat. Med.,' ii. p. 1287, edit. of 1850.

Castor-oil is a mild aperient or laxative when pure, operating without griping or other inconvenience, and commonly very soon after its administration. It is the most proper laxative for infants, and in many inflammatory states of the abdomen or of the kidneys, bladder, &c. It is also one of the best purgatives in rheumatism, especially in lumbago, and one of the best means of relieving habitual constipation, as, unlike other purgatives, the dose may be successively reduced without its power being impaired. It is also a most eligible medicine in piles or other affections of the rectum. Alone or with turpentine it is a very efficacious means of expelling worms. The chief obstacle to its extensive use is the repulsive taste which it often possesses. Many expedients have been adopted to remove or lessen this; but no artifice can make bad or old oil good or palatable. Rancid oil may be purified by calcined magnesia; but the careful exclusion of the air, which prevents the rancidity occurring, is preferable to any process for removing it when it has affected the oil. Mixing the oil, immediately before swallowing it, with hot milk, coffee, or broth, is sometimes a successful means of escaping the unpleasantness. Besides this the heat not only renders the oil thinner, but quickens its action, so that a less quantity is needed. Thus administered, about one-half the quantity will suffice which is needed when given in any cold vehicle. Brandy and gin are improper in many cases, owing to their heating properties. Syrup of orange and lemon are beneficial adjuncts, especially if a portion of the orange-peel be masticated immediately after swallowing the mixture. An emulsion with yolk of egg is sometimes acceptable, if made immediately before it is administered. By far the best plan however is to take advantage of the tendency to combine with alkalies, and so form a soapy emulsion, which does not destroy the purgative power, while it completely alters the appearance, and prevents any one recognising the oily object of his aversion. To effect this however requires care and skill, especially as a variable quantity of alkaline ley is needed, according to the age of the oil, very old oil requiring more ley than fresh oil. In general from fifteen to twenty drops of pure liquor potassæ will saponify half an ounce of oil, to which one ounce of distilled water, and one drachm of spirit of pimento or of nutmeg are to be added.

Castor-oil is extensively used in the East, France, Italy, and elsewhere, for burning, and lately to make soap.

RICKETS, or Rachitis (from ῥάχις, the spine), is a disease in which the bones being of unnatural softness, some of them bend under the weight of the superincumbent parts of the body. Bones affected with rickets present such a softness of texture that they may be cut with a knife; their walls are remarkably thin, and their interior, instead of being filled with marrow deposited in their bony cells, is occupied by a semi-fluid jelly-like substance of a reddish colour, which fills a number of rounded cavities of irregular size. The quantity of earthy matter in such bones is reduced to considerably less than its natural proportion, and they lose much of their normal weight. All the bones may be thus affected, but it is only those which have to bear the weight of the body that give evidence of it by bending; the arms, for example, never change their form, but the thighs and legs become arched forwards under the weight of the trunk; the spine assumes a variety of curves from the pressure of the head; the breast-bone becomes prominent, and the ribs flattened; the haunch-bones grow outwards, and the pelvis is sometimes seriously deformed by an approximation of its anterior and posterior boundaries.

Rickets, as far as the softness of the bones is concerned, cannot be regarded as a dangerous disease; for this condition is generally recovered from, though not without deformity of the trunk and lower limbs. But the disease of the bones is commonly only a part of a general state of disease affecting many other organs of the body. The muscles are always pale and weak, and there are all the signs of general debility; and besides these, the brain and the organs contained in the chest and abdomen are peculiarly apt to suffer, and become the seat of fatal diseases, such as hydrocephalus, phthisis, obstruction of the mesenteric glands, &c.

The general symptoms present in cases of rickets are so much like scrofula, that many writers treat rickets but as one of the many forms in which scrofula presents itself. [Scrofula.] At any rate, in the treatment of rickets the same general plan is found to be equally efficacious. The causes of rickets are to be sought in an improper diet, and exposure to those conditions of life which prevent a due oxidation of the blood, and an imperfect assimilation of the food. It is more frequent in children living in large towns or overcrowded villages, than amongst those who obtain healthy food and pure air. One of the most important elements of treatment is the removal of the patient from any overcrowded district in which it has been living into the country, where it can have pure air, and if possible sea air. In young children, fresh cow's milk, with baked wheaten flour, and meat teas, should be administered. Cod-liver oil should be given as medicine, and cream may be added to the cow's milk, and butter may be freely taken with the food. The deficiency of phosphate of lime may be repaired by the administration of jellies made from ivory or bone dust, which may be made palatable with spices and sugar.

When rickets affects only or chiefly the bones, an attention to the means just mentioned will, with advancing age, usually lead to a termination of the disease. The bones will gradually become hard by the addition of their natural quantity of earthy matter. They retain indeed the curves which they acquired in their condition of softness, but the want of strength which might result from this change of form is compensated by the remarkable thickness and strength which they acquire in the concavities of the curves, upon which the chief stress from the weight of the body falls.

Young persons are exclusively subject to rickets. It occurs at the age of two or three years, and from that time to puberty, and as the curvatures begin to form as soon as the weight of the body is thrown on the limbs by assuming the erect posture, it is commonly proposed to support the upper part of the body and the limbs by *irons*. Such measures however are, in a large majority of cases, full of mischief; if they can ever accomplish their intention of supporting the head and trunk, it can only be by preventing entirely that active use of the limbs which is essential to the attainment of the proper hardness of the bones. It is constantly observed that the strength and density of bones are in direct proportion to the habitual exertion of the muscles attached to them; and as the latter are made inactive by irons, the application of any such modes of restraint cannot but be injurious to those affected with rickets.

When children first begin to walk, their legs not unfrequently become a little bent. This is especially the case with those that are large, and have heavy bodies to bear; but it is not to be regarded as a sign of rickets, and when the muscles of the limbs become stronger, and the bones in their natural process of development grow harder, the curvatures will gradually disappear. The distinction between this kind of bending of the legs and that dependent on rickets may be made by the condition of the general health in each; in the former it is unaffected, or may even be more than usually good, in the latter it is always weak and disordered.

RICOCHET, a word expressing the act of rebounding, is applied to the mode of firing ordnance in which (the axis of the piece being parallel, or inclined at a small angle to the horizon) the shot or shell, having described a curve in the air, descends to the ground, and, after striking or grazing it, rises upwards; when, by the force of the impulsion, and the power of gravity, it describes a second curve of small elevation; the shot, then descending as before, again grazes the ground, from whence it experiences a second reflection. This effect frequently takes place several times before the force of impulse is destroyed.

Ricochet firing is most generally employed in the attack of fortresses in order to enfilade or rake the faces of works, whose fire might be directed upon the ground on which the approaches are to be made: for that purpose a battery of the besiegers is placed with its front perpendicular to the prolonged direction of each rampart or parapet, and three or more guns are laid either horizontally or with slight elevations or depressions, according to the position of the battery, so that their shot may pass a little above the crest of the parapet which covers the line to be enfiladed. The same mode of firing is also occasionally employed by the besieged against the batteries of the enemy. In either case the intention is to dismount the artillery by causing the shot or shells to strike it obliquely behind the parapet or epaulement, or to destroy the traverses which cover it. It is also used to compel the troops to abandon the parapets, or to destroy the palisades of the covered-way or ditches, so as to facilitate the entrance into a work when an assault is to be made by main force.

The practice of firing à-ricochet was first tried by Vauban at the sieges of Philipsburg and Mannheim, in the war of 1688; and in a letter which that engineer wrote to Louvois, he states that at the former place it had succeeded so far as to dismount six or seven pieces of cannon, and oblige the defenders to abandon a long branch of a hornwork and a face of one of the bastions in front of the ground on which the chief attack took place. The success of ricochet firing appears to have been still greater at the siege of Ath, which was conducted by Vauban during the same war.

It is a remarkable circumstance that, soon after the invention of this method of firing, the changes which were made in the trace or plan of fortifications, though attended with many and great advantages, were such as to render the works more liable than those of former times to the destructive action of the ricochet. The great saliency then given to the ravelins, and the consequent acuteness of the salient angles, allow the prolongation of the faces to be easily observed by the besiegers while at a distance from the work; and thus the guns in the ricochetting batteries are enabled to enfilade the faces in their whole length with great accuracy. The faces of the bastions were also lengthened about the same time; and in fortifications constructed on the inferior polygons, or those of few sides, there is a like facility of dismounting the artillery on those faces. The latter evil ceases to exist when the works are formed on the superior polygons, because the prolongations of the faces of the bastions may then fall upon the intermediate ravelins, and thus be invisible to the enemy; but, for the damage to which the long faces of the ravelins are exposed, no other remedy can be found than in the construction of traverses or blindages on the terrepleins, or in covering the general direction of the faces by an advanced portion of the latter, about twenty yards long, on each side of the salient angle.

The French engineers divide ricochet firing into two kinds, of which one is designated *ricochet mou*, and the other *rickochet tendu* (short and long-ricochet); the former comprehending all elevations of the piece, from the greatest which the charge and the gun-carriage will permit, to that which is but little above the horizon; and the latter term being applied to all other cases, down to that in which, from the height of the battery, the gun is depressed below the horizontal plane. When the crest of the parapet which covers the rampart or the ground to be ricochetted is above the level of the battery, the coincidence of that crest with the vertex of the trajectory forms the inferior limit to the elevation of the piece; for if the shot were to pass closely over that crest with a lower elevation, it would at that place be in the ascending branch of the curve, and then the ground behind the covering parapet would not, to a considerable distance from thence, be struck. In proportion as the elevation of the piece is increased above the same limit, the vertex of the trajectory is nearer to the battery, and thus the shot is in the descending branch when it passes over the crest of the work.

When the parapet over which the shot is to pass has little elevation above the battery, it requires considerable charges to allow the vertex of the trajectory to coincide with the crest; but the charges diminish rapidly as the height of the parapet increases, or as the distance of the battery from thence diminishes: the effect of this is to produce the kind of ricochet first mentioned above, for the angle made by the descending branch with the horizontal ground being greater, the rebounds of the shot are more numerous within a given extent of ground, and between the successive grazes the curves are higher and shorter. In this case, and when the descending branch passes through the crest, the shot falls almost immediately behind the parapet, and no part of the ground to be ricochetted is free from its action: this is not always certain, when by great charges and low elevations the second kind of ricochet is used, since it may happen that the shot will pass above the objects which it should strike within the limits of the ground. In the modern system of fortification the greatest length of the faces of works which are liable to the ricochet is about 100 yards; therefore when there are no traverses on the terreplein, and it is merely required to strike an object somewhere between the crest of the covering parapet (supposed to be about 8 feet high) and the further extremity of any such face, the descending branch of the trajectory will make with the horizon an angle of about one degree, and the charge and elevation of the gun should be determined so that this condition may be fulfilled. From shot so fired a traverse near the covering parapet would entirely protect the ground, since the projectile would lodge in it, and do no harm to the defenders; and in order that the fire of shot may do execution, whether made in that manner or with an increased elevation of the piece so as to produce ricochets, it is necessary previously to destroy the traverse by shells fired as above described. For such a purpose General Millar's 8-inch howitzers will probably be found to be the most serviceable; and if the large shot subsequently fired à-ricochet to dismount the artillery should not succeed in clearing an enemy's work of the troops who defend the parapet, spherical case shot fired from 24-pounder guns might be advantageously employed. One gun in a ricochet battery should be exactly in the prolongation of the crest of the parapet on the face to be enfiladed, in order that its shot may graze, with the long ricochet, the interior slope of such parapet.

Experiments in ricochet firing were carried on at Woolwich, in the months of June and October, 1821, when a work 100 yards long, and resembling the face of a bastion or ravelin, was enfiladed in that manner with iron and brass ordnance of different natures; the covering face was eight feet high, and its crest was nearly on a level with the axes of the guns in the battery. The results were, that with a range equal to 400 yards, and a charge of powder equal to $\frac{1}{16}$ of the weight of the shot, about two-thirds of the number of rounds took effect; at 600 yards, with charges varying from [illegible] to [illegible] of the weight, from one-third to one-half took effect; and at 800 yards, with charges from [illegible] to [illegible], between one-third and two-thirds took effect. It was concluded therefore that ricochet batteries ought, if possible, to be at a distance varying from 500 to 600 yards from the nearest part of the line of rampart to be enfiladed; for beyond the latter distance the effect of the fire is uncertain. The long ricochet, with high charges and small elevations or depressions of the guns, may, however, be advantageously employed in firing from the ramparts of a fortress on the ground in front, or against extensive lines of works when the battery is at a much greater distance.

It appears from the experiments above-mentioned that the best elevations of ordnance for enfilading a work à-ricochet with shot or shells is that in which the axis of the piece is directed at an angle varying from 6° to 9° above a line drawn from the chamber of the gun or howitzer to the crest of the parapet over which the projectile is to pass. It is stated that of 170 shells filled with powder which were fired, 58 took effect, but only 33 burst in the work. Before the traverses were constructed several guns on the work were struck and rendered useless; but afterwards, though the traverses were much injured, none of the guns protected by them were disabled.

When employed against troops in the field, ricochet firing is found to be of essential service; for the shot making on the ground eight or ten grazes, it cannot fail at some of these to take effect. In 1757, the King of Prussia had several six-inch mortars mounted on travelling carriages; and from these he caused shells to be thrown à-ricochet, in an oblique direction, against the enemy's line, which it immediately put in great disorder.

Ricochet firing, when first employed in sieges, from the defenders not being prepared with means to diminish its destructive effects, produced immediately a strong impression of its power; and the opinion of its superiority to the direct mode of firing has continued to prevail from the time of Vauban to the present day, though the service of artillery is now so precise, that when the guns in an enemy's work can be seen, they can be as readily dismounted by the latter mode as by the ricochet. It ought also to be remembered that before the latter can be usefully employed, the parapets, traverses, or blindages which cover the artillery of a fortress must be ruined by other means; and it may reasonably be concluded that the rapid reduction, or the most protracted defence of a place, will always be owing to a judicious combination of the different modes in which, according to the circumstances, artillery can be used during the siege. [SIEGE.]

Though it has been stated that with Mr. Whitworth's rifle gun some very good ricochet practice has been made, it is very doubtful whether rifle cannon can be employed for this purpose, as from the rotation of the shot it is deflected immensely on striking the ground. In fact, this is one of the disadvantages of rifle guns.

RIFLE, or RIFLED, a term applied to muskets or pieces of ordnance when their bores are furrowed with spiral grooves. It is probably derived from an Anglo-Saxon word signifying to *rive* or *tear;* the grooves or channels being formed by a machine which scrapes away the substance of the barrel interiorly in parallel and spiral directions.

It is not precisely known at what time rifled barrels were first employed in warfare, but P. Daniel states ('Hist. de la Milice Française,' liv. vi.) that the carabiniers of the French cavalry were furnished with such arms; he also observes that they had been invented long before the time at which he wrote, and that he had seen them used before that class of troops was formed into a regiment. This circumstance took place in 1692, and we may therefore conclude that rifled arms were known on the continent about the middle of the 17th century. The historian describes the *carabines rayées*, as he calls them, as being grooved in a circular manner along the whole of the barrel; and he asserts that the range of the balls fired from them was very considerable. Rifled arms do not appear to have been introduced in the British service till the time of the American Revolutionary war.

It is sometimes asserted that grooved barrels were introduced by Gaspard Zollner of Vienna, in 1498, but these grooves were parallel to the axis of the piece, and were only intended to take off the foulness of the discharge and assist in loading. It may accidentally have been discovered that by making the grooves spiral, greater accuracy was obtained. It is also asserted that elongated projectiles were fired from rifles many years ago, as, for instance, it is stated that Hamilton of Bothwell-haugh shot the regent Murray with a cylindro-conical bullet. But it is difficult to determine this with any certainty. Under the head of GUNNERY the effect of the rotation of a projectile has been investigated, and it is there shown that, except when the axis of rotation is coincident with the line of flight, or speaking more correctly as the trajectory is a curve, except when the axis is tangential to the trajectory, the effect of rotation on a projectile passing through the air is to deflect it more or less from the direction in which it is projected. This effect is due to the fact of the surface of the projectile being more or less rough, and to the atmosphere being more condensed in front than behind it from its high velocity. But it is not the *direct* result, if we may so term it, of the greater friction in front than behind the centre of gravity, as is often erroneously stated, and this the experiments of Professor Magnus of Berlin have shown. Indeed, the direct effect of this friction would be to deflect the ball in exactly the opposite direction to what in practice is found to be the case. A ball, for instance, rotating on a vertical axis, when the anterior surface is moving from right to left, would, the air being more condensed before than behind, meet with a great resistance to rotation from the friction of the air in front, which would not be counter-balanced by an equal resistance in the opposite direction behind; but as the rotation in front is from right to left, this resistance would in effect tend to deflect the centre of gravity from left to right. Now in practice it is found that a rotation from right to left deflects the ball to the left, so that it is evident that some other force must be called into action which overcomes this direct effect of friction. Now one half of the ball, supposing it to be cut into two hemispheres by the plane of the trajectory, is rotating with, and the other half in a contrary direction to, its motion of translation, and the surface of the ball not being perfectly smooth, the air is assisted in rushing past the former hemisphere, while it is retarded in passing the latter, and becomes more condensed. The experiments of Professor Magnus, in which a current of air was thrown on a rotating cylinder, clearly showed by an arrangement of vanes, which it is unnecessary to explain here, that the rotating cylinder caused a current in the air in contact with it, in the direction of the rotation which, where it met the current thrown on it by the blowing fan, produced a greater pressure of the air on that portion of the cylinder: that is, where the latter current was moving in an opposite direction to the former. Returning again to the ball rotating from right to left, this will account for a greater pressure on the right side than on the left, tending to deflect the ball to the left, and this cause of deflection is found to overcome the tendency before spoken of to deflect it to the right. The *figs.* 1 and 2 on the accompanying diagram may make this clearer. The motion of rotation is in both cases indicated by the arrow on the circumference, the motion of translation by the arrow in the circle. *Fig.* 1 gives the resultant direction from friction only; *fig.* 2 shows the condensation of air from the two currents meeting. It is most probable that the velocity of rotation is not so rapidly destroyed as the velocity of translation, which will account for the lateral deviation of a rotating projectile being found in practice to increase in a much greater ratio than the distance:—the trajectory being in fact a curve of double curvature. This was very well shown by Robins, to whom the first investigation, and indeed the principal portion of our present knowledge of this subject is due, in his experiment before the Royal Society in 1746, in the gardens of the Charter House (see page 165, Boxer's 'Treatise on Artillery'), where he fired a bullet from a bent gun-barrel through two paper screens, and on to a wall. The bullet followed the direction of the bent portion of the barrel in passing through the first screen and partially through the second, but the place where it struck the wall was on the other side of the line of direction of the straight portion of the barrel. The end of the barrel being bent to the left, the bullet in rolling against it in its passage out had received a rotatory movement, its anterior hemisphere moving from left to right, which for the reasons before stated caused it to deflect to the right, and the velocity of translation diminishing more rapidly than the velocity of rotation, this deflection was in a curve. This curve being combined with the curve caused by the action of gravity gives a curve of double curvature.

Fig. 1.

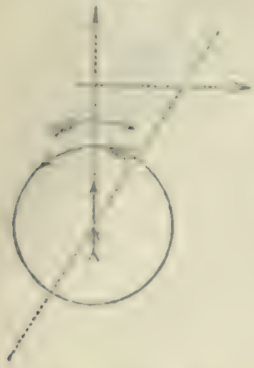

Fig. 2.

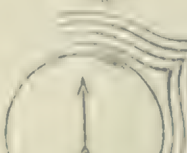


Let us now apply these considerations to the action of an ordinary smooth bore gun, whether musket or piece of ordnance.

In order that the shot may be forced down the bore of the gun it must be slightly smaller than the bore, the difference in diameter of the two being called windage. Windage, besides allowing a great escape and waste of gas, causes deflection in two ways, first the ball resting on the bottom of the bore of the gun is forced down by the gas rushing over it at the same time that it is forced along, and bounding up again from its elasticity it is carried along the bore, rebounding from side to side, and eventually leaves it, not in the direction of the axis, but in some other direction depending on its last impact. Secondly, from this last impact it will carry away a certain rotatory movement, which for the reasons before given will cause it to deflect.

The eccentricity of the projectile is another cause of deflection in smooth-bored guns. For the reasons given in the article GUNNERY, this eccentricity will in the bore of the gun cause rotation, and, as there stated, the effects of this rotation will be the same in nature as those due to the roughness of surface before considered, while they will be greatly augmented. Roughness of surface and imperfection of form are the last causes of deflection, and they are the means by which rotation causes deflection.

Windage may be lessened by increasing the size of the shot and various other means, but practically it cannot be destroyed, except in breech-loading guns.

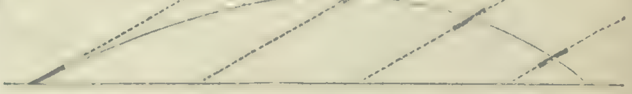
Eccentricity, arising from the material of the projectile not being homogeneous, is in musket bullets wholly overcome by making the bullets by compression, instead of casting them, as in cooling a void is often left in the interior; and may to a great extent be avoided by care in the projectiles used in larger ordnance.

Bullets can never be made perfectly smooth. Rotation can never be avoided in smooth-bored guns. It can to a certain extent be taken under control by making the shot purposely eccentric [GUNNERY], but this is a very uncertain process. We come then to the rifle, in which we have the power of impressing a certain fixed rotation on the bullet; a rotation always bearing in velocity a fixed relation to the initial velocity of the bullet. And in direction, a rotation which being round an axis that during the first portion of the trajectory, at all events, is tangential to it, causes the resistance of the air to be equally distributed round the pole of rotation, and brings any imperfections of surface rapidly round from one side to the other of the axis, and corrects any deflection arising from them at each half revolution of the bullet. Thus we obtain accuracy in its flight.

According to the laws of rotatory bodies, the tendency is for the axis of rotation always to remain parallel to its original direction. Hence we have the power of using elongated bullets from rifles; bullets, for instance, of a cylindro-conical form, termed *pickets*. These being made to rotate on their longer axis, constantly present their points to the resistance of the atmosphere, and at the same time that they present an area of resistance of the same size as a spherical bullet of the same diameter, they possess, supposing them to start with the same initial velocity, a much greater momentum to overcome this resistance. Therefore, the retardation being less [GUNNERY], we obtain a greatly increased range. A cylindro-conical picket cannot be fired from an ordinary smooth-bored gun, because, assuming a rotation almost immediately on leaving the muzzle round some of the shorter axes, all advantage is lost.

The tendency of all rotating bodies to rotate round the shortest axis of greatest moments is an important consideration in the construction of rifle pickets. If the cylinder be very long and solid, the tendency is for the bullet to *upset* during its flight. The hollow at the base of most rifle pickets is therefore of great assistance in retaining the impressed rotation. There are two other points connected with the rotation of the picket, which it may be as well to notice before proceeding to the description of the rifle itself.

Fig. 3.



The tendency of the axis of rotation to remain parallel to its original direction is the cause of a peculiar deviation, termed by the French *derivation*. It was pointed out by Robins, that when the elevation of the piece is high, and the trajectory greatly curved, the axis of the bullet, or of rotation, does not remain tangential to the trajectory, but very soon begins to make an angle with it, which angle continues to increase to the end of the range (*fig.* 3); the consequence is, that there is an inequality in the resistance of the air on different sides of the axis; the bullet or picket presents an increased rotating surface to the condensed air, that is, there is a greater resistance from friction on one side (below) the axis of rotation than on the other; the effect of this resistance will, for the reason before given, cause the bullet to deflect or derivate. But this resistance is almost wholly below, and of the same nature as that shown, *fig.* 1, as acting on the anterior hemisphere of the spherical bullet, whilst little or none of the opposing resistance of condensation of air from the meeting of two currents can be called into play (or rather, it will be in a position where it can have little effect) consequently, the bullet or picket, supposing it to have a right-handed rotation from above downwards, viewing it from behind the piece, will have a derivation to the right. The path of the centre of gravity of the shot will be a line of double curvature, but the axis of rotation will remain constantly parallel to its original direction. Robins proposed that the bullets should be formed like eggs, the longer axis being placed in the direction of the axis of the piece, and the larger end to the front, in order that, the centre of gravity being forward, the greater resistance of the air acting behind might throw the point down, and constantly keep the axis tangential to the trajectory. More recently, *canelures*, grooves cut round the base of a cylindro-conical bullet (see *fig.* 6), have been proposed by M. Tamissier, and employed with the same object. But a slight consideration will show that the action of this increased resistance behind the centre of gravity is not simply a force tending to produce angular motion in the axis of the bullet in the plane of the trajectory round an axis perpendicular to it, but is of the nature of the action arising from the friction of the rotating bullet or picket, when its axis is inclined to the trajectory, and which we have just been discussing. But it must be remembered, that we were then assuming either that the resistance of the atmosphere was equal on both sides of the centre of gravity, or that any slight inequality there might be was not sufficient to overcome the effect of rotation in keeping the axis parallel to its original direction; whereas now, from the object of the canelures, in order that they may be effective, we must assume that the increased resistance behind the centre of gravity is sufficiently great to give angular motion to the axis of rotation. For the same reason, then, that the bullet or picket would in the former case deflect to the right, supposing it to have a right-handed twist, in this case the portion behind the centre of gravity would deflect more, proportionately to the greater resistance on it, than the portion in front; that is, the axis or head of the bullet must turn to the *left*, making an angle with the plane of the trajectory. In this position the combined forces will tend to depress the head, and so on, if we consider it in its successive positions, with the forces acting on it, we shall see that the effect of the increased resistance behind the centre of gravity will be to make the bullet assume a second motion of rotation—one motion of rotation, the original one, being round the longer axis, while the second will be round an axis making an angle with this, and directed to the left of the tangent of the trajectory at every moment;—though the deflection from this oblique surface would be to the left, and counteracting the deflection it was intended to counteract, yet the *wabbling* motion the bullet must assume would be very destructive to accuracy and penetration. When from the form of the bullet the resistance is greater in front of the centre of gravity, and sufficient to give angular motion to the axis of rotation, the second axis of rotation will be directed to the *right* of the tangent of the trajectory, and there will be increased deflection to the right.

These effects may be proved experimentally with the gyroscope. It is, therefore, better, as the derivation when the axis of rotation remains parallel to its original direction is pretty constant for the same distances, to allow for it when laying the gun, than to try and correct it by the form of the shot.

Another curious effect arising from the action of rotation, tending to keep the axis of rotation parallel to its original direction, is, that at certain low elevations the range of the elongated projectile is absolutely greater in the atmosphere than it would be in vacuo. This is evidently a point of great importance practically. It is thus explained by Sir W. Armstrong: "In a vacuum, the trajectory would be the same, whether the projectile were elongated or spherical, so long as the angle of elevation and the initial velocity were constant; but the presence of a resisting atmosphere makes this remarkable difference, that while it greatly shortens the range of the round shot, it actually prolongs that of the elongated projectile, provided the angle of elevation do not exceed a certain limit, which in my experiments I have found to be about 6°. This appears at first very paradoxical, but it may be easily explained. The elongated shot, if properly formed, and having a sufficient rotation, retains the same inclination to the horizontal plane throughout its flight, and consequently acquires a continually increasing obliquity to the curve of its flight. Now the effect of this obliquity is, that the projectile is in a measure sustained upon the air, just as a kite is supported by the current of air meeting the inclined surface, and the result is, that its descent is retarded so that it has time to reach to a greater distance."

The following example, to prove the truth of this statement, is taken from 'Elementary Lectures on Artillery, R. M. Academy,' by Major Owen, R.A., and Captain Dames, R.A., from which also some of the figures are taken: "The initial velocity of the projectile from Sir W. Armstrong's 12-pr. gun is said to be 1080 feet per second; what would be its range in vacuo when fired at 2° of elevation?

$$R = \frac{v^2 \times \sin 2a}{g} = \frac{\overline{1080}|^2 \times \sin 4^\circ}{32} = \frac{1166400 \times \cdot 069}{32}$$
$$= 2515 \text{ ft. or } 838 \text{ yds.}$$

If 1100 be taken as the velocity, 880 yards would be the range. From the table of ranges given in the 'Manual of Artillery Exercises,' 980 yards is the range obtained with this gun at an angle of 2° of elevation. The range of the projectile in the air exceeds therefore that in vacuo by about 140 yards, if the initial velocity is 1080 feet a second, and by 100 yards should the velocity be 1100 feet a second." A 32-pr. shot fired at an angle of 2° with a velocity of 1600 feet per second, ranges less than ⅓ of the distance it would range in vacuo.

The interior of a rifle barrel is a cylinder, with a certain number of grooves cut in it; these grooves are parallel to one another, but make an angle with the axis of the cylinder or barrel—that is, they are disposed spirally round it. The bullet fitting these, when forced through the barrel by the action of the powder, acquires a motion of rotation round the axis of the piece in addition to the motion of translation, and this motion it of course retains after leaving the piece. The rifle barrel is in fact a female screw, and the action is the same as that of a nut through which a screw is driven by pressure.

The elements of a rifle may be considered to be a cylinder, grooves, bullet, and method of making the bullet fit the grooves or take the rifling. No rules for these various points have at present, at all events, been established; though perhaps Mr. Whitworth in his experiments has done more than anyone else to establish some of them on a scientific basis. But at present the diameter of the cylinder, that is, the bore; the number, and depth, and inclination of the grooves; the form and weight of the bullet, and the method of making it take the rifling—vary with every nation, and indeed with almost every gunmaker. We can therefore merely attempt to give some description of one or two of the most general forms of rifle. Before doing so, however, it may be as well to consider what are the points to be borne in mind, or what are the conditions of the problem of constructing a perfect rifle. This will assist us in coming to a conclusion as to what rifle combines the before-mentioned elements in the best proportions.

1st. The action of a rifle being the same as that of a nut on a screw driven through it, the action of the powder on a bullet in a rifle barrel must be the same as that of a pressure moving a body up an inclined plane, the direction of the pressure being parallel to the base. The greater the inclination of the plane, the less the velocity in the direction of the pressure generated in the body in its passage over a given space in the same direction, because of the greater inclination of the plane, and also because of its thereby increased friction.

In the rifle, therefore, the greater the inclination[*] of the grooves, the less will be the initial velocity due to a given charge. Hence the inclination of the grooves should be the least that will effect the purpose; that is, that will give the bullet sufficient rotation round its axis to retain it parallel to its original direction during its flight. This inclination, as given in 'Straith's Artillery,' by Cook and Hyde, is—

Enfield	1° 19′ 11″
Jacob's	2° 30′ 0″
Whitworth's	4° 3′ 0″

With respect to the form to be given to the grooves in section, and their number, it is evident that the main consideration on which they depend is the manner in which the projectile takes its rifling. If it is by the expansion produced by the explosion, it is evident that they should be wide and shallow, rounded and not angular, while the groove or furrow on one side is opposite the projection or land on the other side. The Enfield rifle, described further on, with its three wide, shallow, rounded grooves, fulfils these conditions. If on the other hand the projectile takes its rifling by being forced into a narrower bore, as in the breech-loaders, it is evident that the cutting portions, the lands, should be narrow, the grooves not very deep, not deeper than will just suffice to give a sufficient hold, with sharp angles and square sides at least on one side. The Armstrong gun [RIFLED ORDNANCE], with its numerous narrow lands and furrows, is made in this way.

If the projectile is formed to fit the grooves for convenience in loading, they and the projections on the projectile to fit them should be made prominent and well marked, as in the two-grooved rifled Jacob's or Whitworth's. This last mentioned form, however, is also well adapted for an expanding ball, and while it gives a perfect hold on the projectile reduces friction to a minimum.

2nd. The picket should be as long in proportion to its diameter as possible; for, *cæteris paribus*, the longer and thinner the projectile is, the greater will be its range and accuracy. But at the same time it must be remembered that, first, especially for military rifles, there are great objections to a very small bore and attenuated picket: the former being difficult to clean, the latter liable to injury, and requiring a long fragile cartridge. Secondly, the inclination of the grooves is necessarily increased, in order to give the picket sufficient rotation; which, besides being objectionable for the reasons before given, renders the bullet liable to strip, especially with the soft metal required in expanding bullets. Thirdly, the bore may be so diminished as to prevent the power of giving the picket sufficient initial velocity; that is to say, that, given the calibre, there is a limit beyond which it is detrimental to increase the length and consequent weight of the projectile, on account of the mechanical distribution of the charge.

3rd. There are certain mechanical considerations: among which are a barrel of sufficient weight, perfectly true bore, with accurately parallel grooves brought to a high state of smoothness; and, when the rifling is taken by an expanding bullet, the distribution and depth of the grooves such as will allow of their being perfectly filled. Three wide shallow grooves appear the best, as in the Enfield rifle. Rifles with *gaining twists*, that is, a spiral increasing in inclination from breech to muzzle, have been tried. In fact the Lancaster rifles, with which the Royal Engineers are armed, are of this description; these have made good practice, but it may be only from superior manufacture, for it is evident that there is nothing gained, but, on the other hand, when the projectile is long, there is a constant alteration of form, causing increased resistance. These various points require a long series of carefully conducted experiments to arrive at any absolute rules.

Commencing with the greatest weight of bullet, on account of recoil, that it is possible for a man to fire from his shoulder, and investigating how far the greatest advantage in each direction may be obtained, compatibly with the conflicting considerations, is the only manner in which a perfect rifle can be formed. We believe that this is the manner in which Mr. Whitworth arrived at his proportions, and his is certainly the most perfect weapon yet produced.

The first form of rifle employed in the British service was a seven-groove rifle. The method of loading was this: after pouring in the requisite charge, a greased patch (a circular piece of cotton, about twice the diameter of bore) was placed on the muzzle; a spherical bullet, slightly larger than the bore of the gun, was then placed on it and forced down with an iron ramrod and wooden mallet. Thus the portion of the bullet in contact with the bore became indented, and received its rifling; it was, however, a long and tedious process, not well adapted for military purposes. It was superseded by the two-grooved rifle and belted ball; the grooves were wide and deep, and the bullet, which was sewn into a thin piece of calico, had a projecting zone fitting them. This form was easier to load, and gave pretty good practice up to 300 yards, but it had the disadvantage of windage, and after a time fouled.

Robins had pointed out the advantages of a breech-loading rifle, in giving ease in loading:—"As both these methods of charging at the mouth take up a good deal of time, the rifled barrels which have been made in England (for I remember not to have seen it in any foreign piece) are contrived to be charged at the breech, where the piece is for this purpose made larger than in any other part; and the powder and bullet are put in through the side of the barrel by an opening, which, when the piece is loaded, is filled up by a screw. By this means, when the piece is fired, the bullet is forced through the rifles, and acquires the same spiral motion as in the former kind of pieces. And perhaps somewhat of this kind, though not in the manner now practised, would be, of all others, the most perfect method for the construction of these barrels."

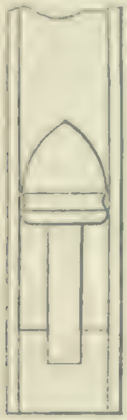
---

[*] The inclination of the grooves, commonly called the twist, is generally given as one turn in so many feet. This of course gives no information directly as to the proportionate inclination of the grooves in two rifles of different calibre. The correct estimate of this, is the angle of inclination of the line, showing the groove on the *developed* surface of the bore of the piece, that is, by comparing the lengths in which one turn is effected with the circumferences of the bores. This may easily be done, when we know the calibres or bores, by laying off on a line the length in which one turn or twist is completed, then laying off at right angles to this the circumference of the bore. Completing the rectangle gives the developed surface, of which the diagonal is the groove, and the angle it makes with the side of the rectangle, the angle of inclination.

This process has been carried out very successfully in the Prussian needle-gun, and various other breech-loading muskets, and in the Armstrong gun. [RIFLED ORDNANCE.] Though space will not permit of our describing the needle-gun, we may mention that there is no nipple and cap used, but the detonating powder being contained in a wooden sabot at the base of the bullet, a needle is driven forward by the lock on the trigger being pulled, and forcing through the powder in the cartridge, ignites the detonating powder at the other end. The needle being very liable to injury, a form of cartridge with the detonating composition at the back of the charge has been adopted successfully. Breech-loaders, besides increasing the rapidity of fire, enable the soldier to load without exposing himself whilst doing so, which is sometimes a great object, as, for instance, in a square.

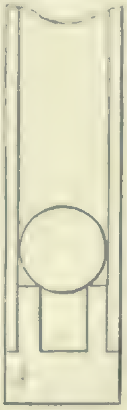
To return to muzzle-loaders. In 1827, M. Delvigne, a French officer, proposed to increase the facility of loading by giving the rifle a chamber, as *fig.* 4; the bullet being smaller than the bore is easily loaded, and when on the chamber a few smart blows with the ramrod expands it into the grooves. It did not, however, succeed well on service, for powder lodged on the shoulders of the chamber and the rifle fouled. In 1842, Colonel Thouvenin, also a French officer, invented the "carabine-a-tige," see *fig.* 5. The action is the same as with the Delvigne chamber, and needs no explanation. It answered better, but there were many disadvantages. The bullet in both cases is knocked out of shape. The tige, or steel stem, is liable to injury, and from its position takes up much space, elongating the charge and placing it at a mechanical disadvantage in its ignition. M. Delvigne then proposed the elongated bullet, as shown in *fig.* 5, which was a great improvement, and it was introduced into the French service with the carabine-a-tige.

Fig. 4.



Section.

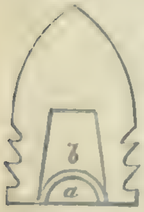
Fig. 5.



Section.

M. Minié then proposed an expanding bullet, of the form shown in *fig.* 6, with an iron cup or plug *a*, in the hollow base *b*. This remedied all the disadvantages of the carabine-a-tige. The bullet can be easily rammed down, and the iron cup having a less specific gravity than the lead is driven forward by the explosion and assists in expanding the bullet. It is but justice to Captain Norton to state that he proposed an expanding bullet on the same principle many years before. It is, however, not absolutely necessary to have a hollow base and plug in order to make the bullet expand. A hollow base alone, or indeed a solid cylinder, if long enough, will expand, though not quite so much. The powder acting like a blow drives the base forward before the inertia of the fore part is overcome, and expands it at the shoulder.

Fig. 6.



Section.

A rifle on the Minié principle was adopted into the English service in 1851. In 1852 Lord Hardinge appointed a committee to investigate the question of rifled arms, and they in 1853 adopted a modification of the bullet and arm proposed by Mr. Pritchett. *Fig.* 7 shows the bullet first adopted, without a plug. This bullet, having only a slight windage, was found to foul. One with a boxwood plug and greater windage was then adopted. *Figs.* 8 and 9 show the bullet; and *fig.* 10 the cartridge. The cartridges may be made with two different pieces of paper, one thicker than the other; but the best form is made of two seamless bags. Into the larger the bullet is forced base foremost to the bottom, the smaller is then pushed in on to the point of the bullet, and filled with powder, the ends pasted up, and the base round the bullet dipped into a lubricator, a mixture of tallow and bees' wax. In loading, the end of the cartridge is opened and the powder poured in, the bullet is then reversed into the muzzle; when down to the shoulder, the upper portion of the cartridge paper to where the inner case comes down to, is torn off, and the bullet pushed down with the ramrod. This is incomparably the best arm that any troops have *yet been armed with*, though it may not be the best weapon invented. It is wholly made by machinery, at least all those manufactured at the Government factory at Enfield (whence its name). This gives it the great advantage for a military weapon, besides perfection in accuracy, of having all its parts interchangeable with other arms of the same construction. The dimensions, &c., of the Enfield rifled musket are—

Fig. 7.

Fig. 9.

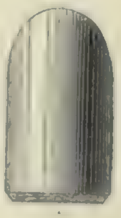

Fig. 10.

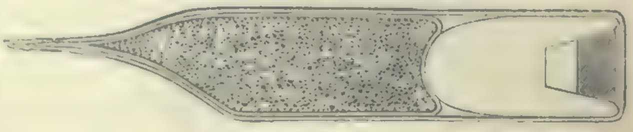

Section.

Weight, with bayonet	9 lbs. 3 oz.
Barrel, weight	4 lbs. 2 oz.
Length	3 ft. 3 in.
Bore, cylindrical diameter	·577 in.
3 grooves, uniform twist, one turn in . .	6ft. 6 in.
Inclination, therefore	1° 19′ 11″
Width of grooves	·262 in.
Depth at breech	·015 in.
„ at muzzle	·005 in.
Lock swivel—	
Mainspring, draws at half-cock	15 lbs. to 16 lbs.
Sear spring draws	7 lbs. to 8 lbs.
Pull of lock	13 lbs. to 14 lbs.
Trigger draws	7 lbs. to 8 lbs.
Charge, powder 2½ drams, F. G.	
Bullet, expanding, with box-wood plug—	
Diameter, formerly ·568 in., now reduced to .	·55 in.
Length	1·05 in.
Weight	520 grains.
Weight of 60 rounds of ammunition, with caps	5 lbs. 8 oz.
The Old Musket, with a bore of ·753, weighed .	11 lbs. 3 oz.
And the ammunition	6 lbs. 10 oz.

Good practice may be made with the Enfield up to 900 yards, to which distance it is sighted. The above are the dimensions of what is called the Long Enfield—there is a shorter arm for the Rifles, &c., the dimensions of which it is not necessary to particularise. A sword bayonet is used instead of the ordinary bayonet, but for many reasons it is more than doubtful whether the short rifle, with the accompanying awkward sword, is a more appropriate weapon. The cavalry are

Fig. 11.

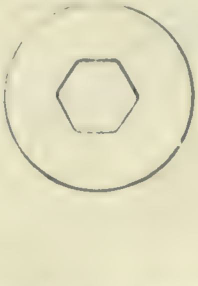

Fig. 12.

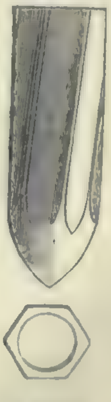

Fig. 13.

armed with a Sharp's (breech-loading) carbine, and also some, we believe, with Westley Richards's.

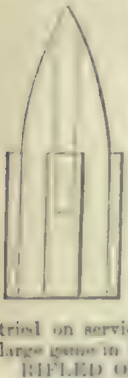
Mr. Joseph Whitworth, the eminent machine manfacturer of Manchester, has invented and patented an admirable rifle: a section of the barrel is represented in *fig.* 11; and the bullet, with a plan of base, in *fig.* 12. The bore is a hexagon in plan, or rather in cross section, with the angles rounded off, the diameter of inscribed circle being only ·45 inch. The bore is described by this hexagonal section moving from one end to the other, and rotating uniformly round the axis of the piece, so as to complete one rotation while passing along 20 inches: that is, that the grooves, if we may so term them, make one turn in 20 inches. The pickets are either of the form shown in *fig.* 11, or as shown in *fig.* 13, that is, cylindrical, and of a rather less diameter than the inscribed circle, when they are expanding. The former have the advantage of allowing the use of a hard metal (9 parts lead, 1 part tin), and consequent great penetration. By *easing off* the *edges* that *bear* in loading, the former description of bullet is easily rammed down, whilst as the bearing is thrown on the other edges as it is being driven out, almost all windage is stopped.

A trial took place in April, 1857, between these rifles and the Enfield, at Hythe School of Musketry; the experiments have been objected to on various grounds, but it may be as well to give the results:—

Rifle.	Range in yards.	Elevation.	Figure of Merit.
		Degrees.	
Whitworth . .	500	1·15	0·37
Enfield . . .		1·32	0·24
Whitworth . .	800	2·23	1·0
Enfield . . .		2·45	4·11
Whitworth . .	1100	3·45	2·41
Enfield . . .		4·12	8·04
Whitworth . .	1400	5	4·62
Enfield . . .		6·20 to 7	No hits.
Whitworth . .	1880	6·40	11·62
Enfield . . .		..	..

The figure of merit is the mean radial distance in feet from their centre of 10 shots fired from a rest table. A Whitworth bullet, with the service charge of 2½ drachms of powder, penetrated thirty-three ½-inch planks of elm, and was only stopped by a solid balk of timber behind them. Mr. Lancaster's rifle, which has before been mentioned, has a gaining twist; the section of the bore is an ellipse; the bore is formed by this ellipse moving along the axis of the piece at the same time that it rotates round it, rotating, not uniformly, but more rapidly as it comes towards the muzzle. The rifles with which the Royal Engineers are armed, on this principle, take the same ammunition as the Enfield, and make good practice up to 1000 yards.

Fig. 14.



The last rifle we need mention is that invented by General Jacob. The form of bullet is seen in *fig.* 14. The grooves are of considerable depth, four in number, and are as wide as the lands. The diameter of the bore is the 32 gauge. The picket is solid, and has four projections to fit the grooves. The grooves make one turn in 36 inches. General Jacob made many experiments with shells from his rifles. These shells had been invented many years ago by Captain Norton, and having improved upon them, General Jacob made a most formidable weapon, exploding ammunition waggons at 1600 and 1800 yards distance. The picket is cast with a cylindrical cavity in its conical end, into the cavity is inserted a copper tube, filled with fine-grain powder, and primed at the point with a detonating composition. These shells may be very useful, though they have never yet been tried on service, but they have been found very effective against large game in India and Africa.

RIFLED ORDNANCE. In the year 1774, Captain Blair proposed the formation of rifled guns of iron, to be used as field artillery. Agreeably to the old practice, they were to be made hollow in the act of being cast, and in the same operation the grooves were to be formed. The balls were to be of lead, with knobs on them to fit the grooves, and they were to weigh not more than two pounds. About the beginning of this century, the French attempted to introduce into their service cannon shot of a cylindro-spherical form, the cylindrical part being in contact with the charge of powder, and a ring of lead surrounding the shot near its middle, so as to render this part rather greater than the bore of the gun. The circumference of the ring being scraped down by the edge of the muzzle when the shot was forced into the gun, became in close contact with the surface of the bore, and thus no windage was left. By this contrivance it was expected that most of the advantages of a rifled gun would be obtained, though no rotatory motion took place in the shot. The result of the trials was thought to be favourable with respect to the direction and range of the shot; but the labour and time required to load the gun were great, and this circumstance probably prevented the invention from being adopted.

In 1846, Major Cavalli, of the Sardinian Artillery, invented a rifled gun; and about the same time another was proposed by Baron Wahrendorff, a Swede. Both were two-grooved breech-loading pieces. In 1850 these guns were experimented with at Shoeburyness against the service 32-pounder of 56 cwt. The weight of the elongated projectile for both guns was about 64 or 65 lbs. Space does not permit of our entering into a description of them; but some remarks of Sir H. Douglas on the result of the experiments may be quoted:—"At the efficient service elevation of 5°, with charges of 8 lbs., the ranges, and also deflections, of the different projectiles were nearly equal to one another; and the like is true with charges of 10 lbs. At elevations of 10°, the ranges of the foreign guns exceeded those of the English 32-pounders, with charges of 8 lbs., by 380 yards, and with charges of 10 lbs. by 690 yards; and at elevations of 15° the excess was, with charges of 8 lbs., about 790 yards, and with charges of 10 lbs. about 1100 yards." The deviations, which were always in the direction of the rotation of the projectile, were so variable that no allowance could be made for them. The Wahrendorff gun had considerable advantages in length of range over the 32-pounder at high elevations, but the practice was then very uncertain. After four rounds, the Cavalli gun became unserviceable by the copper ring embedded in the metal of the gun at the bottom of the bore being damaged. The attempt to repair this was unsuccessful, for, on a further trial, the whole breech was blown away. The Wahrendorff gun, however, stood well.

The next rifle gun invented was that by Mr. Lancaster. It was tried at Shoeburyness in 1851. The principle was similar to that of the rifle [RIFLE]—an elliptical bore, with a gaining or increasing twist. In fact it was a two-grooved rifle, with the angles of the grooves chamfered off. The friction in the bore was so great that it was necessary to make the projectile, which was cylindro-conoidal with an elliptical section, of wrought iron. This was the first rifled cannon ever used in war, and was employed by the English in the Crimea, both on board the gun-boats and in the batteries, against Sebastopol. Though good results had been obtained in 1852 at Shoeburyness, with spheroidal projectiles from these guns, they did not succeed well on service. The trial was certainly hardly a fair one, many of the guns being light 8-inch, bored up; and these burst. Some of the heavy 8-inch Lancaster guns, however, also burst with the elongated projectile, we believe. Those who worked the guns had in many cases not been instructed in their use; and Mr. Lancaster has accounted for the shells constantly bursting in the bore by the welding of the two pieces of wrought iron with which they were made not being a perfect joint, and the explosion of the gun communicating to the interior of the shell. But it is most probable that the shell jammed in the bore, which it was very likely to do from its form and the increasing twist. Certain it is that the practice was very uncertain, and the result not satisfactory.

Under the heads of GUNNERY and RIFLE we have considered the points to be attended to in the formation of rifle arms and projectiles. These are equally applicable to ordnance. But when we come to the manufacture of very large guns, either smooth bore or rifled, we meet with a difficulty in making them sufficiently strong to resist the effect of the explosion of the charge. This difficulty arises as we increase the diameter of the bore much sooner in rifled pieces than in smooth bores, because in the former there is a greater resistance to the motion of the projectile in the bore, while at the same time the elongated projectile employed is of greater proportional weight. It has been however found very difficult to make solid shot guns—that is, when heavy charges are employed—of a greater diameter of bore than 8 inches (the 68-pounder); and in the war with Russia it was found that the 13-inch mortars, even the immensely heavy sea service ones, constantly burst after heavy firing, as at Sweaborg.

This can be easily understood when we remember that, in guns of the ordinary construction, it is useless to increase the thickness of metal beyond a certain limit, and that to produce equal initial velocities in two similar projectiles of different diameters—as, for instance, two spherical shot of 2 and 4 inches diameter—the pressure or strain on the metal of the gun increases in a ratio much higher than the ratio of the surfaces of the bores. To make the first point clear, if we take the transverse section of a gun, which is an annulus, we may consider it composed of a series of concentric rings, and the strain of the explosion a statical force, though it is of the nature of impact. That the metal of the gun is, as might be supposed, extended by the action of the powder at the moment of explosion (some portion of which extension, from want of elasticity, is permanent), may be proved experimentally; that is to say, the diameter of the annulus or transverse section is increased, but the area of the annulus must remain the same, and therefore the width of the annulus must diminish, or, which is the same thing, the circumference of the inner circle must increase in a greater ratio than the outer. Hence the greater the distance of any of the rings composing the annulus from the centre or axis of the gun, the less will it be stretched, and the less will be the strain on it, and the resistance to a pressure of any two rings will be inversely as the squares of their distances from the axis.

Now iron extends with a tensile strain, and the extension is more than proportionate to the strain; that is, the resistance to extension is only at first nearly proportionate to the extension. It is found, by experiment, that for wood and wrought-iron the resistance to extension in each fibre is at first nearly proportional to the extension. Mr. Hodgkinson found that in cast-iron the resistance to extension was less than a quantity proportional to the extension by a quantity nearly proportional to the square of the extension. If w represent resistance to extension, and e the corresponding extension, $w = ae - be^2$.

It is therefore evident that at a certain thickness of metal the cohesion or tensile strength of the inner ring may be overcome, and the ring burst before the outer ring receives any strain, and therefore it is useless to increase the thickness of metal beyond the point at which the force exerted on the surface of the bore is sufficient to rupture it before the strain acts to any extent on the exterior. With respect to the second point, taking two spherical bullets of 2 and 4 inches diameter, *cæteris paribus*, the pressure required to give them the same initial velocities will be as their weights, that is, as the cubes of their diameters, but the surfaces of the bores will only increase as the squares of the diameters, and therefore with larger calibres the strains on the guns will be greatly increased.

In order to obtain the requisite strength in rifled ordnance (especially in those of a large calibre), where the strain is again increased by the resistance to motion offered by the rifling, it is necessary to adopt some means of equalising the strains through the metal. Different ways of effecting this have been suggested. The object of all of them is to give a certain *initial* tension to the outer rings—the exterior having the greatest, and the tensions decreasing and resulting in compression in the interior. The rings can be shrunk on to an interior cylinder or core, that is, put on hot and then cooled, or they may be put on by hydraulic pressure, or the core or tube may be bound round with wire, gradually increasing the strain of each layer. Captain Blakely, R.A., who appears to have investigated the subject fully, made a gun in this last manner, which stood some most severe trials at Shoeburyness, in 1856 and 1857. The ancient built-up guns, such as Mons Meg, were often made with longitudinal bars, kept together with rings shrunk on. This process was evidently adopted on account of the imperfect state of manufacturing power, as there could be no use in not having the interior a homogeneous cylinder. A huge mortar of 36 inches diameter was, however, made in this way a few years ago by Mr. Mallet, and failed.

In 1854 Sir W. Armstrong brought forward a breech-loading rifle-gun, his plan was accepted, and a gun of small calibre having been made according to it, was tried at Shoeburyness. With some modifications this description of gun has been adopted in the British service, and found very efficient in the late China war. In fact it is the most perfect gun yet adopted in any artillery. The following description of the original gun tried at Shoeburyness, and at Sir W. Armstrong's private factory at Newcastle, is taken from the minutes of 'Proceedings of the Royal Artillery Institution,' given in the 'Elementary Lectures on Artillery for the Royal Military Academy,' by Major Owen, R.A., and Captain Dames, R.A.; from which also, and a paper on the 'Construction of Artillery,' printed by the Institution of Civil Engineers, the description and drawings of gun, shell, &c, are taken:—

"A core or internal lining was formed of cast-steel, to which the requisite strength was given by encircling it with twisted cylinders of wrought-iron made in a similar manner to gun barrels, and tightly contracted upon the steel core by the usual process of cooling after previous expansion by heat; the parts are then in a state of initial tension, which is necessary to bring their entire strength into operation. The arrangement for loading at the breech consists of a powerful screw having a hole through the centre in the prolonged axis of the bore, through which hole the bullet and charge are delivered into the gun. A "breech-piece" with a mitred face fitting a similar face at the end of the bore, is dropped into a recess, and by the action of the screw pressed tightly into its seat, so as to effectually close the bore. The fitting surfaces which close the bore were at first made of unhardened steel: this failed; hardened steel was next used, but this yielded to the action of the powder more rapidly than before; copper was then tried, and no further difficulty was experienced. The breech-piece contains the vent. The bore of the gun was 1¾ inches in diameter, and contained eight spiral grooves, having an inclination of one turn in 12 feet; these grooves terminated at a distance of 16 inches from the breech, and the bore then gradually expands in a length of 3 inches from 1¾ inch to 1⅞ inch in diameter." The gun weighed about 5 cwt.

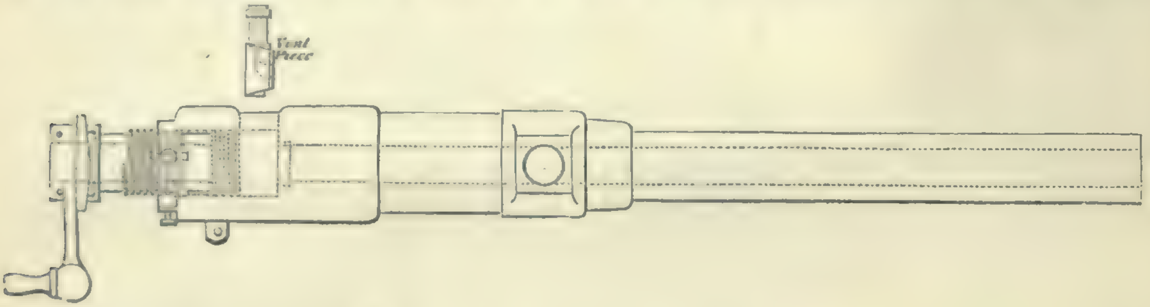


Fig. 1.—Armstrong Gun, scale ¾ inch to 1 foot ($\frac{1}{16}$).

The projectile, which is cylindro-conoidal in form, was 6½ inches long, and weighed 5 lbs.; it was of cast-iron coated with lead, and was hollow, so as to be used either as shot or shell. It was slightly larger in diameter than the bore of the gun, and being inserted at the breech took its rifling by being forced through the grooved bore.

The charge was one-eighth weight of shot. The following results of experiments are given in the 'Lectures' before mentioned:—Fourteen projectiles were fired at a butt of wood 5 feet wide and 7½ high from a distance of 1500 yards. Six shots were fired as trial shots to obtain the correct elevation. The remaining eight hit the butt without grazing, the elevation of the gun being 4° 26′, and the mean deflection from the centre line on the butt was only 11½ inches. The experiments with shells fired at two targets, placed 30 feet apart, covering one another, were equally remarkable—nearly all the shells passing through the first target and bursting before reaching the second.

This being a small gun was of course easy of manufacture, but Sir W. Armstrong has been equally successful in making 12, 25, 32, and 40 pounders; and experiments are now being made with much heavier guns, 70, 80, and 100 pounders.

The 12 pounder is the gun adopted for the field batteries and horse artillery. Those used in China have weighed 6 cwt., with a charge of 1 lb. 6 oz. It is probable that in future the 8 cwt. gun, with a charge of 1 lb. 8 oz., will be adopted. The guns are now made wholly of wrought iron, and in order to avoid the difficulty of forging very large masses they are made in pieces, tubes from 2 feet to 5 feet long, which are then welded together. The tubes are formed by winding long bars of heated iron round a roller, the coil is then brought to a welding heat and hammered together; the edges of the coils or tubes having been bevelled off, the tubes are welded together. The manufacture is very complicated. The finished gun is shown in *fig.* 1. The grooves are very narrow and shallow. The driving sides, that is to say, the sides the projectile bears on in passing out of the gun, are cut square, or at least radial, the other edges are rounded off.

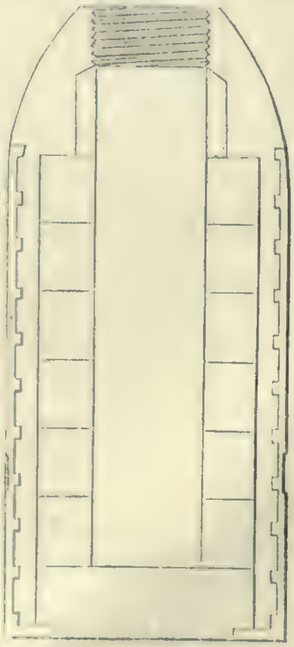

Fig. 2.—Armstrong Shell, scale ½.

The width of the lands and grooves being the same, they vary in number according to the calibre of the piece,—the 12 pounder has

34, the larger guns have more, -they make about half a turn in the length of the piece, and the charge seems to be about ⅛th the weight of the projectile. The construction of the projectile, which is shown in *fig.* 2, has been thus described by Sir W. Armstrong. "The projectile consists of a very thin cast-iron shell, the interior of which is composed of forty-two segment-shaped pieces of cast iron built up in layers around a cylindrical cavity in the centre, which contains the bursting charge and the concussion arrangement. The exterior of the shell is thinly coated with lead, which is applied by placing the shell in a mould and pouring melted lead round it. The lead is allowed to percolate among the segments, so as to fill up the interstices, the central cavity being kept open by the insertion of a steel core. In this state the projectile is so compact that it might be fired through 9 feet of hard timber without injury, while its resistance to a bursting force is so small that less than one ounce of powder is sufficient to break it in pieces." It is a great advantage for service to have a projectile of this description, which can be used as shot, shell, shrapnell, or case. The simplicity of ammunition is perfect when one form serves all the purposes that can be required, for it is only necessary in using it as shot not to put in a fuze. The shell can, as will be seen, be made, according to the fuze, either a *time* shell or a *concussion* shell. By adjusting the fuze so as to burst the shell just short of the object, we have a shrapnell of the most perfect description, for a small bursting charge will liberate the numerous segments of which the shell is formed; while, by adjusting the fuze so as to burst the shell at the muzzle, we may use it as case. Sir W. Armstrong stated in a speech he made at Newcastle, that the shell burst into 49 regular pieces and about 100 irregular pieces. And also that for breaching purposes, firing at buildings and ships, a different construction of shell was adopted, the object being to introduce the largest possible charge of powder. The shell of the Armstrong 32-pounder contains about twice as much powder as that of the ordinary 32 pounder.

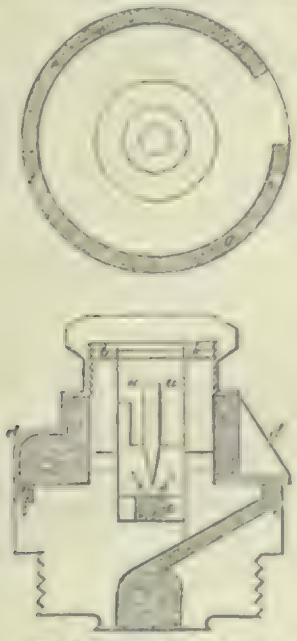

Fig. 3.—Time Fuze, full size.

a a, the hammer; *b b*, the suspending pin; *c*, the detonating composition; *d d*, the hollow collar; *e e*, the fuze composition.

The two descriptions of fuzes, *figs.* 3 and 4, are thus described by Sir W. Armstrong. "The body of the time fuze, *fig.* 3, is made of a mixture of lead and tin, cast to the required form in a mould. The fuze composition is stamped into a channel forming nearly an entire circle round the body of the fuze, and is afterwards papered and varnished on the external surface. As the shell fits accurately into the gun, there is no passage of flame by which the fuze could be ignited. The effect is therefore produced in the following manner — A small quantity of detonating composition is deposited at the bottom of the cylindrical cavity in the centre of the fuze, and above this is placed a small weight or striker terminating in a sharp point presented downwards. This striker is secured in its place by a pin, which, when the gun is fired, is broken by reason of the *vis inertiæ* of the striker. The detonator is then instantly pierced by the point and is thus fired. The flame thus produced passes into an annular space formed within the revolving cover, which rests on the upper surface of the fuze composition, and from this annular space it is directed outwards through an opening, so as to impinge on and to ignite the fuze composition at any required part of the circle. The fuze thus ignited burns in both directions, but only takes effect at one extremity, where it communicates with a small quantity of powder in the centre. The fuze is surrounded by a scale paper graduated to accord with the elevation of the gun, so that when the range of a distant object is found by trial, it is only necessary to turn the igniting aperture of the cover to the point on the fuze scale corresponding with the degrees and minutes of elevation on the tangent scale.

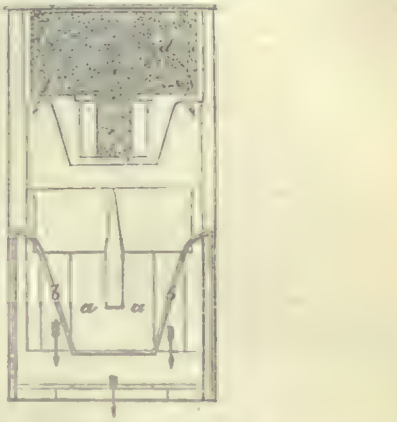

Fig. 4.—Concussion Fuze, full size.

a a, the hammer; *b b*, the suspending pin; *c*, the detonating composition; *d d*, priming chamber.

The concussion fuze (*fig.* 4.) is on nearly the same principle. "A striker with a point presented upwards is secured in a tube by a wire fastening, which is broken on the firing of the gun; the striker being thus liberated recedes through a small space, and rests on the bottom of the tube, but as soon as the shell meets with any check in its motion, the striker runs forward and presses the detonator in front, by which means the bursting charge is ignited." To show the extreme accuracy of the Armstrong shell and fuzes, we may mention an experiment which took place before the Duke of Cambridge and a number of distinguished officers. Two targets, each of 9 feet square, were placed at a distance of 1500 yards from the gun, and 7 shells were fired at them; the effect of these 7 shells was, that the targets were struck in 596 places. Similar effects were produced at 3000 yards with shells, and a target 9 feet square has been struck with shot 5 times out of 10 shots. At 600 yards an object the size of the muzzle of a gun can be struck almost every time with the shot or shell. The tabular statement below will explain the advantages of rifled ordnance at long ranges, while the short ranges at low angles of elevation will be easily understood, for the reasons given under GUNNERY and RIFLE, when we remember that the initial velocity of the Armstrong 12-pounder shot is less than 1100 feet per second, while that of the ordinary 12-pounder is about 1800 feet per second.

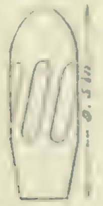
	Ranges at Elevations of						
	P. B	1°	2°	3°	4°	5°	6°
12-pounder Armstrong, weight 6 cwt., charge 1 lb. 6 oz. . .	300	600	900	1200	1500	1800	2100
12-pounder service, weight 18 cwt., charge 4 lbs. . .	300	700	1000	1200	1400	1600	1800

The first form of carriage employed for the Armstrong gun was the bracket carriage with recoil slide. The recoil slide is however abolished for field service pieces, though we believe it is intended to employ it still for garrison, siege, and naval guns. The field service carriage is now in form very similar to the old block trail carriage. The trunnions of the gun however rest in moveable trunnion holes. These trunnion holes being connected together by a band of iron, a horizontal motion can be given to them round a centre or pivot between them by means of a bar, which, passing to the rear almost as far as the elevating screw, has motion given to it by a horizontal screw passing through its end. By this means the gun carriage having been brought into the general direction of line of fire, the gun can be most accurately laid by merely turning the handle attached to this screw without further shifting of the carriage.

The following extract from Sir W. Armstrong's speech at Newcastle, will show the great labour it cost him to bring it to perfection, and its great power now as a siege-gun:—"To go back to the commencement of my experiments, I may tell you that they began upwards of four years ago, my first gun having been commenced in December, 1854, and completed early in the following spring; although this gun was constructed upon the same principle as those which I am now making, it did not in the first instance afford satisfactory results. Schemers, whose inventions merely figure upon paper, have little idea of the difficulties that are encountered by those who carry inventions into practice. For my part, I had my full share of such difficulties, and it took me nearly three years of continual application to surmount them. In the height of summer my experiments were for the most part carried on at the sea-coast, between the hours of 3 o'clock in the morning and 6; for after that time people began to move about and were apt to get in the way. At other seasons I availed myself of the wild moors belonging to my friend Mr. Beaumont, at Allenheads, and there I had a hut constructed on a mountain ridge, 2000 feet above the level of the sea. My targets were placed upon the opposite side of a deep valley, where nothing more valuable than grouse or lean sheep ran the risk of being shot; and well it was that such was the case, for I had constructed an instrument for maintaining a fire upon an object (a breach, for example) after darkness had set in, and I used to awaken the denizens of the heath by firing shells at my distant target in the middle of the night; and I may observe in passing that, when this instrument was fully perfected, I was enabled to strike a distant object on a pitch dark night with the same accuracy as in broad daylight. At the end of the three years I had succeeded in bringing to maturity both guns and projectiles. Several new guns had been made on my own responsibility, and considerable expense incurred on experiments; but all my disbursements were refunded by the Government as soon as the results were ascertained."

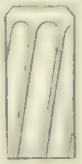
We have entered thus fully into the description of the Armstrong gun as it is the gun adopted in the service. It only remains briefly to notice the Whitworth gun and the French rifled gun. The Whitworth gun has, like the rifle [Rifle], a hexagonal bore, the angles of the hexagon being rounded off. As the projectiles are very long, the inclination of the grooves is very great. The guns with which the experiments were made in the spring of 1860, near Liverpool, were breech loaders. The following description and table of dimensions is taken from the Lectures on Artillery before quoted. "The breech is closed by a cap which screws on outside, and works in an iron hoop attached by a hinge to the side of the breech; the cap is opened back for loading, after which it is shut-to, like a door, and then screwed on to the breech by a handle for the purpose; the vent is in the centre of the cap, and therefore in line with the axis of the bore. For smaller sized guns, Mr. Whitworth uses homogeneous iron, the larger guns are made of the same material, but strengthened with wrought iron hoops fixed on by hydraulic pressure. The Whitworth projectile is hexagonal, its form corresponding to that of the bore, and it is made of cast iron accurately turned by machinery (*fig.* 5); for penetrating hard substances, as wrought iron plates, the projectile is flat headed and made of homogeneous iron (*fig.* 6). The charge is ⅙th the weight of the projectile, and it is placed in the bore in a tin cartridge which remains in until after the gun is fired, when it is removed; a wad of lubricating substance closes the front of the cartridge, and is intended to prevent the fouling of the bore."

Fig. 5.



Maj. axis, 3·1 in.
Minor, 2·8.

Fig. 6.



Whitworth Gun.

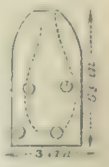
Nature of Gun.	Bore.		Length.	Weight.	Pitch of Rifling.
	Major Axis.	Minor Axis.			
			ft. in.	cwt. qrs.	1 turn in
3-pounder . .	1·6	1·48	6 0	. . .	3 ft. 4 in.
12-pounder .	3·1	2·8	7 9	8 0	5 0
80-pounder . .	5·5	5·0	9 10	80 0	8 4

With the 3-pounders the extraordinary range of 9688 yards (more than 5½ miles) was obtained at 35° of elevation. The Armstrong 32-pounder with the same elevation ranged 9130 yards.

Some of the practice with the Whitworth guns was also very accurate. It also appears to have an advantage over the Armstrong gun in range with equal elevation, and can be used either as a breech loader or as a muzzle loader, while, as explained under Rifle, ease in loading is obtained without windage. But until careful experiments have been conducted with both under the same conditions, which has not been the case hitherto, no decided opinion can be given as to the relative merits. The penetration power of the flat-headed projectile against iron plates is very great, and in fact has been more effective than any other projectile. Mr. Whitworth has found that decreasing the hinder part of the projectile has greatly increased its range.

The French 9-pounder field piece is a muzzle loading 6-grooved bronze gun weighing about 6 cwt. The calibre is about 3·36 inches, the grooves making one turn in 60 inches. The projectile is shown in *fig.* 7. It has 12 leaden buttons on its exterior, that is, 2 for each groove. Though undoubtedly not nearly so perfect a weapon as either the Armstrong or Whitworth, it appears to have done good service in the late Italian campaign. It is also very simple in construction. The French have also a bronze rifled siege gun of about the calibre of 12-pounders, and have rifled some of their heavy iron ship guns. The success of the latter is doubtful, for in all the experiments in this country, unless strengthened, cast iron rifled guns have burst when fired except with very small charges.

Fig. 7.



RIFLEMEN (called by the French *tirailleurs*) were soldiers whose duties corresponded nearly to those of light infantry troops, but their muskets being rifled or grooved, the effect of their fire, within certain limits, was more certain.

In the preceding article we have stated what is known concerning the first use of rifled barrels on the Continent; and in the article Arms it has been shown that the duty of riflemen is indicated in the 'Observations' compiled by the Earl of Albemarle in 1646. The Anglo-American people are, however, believed to have been the first who organised corps of infantry armed with rifle-muskets, and during their struggle for independence the fire from those pieces too often took effect with fatal precision against the officers and in the ranks of the British forces. From that time the incorporation of bodies of riflemen with the armies began to take place among the nations of Europe, and it is now become a general practice. In the British service, the 60th, formerly called the Royal American regiment, is a rifle corps; and Manningham's rifle corps appears in the 'Army List' for 1801, but this became in 1803 the 95th regiment. In 1816 it was formed into the present Rifle Brigade, and placed under the command of Sir David Dundas, who had before been colonel of the 60th regiment. Subsequently to that year a regiment of native riflemen had been raised in Ceylon, and a rifle corps of cavalry at the Cape of Good Hope.

In 1853, after the Minié rifle was adopted into the service, it was intended to arm the whole of the infantry with it. In fact, the greater portion, if not the whole, of our army, were armed with it at the battle of the Alma; but the Enfield rifle having been decided on in 1854 by the committee appointed by Lord Hardinge, the whole of the infantry are now armed with it. Such being the case, the titles of Rifle Brigade and 60th Rifles become meaningless, though still retained on account of old associations.

The 60th and Rifle Brigade are however armed with a short Enfield and sword bayonet.

RIGEL. [Orion.]

RIGHT. This word occurs under some form in all the Teutonic languages; and bears a double meaning equivalent to the significations of the Latin word *jus*.

In its strict sense it means a legal claim; in other words, a claim which can be enforced by legal remedies, or a claim the infringement of which can be punished by a legal sanction. It follows from this definition that every right presupposes the existence of positive law.

The causes of rights, or the modes of acquiring them, are various, and can only be explained in a system of jurisprudence; for example, a person may acquire a right by contract, by gift, by succession, by the non-fulfilment of a condition. But every right co-relates with a legal duty. Thus a right arising from contract (for example, a contract to perform a service, or to pay a sum of money) is a right against a determinate person or persons; a right of property in a field or house is a right to deal with the field or house, availing against the world at large. On the other hand, every legal duty does not co-relate with a right; for there are certain absolute duties which do not co-relate with a right in any determinate person. Such are the duties which are included in the idea of police; as the duties of cleanliness, order, quiet at certain times and places.

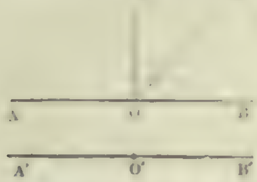
The word right is sometimes used, improperly and secondarily, to signify not legal but moral claims; that is to say, claims which are enforced merely by public opinion, and not by the legal sanction.

In this sense the right of a slave against his master, or of a subject against his sovereign, may be spoken of; although a slave has rarely any legal right against his master, and a subject never has a legal right against his sovereign. It is in the same sense that a sovereign government is sometimes said to have rights against its subjects, although in strictness a sovereign government creates rights, and does not possess them. In like manner, one sovereign government is said to have rights against another sovereign government; that is to say, moral rights, derived from the positive morality prevailing between independent nations, which is called *international law*.

We likewise sometimes hear of certain rights, styled natural rights, which are supposed to be anterior to civil government, and to be paramount to it. Hence these supposed natural rights sometimes receive also the additional epithets of indefeasible, indestructible, inalienable, and the like. This theory of natural rights is closely connected with the fiction of a social compact made between persons living in a state of nature; which theory, though recommended by the deservedly high authority of Locke, has now been abandoned by nearly all political speculators.

RIGHT. (Mathematics.) This term is applied in mathematical language to anything which is imagined to be the most simple of its kind, to distinguish it from others. Thus a right line is a STRAIGHT line; a right angle is the most simple and well-known of the angles used by Euclid: a right cone is one in which the axis is at right angles to the base: and so on.

RIGHT ANGLE. When two lines, at first coincident, are made to separate so that one of them revolves about their common extremity, the revolving line will in time become the continuation of the other. This angle or opening, made by a line and its continuation, would, we might suppose, be one of the principal angles considered in geometry, and should, according to the previously defined meaning of RIGHT, be called a right angle. But in the geometry of Euclid the word angle seems to have been essentially connected with the idea of a pointed corner, and we have no means of finding out that he considered a line and its continuation as making any angle at all. Instead of this angle, made by O A and O B, or the angle of opposite directions, he introduces its half, and calls it a right angle. Let A O C and C O B be equal angles, that is, let O C bisect the angle A O B, and each half is called a right angle. When the angle A O B is mentioned, it is as two right angles. All that is necessary as to the magnitude of a right angle has been given under ANGLE: we propose here to point out the effects of the forced manner in which Euclid avoids the angle A O B.



It is sufficiently evident that nothing can lose its right to be considered as a magnitude by augmentation: so that the opening of A O and O B, which is double that of A O and O C, must really be a magnitude of the same kind as the angle A O C. Now the consequences of preferring A O C to A O B, as a fundamental angle of reference, are as follows:—

1. The introduction of the apparently very arbitrary axiom, that "all right angles are equal," instead of the more simple and natural one that "two straight lines which coincide in any two points coincide beyond those points." It is as evident as that "two straight lines cannot inclose a space," or "two straight lines which coincide in two points, coincide *between* those points," that the same also takes place *beyond* those points." A moment's examination will show that this axiom immediately gives as a consequence that the angle A O B in any one straight line is equal to the angle A'O'B' in any other; or as Euclid would express it, the doubles of all right angles are equal whence all right angles are equal. And it is one consequence of leaving the natural route, that Euclid himself has assumed both the more complicated axiom which he has expressed, and also the more simple one by which he might have avoided it: for he nowhere shows that if O A be made to coincide with O'A', then O B coincides with O'B'. Some of his editors have supplied the defect by making it a consequence of "all right angles are equal," that "no two lines can have a common segment:" that is, by making the cart draw the horse.

2. The necessity of appearing to prove a particular case of a proposition which is taken as self-evident in all other cases. Thus Euclid never proves that C O D and D O B are together equal to C O B; while he has to spend a proposition in proving that A O D and D O B are together equal to A O B.

3. The necessity of appearing to prove a particular case after the general case has been proved. Thus to bisect a given angle is the general proposition of which to draw a line perpendicular to a given line from a given point within it, is the particular case. The construction of the latter is precisely that of the former: but the two results have to be obtained in two distinct propositions: it would be right enough to make them cases of one proposition.

4. The habituation of the student to neglect the angles greater than two right angles, by his never meeting with one *as great*. Two lines which end at the same point make two openings, one greater and the other less than two right angles; except in the intermediate case when both are equal to two right angles. Now Euclid does not positively reject the angle greater than two right angles, nor does he say that of two lines which meet, the angle which they make shall be always taken to be that which is less than two right angles. Had he had such intention, one of his propositions would have been positively false, to wit, that in any segment of a circle, the angle at the centre is double of the angle of the circumference. Had such been his intention, he would have said, "in every segment *which contains an angle less than a right angle*, the angle at the centre is double of that at the circumference." It is true that his proposition is, "In a circle, the angle at the centre is double of the angle at the circumference *when they have the same circumference for a base:*" and some may think that the words in italics exclude (as in one sense they certainly do) the segment which has an angle greater than a right angle; since this angle, and its central angle, that, namely, which is less than two right angles, do not stand on the same circumference as a base. Let this be so, then we throw the difficulty on another proposition, the 27th. It is there shown that "in equal circles, the angles which stand upon equal circumferences are equal whether they stand at the centre or *at the circumference.*" If no mention of angles greater than two right angles be intended in the previous proposition, then the one before us is not completely proved, but only when the angle at the circumference is less than a right angle. At the same time there seems to be, in some of the subsequent propositions, proof of a desire to avoid the angle greater than two right angles, and to subdivide proofs into particular cases in order to avoid the difficulty.

But are we not in fact to assume, without particular inspection, from the general tone of the first six books, that the angle equal to or greater than two right angles was never really meant, and that all propositions are to be taken with such limitations as the above restriction would render necessary? Let those who think so, look at the last proposition of the sixth book, in which it is shown that in equal circles angles are to one another as their subtending arcs. Now the criterion of PROPORTION, as given by Euclid, requires that, in this proposition, any multiple, however great, of the angles may be taken. Now a multiple of an angle may not only be greater than two right angles, but greater than a thousand right angles; and every such multiple must not only be really included in the demonstration, but considered as a magnitude, and compared with other magnitudes of the same kind. It is impossible that the writer of the fifth book should have been unable to bear in mind that the establishment of proportion demands that every possible multiple of the quantities asserted to be proportional should be admitted and compared with every other: and thus it is certain that Euclid must have meant to consider angles not only greater than two right angles, but even greater than four, or any other number. Some commentators have supposed that Euclid meant to omit all pairs of right angles from such multiples, and all semicircumferences from the multiples of the arcs; but this would only be a use of the axiom, that if equals be taken from unequals, the remainders are unequal, which admits the greater of the quantities mentioned to be comparable magnitudes: and that Euclid does consider them as such, is all that is contended for.

RIGHT, PETITION OF. [PETITION OF RIGHT.]

RIGHTS, BILL OF. [BILL OF RIGHTS.]

RIGIDITY OF ROPES. In estimating the powers of machines, it is frequently necessary to take into consideration the effects arising from the rigidity or stiffness of the ropes which pass over the pulleys or the axles of the wheels; and, in order to understand how this condition affects the relation between the moving power and the resistance, let it be observed that when a stiff rope is bent over the upper part of a wheel or pulley in a vertical plane, for example, the weights or powers applied at its extremities may not be sufficient to draw the descending portions into the positions of two vertical lines. Now, if one of the parts of the rope should take such a direction that a vertical line drawn through the weight attached to that part, cuts the horizontal diameter of the wheel or pulley at a point between the centre and one extremity of the diameter, and if, at the same time, the other part should take such a direction that a vertical line drawn through the attached weight cuts the horizontal diameter at a point beyond the extremity of the latter, the distances of these vertical lines from the extremities of the diameter being represented by x and x' respectively, the corresponding weights by W and W', and the radius of the wheel by R, the conditions of equilibrium, instead of being $W = W'$, will be

$$W(R-x) = W'(R+x').$$

But, if W be the weight which by descending raises up the other, the value of x is generally so small that it may be disregarded; so that we have, in the case of equilibrium,

$$W R = W'(R+x'), \text{ or } (W-W')R = W'x',$$

$$\text{or again, } W - W' = \frac{W'x'}{R};$$

that is, in order to put the system in a state of equilibrium, the excess of W above W' should be equal to $\frac{W'x'}{R}$.

The formula given by Coulomb to express the force necessary for overcoming the rigidity of a rope, or the equivalent of $\frac{W'x'}{R}$, is

$$\frac{r^m}{R}(a + bW');$$

r being the semi-diameter of the rope, a the force arising from the warping or twisting of the rope, and b that which depends on the tension arising from the weight W; the values of m, a, and b may be determined by experiments made with cords of different diameters; and thus x' may be found. M. Coulomb ascertained that for slender string, $m = 1$, and that for stiff cordage the value of m varied from 1·5 to 2; also, from some experiments made with ropes consisting of 30 threads and 2¼ inches in circumference, he found that the weights requisite to overcome the rigidity, when the ropes passed over a pulley 4 inches diameter, and were strained by weights equal to 25 lbs., 125 lbs., and 425 lbs., were 5 lbs., 8¼ lbs., and 23 lbs. respectively.

Unfortunately ropes of equal dimensions differ much in rigidity, so that little dependence can be placed on the results of general formulæ in estimating its value. White ropes when wet are more stiff than those which are dry, and the rigidity of ropes is greatly increased by tarring them. In general, the weights necessary to overcome the resistance of tarred ropes is proportional to the number of the threads of which they are composed. General Morin has latterly revised the observations of Coulomb and of Navier on the subject of the rigidity of cordage, and has published the results of his inquiry in his 'Aide Mémoire de Mécanique Pratique,' and in his 'Leçons de Mécanique Pratique.' These essays have been translated and printed in the 'Engineer's, Architect's, and Contractor's Pocket-Book,' and from them it appears that Coulomb's rules, tables, and formulæ were prepared on a rather confined view of the case. Morin's own tables and formulæ are given in the translation thus quoted.

RING. [ANNULUS.]

RINGWORM is the term applied to many cutaneous eruptions, and more particularly to those on the head. It is not now possible to determine to which of these the name was first applied; but it is probable that the species of *Herpes* which appear in the form of rings were thus designated, especially that which nosologists call *Herpes circinatus*. This disease is still often called ringworm, when it appears upon the forehead or scalp; but the same name is still more generally applied to the different forms of *Porrigo*, especially *P. larvalis* and *P. scutulata*. The descriptions of the diseases thus confounded under this name will be found in the articles HERPES and PORRIGO.

RINGS, COLOURED. [UNDULATING THEORY.]

RINMAN'S GREEN. [COBALT.]

RIOT. A riot is a misdemeanor at common law; and is defined by Hawkins to be "a tumultuous disturbance of the peace by three persons or more, assembling together of their own authority, with an intent mutually to assist one another against any one who shall oppose them in the execution of some enterprise of a private nature, and afterwards executing the same in a violent and turbulent manner, to the terror of the people, whether the act intended were of itself lawful or unlawful." The assembling together therefore in a case where the law authorises parties to meet and use force in concert, as for the purpose of suppressing rebellion or opposing the king's enemies, or as part of the posse comitatus, will not constitute a riot. Neither will a sudden quarrel occurring among a number of persons who have met together at a fair, or on similar occasions, constitute a riot. But if on the occasion of a meeting, lawful in itself, some act of violence in disturbance of the peace is afterwards proposed, and executed in concert by those who are assembled, they will be guilty of a riot. The enterprise must be of a private nature, not necessarily relating to an individual, but still having in view some minor and special, and not a general public object. The object may be, for instance, to redress a grievance said to be suffered by some particular person, or to pull down inclosures on lands where the inhabitants claim a right of common. For if the enterprise be for the purpose of redressing grievances throughout the kingdom, or pulling down all inclosures, the offence is not riot, but amounts to a levying of war against the crown, and becomes high treason.

Violence, if not of actual force, yet in gesture or language, and of such a nature as to cause terror, is a necessary ingredient in the offence of riot. The lawfulness of the enterprise operates no further than as justifying a mitigation of the punishment. It does not in any way alter the legal character of the offence.

Two minor offences of rout and unlawful assembly, which are similar to riot, are generally treated of under that head.

A *rout* is where parties have commenced but not accomplished an enterprise, and in such a way that if the enterprise had been executed, they would have committed a riot.

It is an *unlawful assembly* when great numbers of people meet together with such circumstances of behaviour as to raise the fears of their fellow-subjects, and endanger the public peace. An assembly therefore of a man's friends to defend his person against violence threatened to him if he appear in a public place is unlawful, as such conduct tends to produce a breach of the peace. But an assembly in a man's own house to protect him while there, or to defend the possession of it, is not considered an unlawful assembly. At common law the sheriff and all peace officers are bound themselves to make every effort and to command all others to assist them to suppress a riot. It seems also that where the emergency is great and immediate, private persons on their own authority may act, and even use arms for the same purpose. On such occasions it has not been usual for the military to take any part except in the presence and under the direction of a civil authority. They are not however by law disqualified for any duty or relieved from any responsibility which under the same circumstances attaches to other classes of their fellow-subjects.

Various acts of parliament have been passed for the purpose of giving atuhority to magistrates and others in suppressing riots, and restraining, arresting, and punishing rioters. The most important is 1 Geo. I., st. ii. c. 5, commonly called the Riot Act, which provides that "if any persons to the number of twelve or more, being unlawfully, riotously, and tumultuously assembled together to the disturbance of the public peace, shall continue so assembled for the space of an hour after the magistrate has commanded them by proclamation to disperse, they shall be considered felons."

The form of proclamation is given in the Act, and is to be read with a loud voice and as near as possible to the rioters. Persons who do not disperse may be seized and apprehended by any magistrate or peace-officer or any private person who has been commanded by a magistrate or an officer to assist. In case of resistance, those who are attempting to disperse or apprehend the rioters will be justified in wounding or killing them. It is felony to oppose the reading of the proclamation; and if the reading should be prevented, those who do not disperse are still guilty of felony, if they know that the reading of the proclamation has been prevented.

A prosecution under this Act must be commenced within a year after the offence has been committed. By 7 & 8 Geo. IV., c. 30, s. 8, rioters who demolish or begin to demolish a church or a chapel, a dwelling-house, or any other of the various buildings or machinery mentioned in that Act, are to be considered felons, and by 7 & 8 Geo. IV. c. 31, provision is made for remedies against the hundred in such cases, if to the amount of 30*l.*; but if the damage does not amount to 30*l.*, before justices at a petty sessions.

The action must be commenced within three months after commission of the offence; and to entitle the party injured to bring it, he must, within seven days after the injury done, go before a magistrate and give on oath all the information relative to the matter which he possesses, and also be bound over to prosecute the offenders.

With respect to unlawful assemblies of a seditious character, see SEDITION; TREASON.

RISK. In the theory of PROBABILITIES the risk of loss or gain means such a fraction of the sum to be lost or gained as expresses the chance of losing or gaining it: thus an even chance of losing 40*l.* is considered as a positive loss of one-half of 40*l.*, or of 20*l.*; and 2 to 1 for gaining 60*l.* is counted as two-thirds of 60*l.*, or 40*l.* If both these risks were encountered at the same time, the whole transaction would be considered as a gain of 40*l.*—20*l.*, or 20*l.*, since this is the sum which would be netted by every such transaction in the long run, and one with another.

The following is the method of ascertaining the effect of the division of risks. Let there be an adventure in which the chance of success is p, and that of failure $1-p$. Let failure produce the loss of £ n and success the gain £ m: then $pm-(1-p)n$ is the result of every such transaction one with another. Let this last be called M; it is required to estimate the probability that in s transactions the average effect (gain or loss, according as M is positive or negative) shall lie between $\mathrm{M}+l$ and $\mathrm{M}-l$. Calculate the square root of s divided by $2p(1-p)$; multiply this square root by l, and divide the result by $m+n$. Take the table in MEAN (using it as in PROBABILITY, col. 774), let the last result be A, then the corresponding B is the probability required. [WAGER; WEIGHT OF OBSERVATIONS.]

RITUAL (from *ritus*, in the sense of *consuetudo*), the book which directs the rites and ceremonies to be observed in celebrating divine service in any particular church.

RIVER. In a legal sense rivers are divisible into fresh and salt-water rivers. Salt-water rivers are those rivers or parts of rivers in which the tide ebbs and flows. Rivers are also divisible into public or navigable rivers and private rivers.

The property in fresh-water rivers, whether public or private, is presumed to belong to the owners of the adjacent land; the owner on each side being entitled to the soil of the river and the right of fishing as far as the middle of the stream. But this presumption may be rebutted by evidence to the contrary. If a fresh-water river between the lands of two owners gains on one side by insensibly shifting its course, each owner continues to retain half the river, and the insensible addition by alluvium belongs to the land to which it attaches itself; unless the lands of the proprietors on each side has been marked out by other known boundaries, such as stakes, &c. in the river. (Bracton 'De acquirendo rerum dominio,' 'Dig.' 41, tit. 1, s. 7.) But if the course of the river is changed suddenly and sensibly, then the boundaries of the lands will be, as they were before, in the midst of the deserted channel of the river. Special custom may also alter this general presumption of law. Though fresh-water rivers are presumed to be the property of adjacent landowners, yet no such owner can set up a ferry and demand a toll unless by prescription or by charter from the king. In early times also the king by his prerogative might prevent all persons from fishing or fowling in any river until he had first taken his pleasure there. This was effected by directing a precept to the sheriff commanding him to cause all persons to abstain from approaching the banks. By Magna Charta this prerogative was restricted to such streams as it had been exercised upon in the time of Henry I. Subsequently the custom was to name the rivers in the precept to the sheriff; among these was the Avon, at least that part which flows through Worcestershire. Eventually the prerogative fell into disuse. In those rivers which are navigable, and in which the public have a common right to passage, the king is said to have "an interest in jurisdiction," and this is so not only in those parts of them which are the king's property, but also where they are come to be private property; such rivers are called "fluvii regales," "haut streames le roy," "royal rivers"; not as indicating the property of the king in the river, but because of their being dedicated to the public use, and all things of public safety and convenience being under his care and protection. Thus a common highway on land is called the king's highway, and navigable rivers are in like manner the king's highway by water. Many of the incidents belonging to a highway on land attach to such rivers. Accordingly any nuisances or obstructions upon them may be indicted even though the nuisances be in the private soil of any person; or the nuisances and obstructions may be abated by individuals without process of law. It must not however be inferred that all the incidents of a land highway attach to such rivers. Thus, if the highway of the river is obstructed, a passenger will not be justified, as he would be in the case of a land highway, in passing over the adjacent land. And though a river is a public navigable river, there is not therefore any right at common law for parties to use the banks of it as a towing-path.

If a river which is private in use as well as in property be made navigable by the owner, it does not therefore become a public river unless from some act it may be presumed that he has dedicated it to the public. The taking of toll is such an act. Callis says that the soil of the sea and of royal rivers belongs to the king. But the expression, if intended to apply to all parts of the rivers where the public have a right of passage, appears too comprehensive.

But there is no doubt that in some such rivers the property may be in the crown; as it was in the river Thames, the property in which, both as to the water and the soil, was conveyed by charter to the lord mayor and citizens of London. And in all rivers as far as the tide flows, the property of the soil is in the king, if no other claims it by prescription. In navigable rivers where the tide flows, the liberty of fishery is common and public to all persons. (Hale, 'De Jure Maris et Brachiorum ejusdem'; Callis, 'On Sewers.')

The property in the mere running water is in no one; but the proprietor of adjoining land is entitled to the reasonable use of it as it runs by his land. "And consequently no proprietor can have the right to use the water to the prejudice of any other proprietor. Without the consent of the other proprietors who may be affected by his operations, no proprietor can either diminish the quantity of water, which would otherwise descend to the proprietors below, or throw the water back upon the proprietors above. Every proprietor who claims a right either to throw the water back above, or to diminish the quantity of water which is to descend below, must, in order to maintain his claim, either prove an actual grant or license from the proprietors affected by his operations, or must prove an uninterrupted enjoyment of twenty years."

RIVER ENGINEERING. The laws of hydraulics which apply to the flow of water in rivers may be briefly expressed as follows:—If a uniform velocity be once established, in a channel of whatsoever section, the same quantity of water must pass through that section in the same periods of time; and it follows from this that the velocity of the current must be increased proportionately to the diminution of the area, if the same discharge take place. As the rate of flow in open channels depends entirely upon gravitation, it must increase with the inclination; and, in order to maintain an equable discharge, the other conditions of cross section must be made to agree with this inclination. In channels, however, of uniform inclination and section, the rate of flow rapidly attains uniformity; for the friction of the water upon the sides and the bottom of the beds soon counteracts the accelerating force of gravity. It also follows, from the effects of the friction upon the wet contour, that the velocities of the different films of the transverse section are never uniform; because those which are in contact with the sides are retarded in their rate of flow, and they, in their turn, act to retard the flow of the films immediately around themselves; the maximum velocity being on the surface and on the axis of the deep water—the minimum velocity on the bed. Du Buat by direct experiment found that the mean velocity of a stream, in an open channel, might be expressed by the formula $v = cV$; in which v represents the mean velocity; c, a coefficient varying between 0·76 and 0·891; and V the surface velocity. In practice it is usual to consider that, for surface velocities of from 8 inches to 5 feet per second, $v = \frac{4}{5}V$, or that $V = 1{\cdot}25\,v$; but in large rivers it appears that, as in the Seine, $v = 0{\cdot}62\,V$; and in the Neva it is, $v = 0{\cdot}75\,V$; the horizontal position of the line of the mean velocity seems to range between 0·88 and 0·92 of the depth considered as unity. Du Buat also found that the bottom velocity called $U = 2v - V$, in which v and V retained their previous signification; and from thence we have, when $V = 1{\cdot}25\,v$, $U = 0{\cdot}75\,v$; or $v = 1{\cdot}33\,U$. It is the bottom velocity which acts by its transporting powers on the materials of the bed of a river, and has the greatest effect upon the stability of its banks.

In a channel of uniform velocity and section, if we call the discharge Q, and the sectional area S, v retaining its signification of the mean velocity, we have $Q = Sv$, and from this $v = \frac{Q}{S}$. The inclination of the bed, I, will be found by De Prony's formula $I = \frac{P}{S}(av + bv^2)$, in which P = the wet contour, or the developed length of the wetted surface; S = the sectional area; and a and b, coefficients, which he (adopting throughout the dimensions in metres and their subdivisions) made respectively 0·0000444 and 0·000309. Eytelwein made these coefficients $a = 0{\cdot}000024$ and $b = 0{\cdot}000365$, but it appears that De Prony's values are the most correct for small channels, whilst those of Eytelwein are the most correct for large rivers. If again we call the quotient of the transverse section S by the wet contour P the *mean radius*, and represent it by R, we have $R = \frac{S}{P}$, and the formula of De Prony gives us $RI = 0{\cdot}0000444v + 0{\cdot}000309v^2$; from thence we obtain $v = \sqrt{0{\cdot}005163 + 3233{\cdot}428\,RI} - 0{\cdot}07185$ or $v = 56{\cdot}86\sqrt{RI} - 0{\cdot}072$. Playfair gives this formula, in English feet and inches, $v = \sqrt{0{\cdot}023751 + 32806{\cdot}6\,RI} - 0{\cdot}1541131$; and from it the value of v can be easily ascertained if I and R be known, or we are enabled to fix the rate of inclination I requisite to secure a velocity such as shall ensure that $v = \frac{Q}{S}$ when the other terms are known.

De Prony's formulæ, modified, if needs be, by Eytelwein's observations, will serve not only to calculate the discharge, and the other conditions of the flow of water in a regular uniform channel, but also to calculate the conditions of the flow of water in rivers, provided a length of about 500 yards can be found upon it, where the channel is of a tolerably uniform section, and the velocity is regular. A cross section of the stream will give S and P, from whence R will be derived; and I will be ascertained by actual levelling. When the cross section is not constant the average area of a number of cross sections will suffice for ordinary calculations, and the inclination may at any time be ascertained from v by actual observation, when it is not possible to level the line of the mid-stream. If the river should happen to be divided into two branches, with marked inequalities of bed and flow, it would be preferable to consider each of them separately. For rough approximate calculations the volume of a river may be likewise ascertained by the formula $Q = S\,(0{\cdot}08\,V)$ in which S signifies as before the sectional area, and V the surface velocity; but it is essential that every possible precaution should be taken to secure a correct value for V.

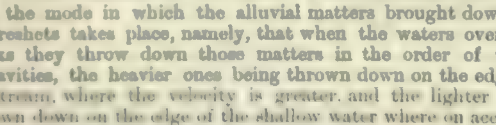
It must not be supposed that the transverse section of any flowing body of water is perfectly horizontal on its upper surface, because it will be found that immediately over the portion of the section where the greatest velocity prevails, the surface will be slightly raised above the level of the shallower portions of the stream. In small rivers it is not possible to distinguish this species of surelevation; but in larger ones it is at times strongly marked. A phenomenon of more importance to the stability of banks consists in the existence of a zone of still water, comparatively in close proximity to the shore in consequence of the greater resistance to the flow through the friction of the banks; and in this part of the stream may also be observed a series of small eddies produced by the impulsion of the current. The principal direction of these eddies appears to be directly opposed to that of the main stream; and moreover it will be found that when any obstacle is offered to the onward flow of the water, the latter will in the first place heap up against this object, and finally give rise to a distinctly marked counter current, technically known as a *back-water*. If the obstacle should extend across the whole stream, the upper surface of the water will assume a sensibly parabolic longitudinal section, the apex of which will be situated at a considerable distance up stream, and the axis upon the deep water-line. If the obstacle, however, should only be upon one bank, the back-water will not extend for any great distance; but it may frequently happen that the effect of the counter current would be so great as seriously to endanger the stability of the bank itself. The spurs, which are in many cases introduced for the purpose of defending the shores of rivers, when they extend far into the stream, produce this particular effect; and they may often be observed to give rise to a series of eddies, currents, and back-water, which wear away the shore at the points where they are joined to the land, on the upside especially. Another effect produced by a projection into the line of flow of a stream is that the portion of the current which does not go to form the back-water, is deflected from its course, and may perhaps be made to impinge in a dangerous manner on the opposite bank. At any rate the current at the foot of a spur into a main stream is sure to deepen the bed of the river at its foot, and to carry the channel towards the convex side of the bank; indeed this law holds universally, and in rivers it is always found that the deep water channel follows the convex side of the meanderings, and that the channel thus naturally tends to straighten itself by the more rapid abrasion which takes place against the projections. From these remarks it would follow that whenever it is desired to regularise the courses of rivers it is preferable to do so by means of longitudinal parallel walls, rather than by spurs; and that the direction of the new channel should be made as far as possible rectilineal, or at least with curves of very large radii. M. Defontaine observed on the Rhine that elbows of 8300 feet radius produced but small effects upon the bed, or banks, of that river, notwithstanding that they were composed of easily transported materials; and it may be inferred from this that a bend whose radius should be not less than twelve times the width of the maximum water line may be admitted in permanent works of this description. The above reasoning of course applies in the most exclusive manner to rivers whose flow is in only one direction; when the tidal action is brought to bear upon them, other conditions of regimen are developed to which attention will be called hereafter.

The nature of the materials of the bed a river may flow over will affect the chemical quality, and therefore the value, of its waters for such purposes as irrigation or water supply; and this, too, whether the materials taken up be so taken in solution, or merely in mechanical suspension. In WATER SUPPLY, attention will be called to the chemical portion of this inquiry; but at present it is advisable to dwell upon the merely mechanical effects produced, for the outlines of the beds of rivers depend mainly upon them. Now the longitudinal profile of a river almost always forms a species of parabolic curve, whose apex is in the high lands, and whose base is at the embouchure; so that the rate of flow is greater near the source than it is near the embouchure, the transporting and the erosive powers being also diminished in the same proportion. By the experiments of Du Buat we learn that the following materials will be carried forward by waters flowing with the velocities named in connection with them in the table:—

River mud, semi-fluid silt . .	Speed per second		0	feet	3	inches.
Brown pottery clay . . .	"	"	0	"	3¼	"
Common clay	"	"	0	"	6	"
Yellow sandy loam	"	"	0	"	8½	"
Common river sand . . .	"	"	1	"	0	"
Gravel, size of small seeds . .	"	"	0	"	4½	"
" peas . . .	"	"	0	"	7¼	"
" beans . . .	"	"	1	"	0½	"
Coarse ballast	"	"	2	"	0	"
Sea shingle, 1 inch diameter . .	"	"	2	"	2	"
Large shingle	"	"	3	"	0	"
Angular flints, size of hen's eggs .	"	"	3	"	3	"
Broken stones	"	"	4	"	0	"
Soft schistose rocks . . .	"	"	4	"	4	"
Rocks, with distinct stratification	"	"	6	"	0	"
Hard rocks	"	"	10	"	0	"

It thence follows that when the velocity of the river attains any of the above rates, it will be able to attack and remove by erosion the materials of its banks, which would remain in suspension at those velocities. In designing a system of river defences, however, attention must be paid exclusively to the *maximum*, not to the *average* velocity of the stream; because in flood time not only is the volume, but also the velocity, greater than at any other period, and the materials of which the banks are formed must be able to resist the transporting power of the floods. However, in consequence of their variable transporting power, rivers in their normal state flow over materials gradually decreasing in volume as they leave the steeper parts of their courses and approach their outfalls; and as those materials necessarily become at last very fine, especially in long flat plains, they offer little resistance to occasional floods, as may be observed in the deltas of such rivers as the Nile, Danube, Ganges, &c., which are composed of the fine mud brought down from the uplands, and in which the course of the stream continually shifts.

Some curious effects may be observed to take place with regard to the deposition of alluvial matters near the junction of streams draining areas of country situated under marked differences of thermometrical or hydrographical conditions; because the floods (or as they are technically called *the freshets*) frequently occur at distinctly different epochs, and thus, by reason of the freshet of one affluent ponding back the other a deposition of the matters in suspension in the retarded stream will be produced. It often happens that, under such circumstances, the accumulation of alluvial matters takes place in a manner to direct the local current against the banks in a direction essentially different from the main line of flow, the effect of which would be to divert the river from its original bed, to a greater or lesser extent, according to the resistance of the banks. There is another law with respect to the mode in which the alluvial matters brought down by floods or freshets takes place, namely, that when the waters overflow their banks they throw down those matters in the order of their specific gravities, the heavier ones being thrown down on the edge of the deep stream, where the velocity is greater, and the lighter ones being thrown down on the edge of the shallow water where on account of the friction the velocity is the least. The transverse section of a valley subject to freshets will be in fact something like the sketch here given. The banks will form slightly elevated ridges close to the water's edge, and the surface of the alluvial deposits will fall away gradually on either side; this condition may remain stable for some time, but there is always a danger from the tendency of the stream to create for itself a new bed in the lower level. On the Po, where the banks have been carefully maintained for centuries, the accumulation of the alluvial matters has taken place in the manner above sketched, but to such an extent as to create a real source of danger; for the banks of the river have been gradually so raised by the accumulation of alluvial matters, as to be in some cases as much as 40 feet above the extreme depression. [ALLUVIUM, in NAT. HIST. DIV.]



A few final general remarks with respect to non-tidal rivers may here be inserted, namely, that their volumes, even when they are of a comparatively stable character, vary within very wide limits. Thus the Rhone at Lyon, at times, flows with a volume of 7000 cubic feet per minute, at others with a volume of 203,000 cubic feet; the Rhine at Strasbourg varies between the limits of 9,500 and 164,000 cubic feet per minute; the Thames at Teddington between 5,400 and 15,000 cubic feet per minute. For the practical purposes of navigation, a current is considered to be slow when it does not exceed 1 foot 6 inches per second; a velocity of between 2 feet and 3 feet 6 inches per second is considered to be an average one; beyond the latter limit the velocity of the current is considered to be decidedly unfavourable to an upward navigation, and if the stream should flow at the rate of 6 or 7 feet per second, no boats can economically be made to work against it. When the rate of inclination of the bed of the river attains between 5 and 6 in 10,000, the velocity of the current becomes too great to allow of the navigation being carried on against it by the ordinary modes of traction; but by the use of steam tugs worked by high-pressure expansion engines, the Rhone has been navigated against the stream, even though its inclination has been on the *average* of its course from 7 to 8 in 10,000. Rivers which do not present a permanent depth of 1 foot 2 inches, with an available width of at least 14 feet, are not adapted to receive any kind of navigation, and they can only be rendered available for commerce by being canalized, or by being converted into what the continental engineers call floatable rivers. Streams of this kind occur in mountainous and woody districts, and are much used for the purpose of floating down rafts of timber, or such natural productions as are not likely to be injured by being occasionally submerged. When the width and depth of a river exceed respectively 18 feet and 18 inches, a barge navigation may be established, provided of course that the rate of flow be not unfavourable; and when the width and depth of the stream become respectively 60 feet and 8 feet, the river becomes navigable for sea-going vessels. The modes of propulsion to be adopted must depend upon local circumstances. In still water animal power is the most economical; steam is frequently used in deep water canals and river navigation; whilst sails, oars, and tides are frequently resorted to for this purpose in rivers adapted to their use.

In the lower parts of the courses of rivers discharging their waters into the ocean, and even to some extent in those discharging into tidal inland seas, a very marked interference takes place in the conditions of the currents, in consequence of the periodical tidal action. The tides themselves are produced by the periodical elevations and depressions of the level of the sea, caused by the combined action of the sun and moon, and under such circumstances they are naturally of greater amplitude on the shores of the larger bodies of water; on the Pacific, for instance, they are greater than they are upon the Atlantic; upon the latter, again, the tides are greater than upon the Baltic or the Mediterranean. The rising tide is called the *flood;* the falling tide, the *ebb;* and the returns of the tide take place twice in each consecutive interval comprised between the returns of the moon to the upper meridian. The mean length of this interval is 1·03505 day, so that the mean interval between two successive high waters is 0·517525 day, and the mean time of low water divides this interval again into two nearly equal portions. As in the case of all quantities susceptible of a maximum and a minimum, the increase or the diminution of the tides towards their limits is proportional to the squares of the time elapsed between the high and low tides. The height of the full tide on the sea-shore varies, normally, every day according to the phases of the moon; it is greatest at the syzigies, and least at the quadratures; but it is to be observed that in every place there is a species of retardation in the period of the high tide, as compared with the exact astronomical periods of the moon's changes, which is technically known by the name of the *vulgar establishment* of the place, and which depends upon laws to be noticed under TIDES. The rise of the high tides is usually proportional to the fall at low tides, but there is an irregularity between the heights of the two tides of the same day; the rise and fall at the syzigies is about double those of the quadratures, the former being called the *spring tides*, the latter the *neaps;* but it may be added, that the former are much increased when the moon is in perigee. An augmentation in the rise of the tide also takes place when the sun's declination is zero, or at the period of the equinoxes; and the greatest normal tide occurs when a new or full moon happens to occur near the equinox, when the moon is in perigee; and her action would be still further increased if her node should happen to coincide with the perigee. The other causes of the variations in the height of the tides may be neglected for the present, with the exception of those which are likely to affect their conditions in and upon rivers.

Thus, in cases where the tidal undulation is confined within a narrow gulf it becomes considerably increased in amplitude; and its reflection from the opposite shore may also increase that amplitude, especially in the recesses of such coasts. It is on this account that whilst at St. Helena in mid Atlantic, the rise is only 3 feet, and in the Northern Atlantic it never exceeds 10 or 12 feet, it is in the Bay of Mont St. Michel, 46 feet; in the Bay of Fundy, 50 feet; and in the Wye, at Chepstow, 60 feet. High winds, and especially the equinoctial gales, when they coincide with the spring tides may also give rise to great irregularities in the amplitude of the tidal range, and instances have even been recorded in which the tides of the quadratures have been raised by the effect of storms to a greater height than those of the syzygies. The disturbing effect of storms is, however, the greatest in seas with a small tidal range; as upon the French shores of the Mediterranean, where the normal rise of the tides is only from 6 to 12 inches, it is thus often increased to 3 feet. The most remarkable cause of disturbance in the range of the tides is, however, to be met with in the oceanic currents, and the manner in which they act varies in almost every case, producing some very singular interferences with the discharge of the upland waters, and with the deposition of the alluvial matters in the embouchures of rivers, whether the alluvions be brought from the sea, or from the interior of the country.

For instance, upon the shores of England we find that in consequence of the set of the tidal currents in the offing, the bars at the mouths of the rivers between Land's End and Portland, point from N.W. to S.E., as a rough general rule; between Portland and Selsea Bill, the in-shore tide runs in a direction opposite to that of the tide in the offing, and the bars of the rivers also point from N.E. to S.W. On the Atlantic shores of Ireland, the bars point rather S.E. to N.W.; they have the same direction on the western coasts of Scotland; whilst on the eastern coast of Scotland and of England, the bars upon the open coast point nearly from N.W. to S.E. In the mouth of the Thames two tidal currents meet, which have an origin separated by 12 hours' interval; so that not only are the day and night tides of that river equal in their amplitudes, but the alluvial matters transported by the tides are thrown down at the point where the velocities of the currents are destroyed, in banks which are constantly shifting. On the west coast of England again, there are in the rivers many instances of the double tide, arising from the reflection of the great tidal wave from a projection situated at a point beyond their embouchures, on the line of advance of that wave; and the conditions of the deposition of alluvial matters in these rivers are thus very different from the conditions ordinarily prevailing. Nor is this the only technical peculiarity connected with these rivers; because, in fact, the double tide is not so powerful as the normal tide for the purpose of carrying forward a barge navigation; but in another sense it is more favourable for the operations of commerce on a large scale, by reason of its retaining a great depth of water in docks and harbours, during the whole of the (so called) *slack-tide*. At Southampton, this slack tide lasts for nearly two hours; on the French coast the same phenomenon occurs at Hâvre, and in the Orne, during about 1½ hour in each tide. Great oceanic currents, wherever they exist, naturally produce analogous effects to these minor interferences with the progression of the tidal waves; but of course upon a much larger scale. A study of the history of the deltas of such rivers as the Nile, Ganges, Indus, Irriwaddy, Amazonas, Mississippi, &c., would be necessary for any one who desires to become acquainted with this important detail connected with hydraulic engineering. The actual records of the changes in the delta of the Rhine and of the Scheldt, would be of great interest and value also to the student; because they have been more closely and more scientifically observed than the changes which have recently taken place in other rivers of similar magnitude.

In the rivers exposed to the action of a complicated series of tides and currents, it is far more difficult to maintain a clear navigable channel than it is in rivers wherein the disturbing causes are more simple; and bar rivers, although extremely dangerous during stormy weather, are sometimes less inconvenient for the ordinary purposes of commerce than are those which, like the Thames, the Scheldt, or the Seine, are exposed to the injurious effects of the shifting sands thrown down at their embouchures. It is, moreover, to be observed that in the majority of cases the oceanic currents bring into the sheltered bays they meet with, a greater quantity of alluvial matters with the flood tides than the ebb tide can remove; and there is on this account a tendency in all such bays to silt up, a tendency which may distinctly be traced in the three rivers just mentioned. The maintenance of a navigable channel in these cases becomes a matter of difficulty, and it can only be effected temporarily by natural means, by securing the greatest possible scouring action of the tidal wave. The efforts of hydraulic engineers for this purpose should therefore be directed rather to concentrate the flow of the water in one well proportioned channel, than to secure merely a large volume of tidal water, without reference to the conditions of velocity it may be possible to impress upon the latter.. For this reason it is preferable, as a general rule, in designing works for the improvement of the navigable channels of rivers discharging their waters in tidal seas, to limit the width of the water-way in the lower portion, so as to drive the tidal wave as far inland as possible; and for the same reason every interference with the direct transmission of the tide is objectionable. Many illustrations of the truth of these propositions might be found on our own shores; but the success of the works executed for the improvement of the Clyde, Tyne, Seine, &c., must suffice to prove that the most important condition for the maintenance of a clear tidal navigation is, that the water should always possess a uniform velocity throughout its longitudinal and its transverse sections. In cases like the one which occurs at the mouth of the Tyne, where the passage through which the flood tide enters is contracted by the long bar extending from one shore nearly the whole width of the river; and where the flood, once admitted, can suddenly expand itself over a wide bay, it will be almost impossible to prevent the formation of alluvial deposits both from the sea and from the land; and if a second contraction of the water-way should take place abruptly above the inner bay, the peculiar phenomenon known by the name of the *eagre* or *bore* may be observed. The bore, in fact, is caused by the sudden influx, into a narrow channel, of a large volume of water flowing with considerable velocity, which rises in the form of a sudden wave, and constitutes a serious source of danger to the small craft navigating the rivers where it exists. On the Hoogley and on the Amazonas the bore sometimes rises almost literally like a wall of 12 feet in height; on the Severn and the Seine it is often 6 feet high, and advances inland at the rate of about 6 miles per hour; on the Trent the eagre often rises as much as 8 feet, at Gainsborough, and there are even rudiments of the bore to be detected in the Thames. The bore of the Seine has been diminished by the works lately executed for the regularisation of the bed of the river above its embouchure, in the bay of Hâvre. [BORE.]

The practical rules for the improvement of a river must evidently, from what has been said above, be susceptible of endless varieties, according to the nature of the stream, and the purposes to which it is intended to be applied. Even if no direct commercial benefit is anticipated from such operations, it must always be desirable that the flow of water should be kept as regular as possible, and the bed of the stream should be made to render the greatest amount of service as an outfall for the surface drainage. There are, however, few rivulets which might not be made to render service for irrigation purposes, and directly the flow of water becomes sufficient to allow the establishment of water-wheels, working occasionally or continuously, the streams become of great economical value. It is difficult to discover how the right of property in running waters has been established; and it is a matter of serious doubt even whether the existence of such rights be not in itself frequently a source of public inconvenience; but as this state of things has existed from time immemorial it must be dealt with in its actual form, if it were desired to improve any particular stream. The precise objects aimed at in such operations are mainly to retain the waters in their beds, and to regularise the conditions of the flow of water in the channels; to prevent inundations, in fact, and to keep the stream constantly in a state which should enable it to perform the services it is applied to.

As to the prevention of inundations, that object may at times be effected by establishing, artificially, a system of reservoirs in the upper parts of a river's course, which should perform the same function which the Swiss lakes perform for the rivers coming from the Alps, that is to say, should store the storm waters during the winter months for the purpose of distribution in the dry season. Works of this description have been executed in the East, and they have been recommended for France; they might be very advantageously introduced in our own colonies, and especially in South Africa and Australia. In RESERVOIRS the modes of executing this particular class of works has been alluded to; and the reader may be referred, for further information on the subject of their influence upon inundations, to Frisi's work upon 'Torrents,' to Valles, Savigny, Suzell, Hun, Ribbe, Babinet, &c., who have written at length on the inundations of France. For the present it may suffice to add, that when the rivers become of sufficient volume to cause dangerous inundations, there seems to be less danger when the banks of the river are dressed off at the height of the ordinary winter flood lines (so as to allow the waters when they exceed that level at once to flow over the country), than when the waters are confined within narrow banks raised to a considerable height above the surrounding lands. In some places on the banks of the Po, a river subject to violent floods, the banks are made of two descriptions: "in froldi," when they are raised to the necessary extreme height at once, and on the margins of the stream; and "in golene" when they are raised at a great distance from the margins, so as to interfere as little as may be with the spread of the waters. The former course is adopted when the valley of the river is narrow and the foundations are good; the latter, when the valley widens out, and there is any danger of the undermining of the banks. A double system of dykes, such as the one adopted in Piedmont, might perhaps save the dwellings upon the banks of the Rhine and of the Maas, from the periodical returns of their disastrous inundations; at any rate it would materially increase the security of the banks themselves when ice floats down in large quantities, as the piling up of the hummock ice is more injurious to the light earthen or fascined embankments of those rivers than even the floods themselves.

The embankments thrown up for the purpose of protecting the submersable districts on the side of a river must be made of a great thickness, and with every imaginable precaution to ensure their stability and their water tightness. The surface exposed to the wash of the current must be protected if the embankment should be composed of easily transportable materials, by stone pitching, planking, concrete, wattling, cribwork, or by fascines, tunnages, or clayonnages, in the manner practised by the German, French, and Dutch engineers. As a general rule the tops of these banks are made wide enough to carry a road; and it is essential to make provision for removing from the landward side the drainage waters which may there accumulate; it would be better to effect this operation by lifting the drainage waters over the bank instead of passing them under it. Local considerations must, however, regulate the choice of all these details, as well as those connected with the materials to be used in the formation of the bank itself.

For navigation purposes the improvement of small streams in thinly peopled, mountainous, and woody districts, is almost forcedly limited to converting them into floatable rivers; and this is often effected by throwing a set of dams across the rivers, so as to form as it were locks of still water, in which the timber can be made into floats, and moved towards the sluices formed in the dams, which are opened whenever there is a sufficient accumulation of water to float the timber to the next pond. The width of these sluices is usually made about 20 feet, and the fall varies between 3 and 4 feet; but as the sluice-gates are opened suddenly and the waters escape as it were with a flash, it is not necessary to make the fall great. There are some very good works of this description on the Yonne, above Auxerre; and the dimensions of the one at Régilbert may perhaps be added, as a model for our own colonial engineers. The passage and sluice are formed by carrying out walls from both banks, in a species of funnel shape, with its wider mouth towards the upstream, of 233 feet in width, and a length of about 210 feet from its commencement to the passage, which is 20 feet in width and 33 feet in length to the sluice. Beyond the sluice the wing walls open out for a distance of 20 feet, and at the end to the down stream they have an opening of 24 feet; a floor, for the purpose of obviating the inconvenience of the cataract produced by the flash of water, is continued beyond the wing walls; the water is ponded up to a height of 4 feet, and the sluice is opened, and in a fit state to pass a raft, within about eight minutes. Occasionally it is desirable to combine sluices of this description with locks, or, in fact, to combine a navigable and a floatable system. In these cases the lock should be placed in the still water, on the opposite side to the flashing sluice; the latter being itself near the head of the lock chamber, and the tail of the lock being placed at a sufficient distance from the end of the dam to obviate any danger from the back-water, or cataract of the sluice.

The most generally successful mode of improving rivers of small and irregular volume is, however, their conversion into still water, or canal navigations, by the construction of locks, waste weirs, and moveable dams. The positions which are the best fitted for the construction of the locks are upon the subsidiary channels formed by the islands in the mid stream of the river; and, unless some peculiar local circumstances should intervene, it is customary to form the dam and waste weir near the head of the smaller branch, and to place the lock at the lower end of the island; so as, in fact, to convert the smaller branch into the navigable channel, and to leave the wider branch as the storm or waste water passage, or *goit*, as it is technically called. The principles of construction of locks, &c., are of course the same in these cases as in canals [CANAL]; and perhaps this portion of the subject may be dismissed, by saying that the only special works required for river navigations are those by means of which sudden floods are allowed to pass; for especial care must be taken to guard against the formation of cataracts on the down side of the lock gates. The style of moveable dam used upon the upper Seine appears to be one of the most satisfactory of any yet tried, and it might advantageously be adopted on many of our colonial torrential rivers. Their mode of construction has been described in a special treatise, by their author, M. Poirée, but a brief account of them will be found in the 'Aide-Mémoire of Military Sciences,' article, River Navigation.

The position of the towing-path is, after all, one of the most important parts of the operations connected with the improvement of the navigation of an inland and non-tidal river; and it may be stated that this path should be placed, wherever it is possible so to do, by the side of the deepest water, and immediately upon the banks of the river. The theoretical conditions required for such paths are, that they should be exposed to as few impediments to the passage of the tow-ropes as may be, and that the direction of the haulage should not be too oblique. It is desirable to keep the paths under the wind, in order to avoid the action of the latter upon the boats; and when bridges are erected, to carry the paths under the land arches, in order to avoid the necessity for casting off the ropes. The width of the principal path should be about 12 or 13 feet; and if, in consequence of the existence of any rapid or current, it should be necessary to form a second path, so as to allow another rope to be thrown out to keep the boat's head well in the centre of the stream, the second path may be made only 6 feet 6 inches wide. The height of the towing-paths should be made such as to allow of their being overflowed directly the river rises to such a height, during floods, as to render the navigation dangerous; or perhaps a safe general rule would be, to keep the top of the path only 2 feet above the ordinary winter flood line. Great attention is required in the maintenance of the banks and of the roadway of the towing-path, especially if a rapid navigation be maintained; the banks in this case should be pitched, and the surface of the roadway macadamised. Secondary streams or small affluents should be bridged over, so as to avoid the necessity for casting off the tow-ropes on approaching them.

In rivers with light and easily moved beds, and which are subject to violent floods, the navigable channel will be found to run between numerous islands, and occasionally to shift from one to the other bank of the stream. In such cases it frequently becomes necessary to rectify the bed by forming a new channel, or to fix the current in its original direction by works which should confine it in one of its previous channels. This class of operations is one which requires consummate skill, for the nature of the foundations is such as to render it more than usually difficult to contend with the undermining action of the stream itself, and any injudicious diversion of the current will in all probability endanger the banks of the river for a great distance. The most simple rules of a general nature hitherto applied in settling the dimensions and directions of new channels may be stated as follows: it being always observed that local circumstances may modify their application in a very serious manner. Firstly, with regard to the conditions of flow in the channels, it is known that the velocities vary in the inverse ratio of the cube roots of the widths; and secondly, that the cubes of the depths are in the inverse ratio of the widths; in practice the capacity of the new channel should be made equal to that of the ancient one, but the capacity in question should be obtained, wherever it is possible, by increasing the depth at the expense of the width. All obstacles to the navigation, in the shape of trees, rocks, shallows, &c., should be removed; and the new channel should be connected with the old one by curves of considerable radius. The banks of the new channel on the side opposite to the towing-path should be made in such a manner as to allow the water to flow into the bye-wash as soon as the floods bring down an abnormal quantity of water; and it is very seldom, in ordinary river-barge navigations, that the crowns of the dams forming the bye-washes are raised more than two feet above the full summer level of the stream. Excellent examples of the mode of constructing these lateral banks are to be found in Smeaton's works on the Carron, Telford's on the Weaver, and D. Stevenson's on the Ribble, though in some of these cases the tidal action intervened; perhaps the best treatises to be consulted on this subject are, however, a 'Mémoire on the Rectification of the Bed of the Midouze,' in the 'Annales des Ponts et Chaussées,' 1831; a 'Mémoire on the Defence and Improvement of the Navigable Channel of the Rhine,' by M. Defontaine, in the same publication for 1833; in Sganzin's 'Cours de Construction;' and in Brook's, Calver's and D. Stevenson's treatises on River and Canal Engineering.

The treatises last mentioned are, it is to be observed, more particularly composed with reference to the engineering works required for the improvement of the tidal or of the salt-water portions of rivers; but it may be added that, in all cases, the results of experience show that the most certain mode of regularising and deepening the bed of a river is by the establishment of continuous longitudinal embankments. With respect to the tidal or marine parts of the streams, the only remarks to be made in addition to those previously applied in the course of this notice are, that so long as the rivers discharge into seas wherein the tidal action takes place without interference, the navigation may be improved, and the depth of the channel maintained in an efficient state simply by the construction of lateral embankments, diminishing gradually in width according to the quantity of water flowing inland. Any sudden widening or contraction of the channel is injurious; but nature will eventually remedy the former disadvantage, for alluvial matters will be thrown down in the species of bay thus formed, and all that will then be required will be to keep the main channel open, in the precise direction required, by works of comparatively easy execution. In rivers like the Thames and Medway, the Seine, Rhine, &c., where the flood tide is enabled, by the peculiar laws of the deep sea currents, to carry in more alluvial matters than the ebb can remove (and in discussing this question of the movement of alluvions in rivers, the difference in the specific gravities of salt and of fresh water must not be lost sight of), in such rivers there must always be a danger of the channels becoming gradually silted up. The proper course to be adopted in such cases is to combine an efficient system of dredging with a regularisation of the upper portions of the channel, so as to develope and to concentrate the scouring action of the tide and of the current to the utmost extent; but it must always be understood that rivers placed under the action of this peculiar set of laws can only be kept open by the exertion of great skill, energy, and enterprise. It is true that hitherto little inconvenience has been felt in the Thames; in the Medway, however, a gradual shoaling up of the tidal portion of the river has been observed; the mouths of the Rhine are successively being choked; the mouth of the Scheldt is becoming less and less adapted for large vessels; and the Seine has been shown to present this peculiar characteristic, namely, that even at Rouen the alluvial mud consists rather of materials brought in by the flood tides from the sea, than of materials brought down from the interior by the fresh water. It may also be added, that, as the height and volume of water in a tidal river depend far more on the quantity of the tidal stream than upon any supply from the interior, it is comparatively easy to calculate the height to which the water may under any circumstances rise; and, when this has been ascertained, the banks on either side should be carried above the highest water-line; where towing-paths are used in rivers of this description, they should, if possible, be formed on both sides. A tidal current of about two to three miles per hour is usually considered to be advantageous for the trade of a river; and it is to the extraordinary facilities offered by the tides of the Thames that we may attribute the singular form of barge used upon it. These barges are in fact little better than logs which float on the top of the tide, and they contrast strangely with the barges used on the Seine, Rhine, Rhône, &c., which are built in such a way as to offer the least possible resistance to the current they are obliged to encounter beyond the limits of the tidal action.

Much information on the subjects alluded to in this article is to be found (in addition to the works already named) in Robison's *Mechanical Philosophy*; in Ellet's *Mississippi and Ohio Rivers*; in the *Raccolta dei Autori Italiani chi trattono del moto del acque*; Weibeking's *Theoritische Practische Wasserbaukunst*: De Prony's *Nouvelle Architecture Hydraulique*; D'Aubisson's *Hydraulique*; General Baird Smith's *Reports*, and his works on Irrigation, &c., &c.

RIVER IMPROVEMENTS. [River Engineering.]

RIVERS are the flowing waters which bring to the sea, and sometimes to a lake, the waters which are collected within a certain portion of the earth's surface. The country which is thus drained by a river is called its *basin*, as the river runs in the lowest part of it, and the country rises on all sides with greater or less steepness, in the fashion of the sides of a basin. The margin of such a basin generally lies contiguous to the basin of another river, and thus constitutes the boundary-line of the two basins. From these margins the waters descend on both sides towards their respective basins, which are separated by them, and hence the whole line of these margins is called a *watershed*, properly the *water-parting*. [Watershed.]

The basins of rivers vary greatly in size. A *brook* is the name commonly given to rivers of the smallest description. When such a river rises near the sea or near a large river, into one of which it flows after a short course, it consequently drains a very small surface. If the waters should be increased by those of another brook, the name of brook is changed for that of *rivulet*. The basin of a rivulet is therefore more complicated than that of a brook. One or more brooks descend from the margin of the basin, and by uniting their waters with those of the rivulet, increase its volume. When several rivulets unite and so produce a considerable volume of running water, this watercourse takes the name of *river*. But all such rivers do not reach the sea, or even a lake; most of them join other rivers, and thus a large river is produced. This last mentioned large river is called the *principal river*, and those which increase its waters are called, with respect to it, *affluents* or *tributaries*, and sometimes *feeders* or *branches*. In Syria and Arabia and north eastern Africa, the *winter-brooks*, or small streams which flow only in the winter or the rainy season, are called *wadies*, a term frequently met with in the works of travellers in these countries.

The first waters of a river are generally derived from a spring, which breaks out at the foot of a declivity, or on the side of some hill or mountain; and sometimes from a swamp or a lake. This is called the *source* of a river. From this source the river descends through the lowest part of its basin until it terminates its course in the sea, a lake, or another river, and this termination is called the *mouth* of the river. The cavity in which the running water flows is called the *bed* of the river, and the solid land which bounds this bed is called its *banks*. The *head-streams* of a great river are those, proceeding from their sources, which by their union or confluence produce the first principal stream, with which another principal stream may be afterwards *confluent*, or which may receive tributaries.

Most large rivers have their origin in very elevated mountains, or on high table-lands, in descending from which a great difference with respect to the rapidity of their course, and the nature of the country through which they flow, is observed. Accordingly geographers divide the whole of the course of such rivers into three divisions, the *upper*, *middle*, and *lower* course.

The *upper* course of such a river lies within a mountain region, and its source is consequently at a great elevation above the sea. The waters run with greater or less velocity, according to the greater or less extent of the mountain region, and the greater or less rapidity with which the whole region declines towards the country to which the whole course of the river is directed. When the elevation of the mountain-region decreases with great rapidity, the current of the river is extremely rapid, and presents a quick succession of cataracts and rapids. The force of the current is so great that pieces of rock of considerable size, which are frequently detached from the overhanging masses, cannot resist it, and are carried down by the current, until they reach a point where the rapidity of the descent begins to diminish. The mountains which constitute the banks of the river often rise several thousand feet above it, and their bases are united by slopes forming an angle, over which the water runs on bare rocks, without the least covering of earth. Thus the river does not flow in a valley, but in a cleft or ravine, which cuts deep into the mountain masses. Sometimes there is space enough for a path between the river and the mountains, but in many places this space is only obtained by artificial means, as by cutting away a projecting portion of the rock, or by making a tunnel through it. Where either of these means cannot be applied, the path is continued over the bed of the river by a wooden bridge of greater or less extent, until a place is reached which offers sufficient space for a path on the sides of the rocks. The course of the river is generally in a straight line, but sometimes it makes short and abrupt bends which form acute angles. In the last-mentioned case it is, almost without exception, observed that the mountains which inclose the river have on one side a projection, and on the other a recession, which correspond so exactly that if it were possible to unite the two mountains, the projecting would exactly fit into the receding part. This peculiarity in the formation of the ravines of mountain streams was observed by the Spaniards in the Andes of South America, who called them *quebradas*, or broken; by this term tacitly assuming that the phenomenon had been caused by a violent disruption of the mountains. This description of mountain-streams and their ravines applies particularly to those of the western Alps along their southern declivity, to those rivers which constitute the upper branches of the rivers Doria and Sesia, to the valleys of Anzasca and Vedro on the southern side of the great road of the Simplon, and to the still larger valley of Aosta, through which the road leads from Switzerland to Italy over the mountain-pass of the St. Bernard. The military road of the Romans was made through the Val d'Aosta; but in these parts it was only practicable for beasts of burden. Such deep ravines not only occur between the gigantic elevations of a high range, but likewise in the elevated table-lands. According to Dr. Beke, the rivers of Abyssinia, nearly all affluents of the Nile, or of its great tributaries, in the early part of their course, flow over the level surface of the table-land, being little more than muddy brooks, nearly without water in the dry season, but overflowing their banks so as almost entirely to inundate the plain country during the rains. They escape from the plateau by precipitous falls of 80 or 100 feet or more, into fissures in the rocky surface, at first only a few yards in breadth, but gradually opening to the extent of several miles, down which the stream hurries in a succession of falls and rapids, so as to descend several thousand feet in the course of a few miles. In these deep-cut valleys, the rivers thus soon reach a depression of 3000 or 4000 feet below the general level of the table-land. The larger valleys are of considerable width; that of the Abai, or Nile of Bruce, the upper course of the Bahr-el-Azrek, or Blue River [Nile, in Geog. Div.], for example, is at least twenty-five miles between the extreme points where it breaks away from the table-land on either side. "And as the country is wild and irregular," remarks Dr. Beke, "it is easy for a traveller, who has not taken a comprehensive view of the entire region, and who finds himself shut up in such a valley with a mass of broken country surrounding him, to believe that in ascending from the river he is crossing a mountain chain; whereas, in reality, he has merely reached the continuation of the table-land which he had left on the opposite side of the river." The great rivers of India present corresponding phenomena to those of the East African table-land, but on a more immense scale. [Plains.] Humboldt observes that the plain of Quito, which is nearly 10,000 feet above the sea, is intersected by ravines, which in some places sink so deep that their bottoms are hardly more than 2000 feet above the sea-level; and he adds that some of them are so narrow as not to contain the smallest cultivable space. Similar ravines intersect the table-lands of Guatemala and Anahuac, where they are called *cañadas*, a term, however, which does not imply the existence of rivers in them or relate to that circumstance, but merely to the abrupt descent of land.

When the mountain-region through which the upper course of a river lies descends with less rapidity, and consequently occupies a much greater extent of country, the mountain-streams, as well as their banks, present very different features. Both the streams and the banks show that the descent of the whole mass is not by a regular slope, but is formed by an alternation of plains and declivities; in ascending such a mountain-stream, it is found that in certain places the rocky masses approach so near to the banks, as to leave hardly room enough for the river, and in these narrows the current is extremely swift, and generally a contineal rapid, interrupted by falls of moderate height. These narrows however rarely extend more than a few miles. Above them the mountains recede to some distance from both sides of the river; and thus a basin is formed, in the middle of which the river flows with a comparatively slow current, not over bare rocks, but over a gravelly bed, and between low banks of earth. The bottom of the basin is level, or descends with a gentle slope, and may be cultivated or used as pasture-ground. In some of the rivers which descend from the central and eastern Alps, this alternation of narrow passes and basins occurs several times. Thus the Reuss, along which the great road runs which leads over the mountain-pass of St. Gothard, rushes with incredible velocity through the ravine of the Hospendal, and falls 1800 feet before it reaches the basin of the valley of Ursern, which is nearly eight miles long and more than half a mile wide, and in which it runs with a gentle course. At the northern extremity of the valley of Ursern the river enters the second narrow at the Urnerloch. This narrow, which extends about three miles to Geshinen, is extremely contracted, and within these limits the river descends 1074 feet, forming a succession of small cataracts. Below this is the basin of the Krachenthal, which is not so wide as that of Ursern, and about six miles long. The course of the river within this basin is rapid, but there are no cataracts. From this valley the river escapes by the third narrow, which is about four miles long, and also very contracted; it terminates at the village of Am-Stäg, where the Reuss enters the valley of Uri, in which it flows until it mingles its waters with those of the lake of Uri (Urner-see), as the southern part of the Vierwaldstädter-see is named. The same conformation is observed in the southern declivity of the Alps, where the river Ticino descends from the mountain-pass of St. Gothard. This river runs in a ravine from the Hospendal to Airolo, in which it descends about 2880 feet. It then enters the upper valley of Leventina, which is about seven miles long and half a mile wide, and in which the river is rapid, but has no cataracts. It issues from this valley by a narrow about two miles long, between Il Dazio and Faido, where a series of beautiful waterfalls occur, and the ravine is so narrow that an artificial road has been cut on the adjacent mountain called the Platifer. At Faido the Ticino enters the middle valley of Leventina, in which it flows with great rapidity to Giornico, a distance of about fifteen miles, but without forming any falls. The valley is less than half a mile wide, and often interrupted by rocks. Above Giornico the river enters a short narrow, at the outlet from which it forms cataracts, and then reaches the wide valley called the Lower Valley of Leventina, in which it flows with a comparatively gentle course to Lago Maggiore. The greater number of the rivers which originate in the Alps and Pyrenees are of this latter description. The basins which occur in these river-valleys may at some remote period have been filled with water, and this may have been drained off by the rivers forming an outlet for the waters by the narrows which now connect their basins with one another

A remarkable peculiarity of most of the rivers joining the Nile, dependent of course on the structure of the country through which they flow, is that they have a circular, or rather a spiral course, so that after having described a curve of greater or less extent, round the isolated mountain masses which break the uniformity of the table-land of Abyssinia, they return upon themselves at a comparatively short distance from their sources. As instances of this may be mentioned the Mareb, or Khor-el-Gash, the Bellegas, the Abai, the Gibbe, the Godjeb.

In some places the elevated mountain-ridges border immediately on low plains. In such cases the rivers cannot be said to have a middle course; for as soon as they reach the plain their character is changed, and the rapid torrent is converted into a gentle stream. Thus the Marañon, after issuing from the Pongo de Manseriche, and entering the great plain, flows slowly through the alluvial level; and the Ganges, after leaving the Himalaya Mountains, at Hurdwar, flows with great bends through the immense plains of India. [HINDUSTAN, in GEOG. DIV.] All the rivers which descend from the southern declivity of the Alps to the plain which the river Po traverses are of the same description. In most cases, however, the mountain-regions are not in immediate contact with the plains, but are separated from them by hilly tracts, and that portion of the course of a river which lies through such a hilly region is called the *middle* course. The rocky masses rarely approach the bed of a river which has a middle course, but retire to some distance from them, so as to form between the higher grounds a wide valley, which the inundations of the river have covered with a thick layer of alluvial soil. It is remarkable that the highest ground of these valleys occurs, without exception, on the very banks of the rivers, and that the land slopes from them towards the base of the higher grounds. Accordingly the inundations generally cover the lower tracts, which are at some distance from the river, to the depth of several feet, while the banks are still above the surface of the water. The slopes of the higher grounds, which may be considered as the outer banks of the river, because they fix a limit to its inundations, are generally gradual, and covered with vegetation. The current of the river itself is gentle. This change, when compared with that of the mountain stream, is partly due to the more gentle descent of the hilly region, and partly to the form of its course. The bed of the river rarely lies in a straight line, but continually forms bends, which are not acute angles, as in the case of the mountain-streams, but have only a small curvature, so that the river runs through the valley in a serpentine course. This circumstance renders the course of the river much longer than it would be if it flowed in a straight line, and consequently diminishes the fall and the rapidity of the current.

It is observed that rivers form numerous small islands and sand-banks a short distance below the place where they issue from the mountain region. Thus the Rhine, between Basel and Kehl, opposite Strasburg, and the Amazonas, below the Pongo de Manseriche as far east as the mouth of the Yapura, and the Mississippi, between the mouth of the St. Peter river and that of the Missouri, form islands and sand-banks. This is easily to be accounted for, by observing that the river, on issuing from the mountains, retains a large quantity of earthy matter in suspension, which subsides when the current decreases in rapidity. This sediment forms islets and sand-banks. Though it rarely happens, as already observed, that the rocky masses approach close to the banks in the middle course of a river, yet this generally occurs several times, and at such places the river usually forms rapids and whirlpools. A ledge of rocks traverses the bed of the river in some places. Such ledges occur in the Danube at Passau, near Neuburg above Vienna, near Presburg in Hungary above Pesth, and at Orshova, or Orsova, on the boundary line between Austria and Turkey. On the Rhine they occur only between Mainz and Bonn, where the river is traversed by three ledges, at Bingen, at St. Goar, and near Andernach respectively. Such ledges are found in nearly all the large rivers of Europe. The elevations by which they are produced are sometimes connected with ranges of hills.

Ledges of this description occur in many of the Atlantic rivers of the United States, as the Potomac, the James River, and others; and they mark with precision the passage of the rivers from the undulating or hilly region to the low plains along the coast. There are of course rapids where these ledges occur.

The *lower* course of rivers usually lies through a plain. In general there are no hills which constitute the outer margin of its course, and consequently there is no bottom or valley through which it runs. The banks are very little raised above the surface of the waters, and the level ground extends to a greater distance. The current is slow, the fall being very small. Thus it was observed by La Condamine, that the Amazonas from the narrow at Obydos to its mouth, a distance of 700 miles, does not fall quite 12 feet, or little more than 0·2 of an inch per mile. It can hardly be conceived that a river with so small a fall could propel its waters, and as the current of the Amazonas is considerable, it can only be accounted for by supposing that the enormous volume of water which the river brings down, drives on by its pressure that which is before it until it reaches the sea. [AMAZONAS, in GEOG. DIV.] The surface of the Elbe at Hamburg, about 70 miles from the North Sea, is not more than 6 feet above the sea, and the fall per mile very little exceeds an inch. The surface of the plain through which a river runs generally consists of an alluvium, which the river has deposited during the inundations. The matter of which this alluvium consists is soft and loosely bound together, and consequently the current, slow as it is, has power enough to remove a portion of the banks from one side, and to deposit the detached matter on the other. Thus great changes are produced in the courses of rivers in the lapse of time. Major Rennell surveyed a large portion of the lower course of the Ganges, and his maps were very exact at the time. He also observed the changes which the river had produced in its bed. About fifty years afterwards the course of the Ganges was again surveyed, for the purpose of establishing a steam navigation, and it was found that the course of the river hardly in any place agreed with the maps of Rennell. The most remarkable circumstance however is, that a river frequently divides into a number of arms, each of which runs to the sea, though some branches re-unite and again detach themselves from one another. Thus the Danube reaches the sea by seven arms, as the Nile formerly did, according to the ancient accounts, though there are now only five arms in the Nile. Our best maps represent the number of the mouths of the Ganges as amounting to ten at least. This division of a river into several arms is easily understood when the soft nature of the alluvium is considered: and if we suppose that the river in its operation of changing its bed, finds in its way a piece of rock or other matter harder than the alluvial soil, by setting against such an obstacle the current is divided, and flows on both sides of it: the following inundation removes still more of the alluvium, and thus, in course of time, a new arm is formed.

The country which is enclosed by the arms of a river is called its *delta*, from the form of the Greek letter Δ, which the delta of the Nile, that which was best known to the ancients, greatly resembles: but the term is generally appropriate, as most river deltas have that form. To the base of the triangle, however, the deposit of matter brought down by the river adds a curved projection seaward, rendering the entire form of what is called the delta that of the sector of a circle. It is a common conjecture that the space which is now occupied by the delta of a river was once a part of the sea, which was filled up by the débris and earthy matter brought down by the river from the mountainous and hilly country through which its upper and middle course lie. This supposition is strongly supported by the nature of the soil, which evidently consists of matter brought down by rivers, and not of such as the sea leaves behind when, from any cause, it retires. (On this subject see Captain Spratt's 'Investigation of the Delta of the Nile,' as referred to in the article QUICKSANDS.) It may be added, that this operation of rivers goes on during the inundations, for after the waters have subsided the surface of a delta is found to be covered with a very thin layer of mud, which soon becomes dry earth. The deltas of rivers which are annually swollen by rains, which is the case between the tropics, are generally much more extensive than those which are formed by rivers whose inundations are only produced by the melting of snow.

There is a river of first-rate magnitude which has no delta, though it seems to possess all those qualities which are supposed to be requisite to the formation of such an alluvial tract: the St. Lawrence in North America reaches the sea by a kind of bay, which extends upward of 300 miles, and gradually increases in width from three to above one hundred miles. One would suppose that the form of this bay would render it subject to be easily filled up by the earthy matter brought down by a river whose course exceeds 1800 miles; and yet we do not find that an alluvium of any extent has been formed along the banks of this wide æstuary, except on the right bank below Quebec. This single instance might throw some doubt on the opinion that deltas are formed by rivers in the way above mentioned, if the peculiar nature of the St. Lawrence did not suggest an explanation of this deviation from the common course of things, which rather confirms than refutes the established principle. The St. Lawrence is the only large river which traverses a great number of lakes. Even after having left the five great Canadian lakes, it passes through those of St. Francis, St. Louis, and St. Peter. In each of these lakes the current ceases, and it is only perceptible where the river again issues from the lake. All the earthy matter therefore which the river collects and keeps suspended in its course from one lake to the other is deposited in these lakes. Thus this large river brings no débris and earthy matter, or very little, to its wide æstuary, which cannot therefore be changed into a delta by the accumulation of such matter.

Most large rivers, as already observed, admit of this division of their course into three parts, an upper, middle, and lower course; but the exceptions are far from being rare. It sometimes happens that the characteristic features by which the middle course is distinguished, occur in the upper course. This takes place when a river originates on an elevated table-land, and traverses a considerable part of it. Thus the Indus, the Sutlej (an affluent of the Indus), and the Sampoo, rise on the elevated table-land of Tibet, and drain a portion of it: in this part of their course they resemble the middle course of the Rhine or Danube. But where they leave the plain and enter the mountain-region of the Himalaya, they resemble the mountain-streams of the Alps, except as to the volume of water. When the Indus and the Sutlej have descended into the plains of the Punjab, they assume the character of the lower Rhine and lower Danube. The Sampoo, after leaving the mountain-region, traverses a hilly tract of great extent, the valley of Asam, before it enters the alluvial plain of Bengal. There are other rivers, in which only the characteristic features of the middle and lower course can be recognised: the number of such is considerable, and some of them are of the first magnitude. Thus the Volga and Mississippi, neither of which rises in a mountain-region, but in a hilly tract, in the greater part of their course present the characteristics of the middle course of the Rhine and Danube, but towards their mouths they traverse a large plain. The number of rivers whose whole course lies through a hilly or undulating country is still greater, as is the case with nearly all the rivers of England and Southern Scotland. There are also rivers which in their whole course traverse a mountain region, but they are all small; such are some of the rivers in North Scotland and in Sweden, and nearly all the rivers of Norway, and those on the west coast of South America.

The number of rivers which do not reach the ocean is not great, if we except those which fall into the Caspian Sea and into the lake of Aral. The other rivers without an outlet always terminate their course in a lake. It was formerly supposed that the water of some of them was absorbed by a dry soil, and that they were lost in the sand; and this opinion still prevails as to some rivers which descend from Mount Atlas southward to the Sahara. But the point remains doubtful. Among other rivers which have no communication with the sea, some few traverse elevated table-lands, consisting of plains surrounded by continuous mountain-ranges, through which the waters cannot find an outlet, and consequently collect in the lower part of the plains, and form lakes large enough to part with all their surplus water by evaporation. Such rivers occur in the valley of Tenochtitlan in Mexico. The most remarkable is the Desaguadero, in the valley of Titicaca in Bolivia, which runs about 300 miles, and is lost in a lake or in swamps. The Hyarkan or Yerkan, in Chinese Turkestan, is still larger, but its character is imperfectly known. Another kind of such lakes occurs in the plains of Mexico and of South America, and almost exclusively in those parts which have no rain or very little. On the table-land of Mexico the greater number of rivers between 24° and 30° N. lat. terminate in lakes; and in the states which compose the Argentine Republic, rivers of this kind are numerous between 28° and 34° S. lat., west of 64° W. long. As very little rain falls in some of these countries and in others none at all, the rivers are supplied with water by the rains which fall at certain seasons on the mountains in which they originate, and by the springs which exist there. But as the supply of water is very moderate, it does not give force sufficient to the currents to carry them through those extensive tracts which separate them from the sea. It is remarkable that some of these rivers and all the lakes in which they terminate, are salt in South America; and it is probable that this is also the case with most of those on the Mexican isthmus.

Most rivers overflow the low countries which are adjacent to their banks, either at regular seasons of the year or occasionally. This takes place when the supply of water is greater than the bed of the river can contain. In this respect rivers may be divided into three classes: the first comprehends the rivers whose inundations are produced by the melting of snow and ice; the second comprehends those which are annually swollen by regular rains; and the third those which only occasionally cause inundations.

All large rivers that drain countries of which the mean winter temperature is below 30°, are annually subject to great risings when the snow and ice melt. In such countries snow falls for several months, and as only a small part of it is dissolved, it accumulates to a great amount. As soon as the frost ceases, the snow begins to melt, and runs off by the smaller rivers, which suddenly swell and carry an unusual supply of water to the principal river, whose volume being thus increased to three or four times its ordinary magnitude, overflows the adjacent low country. These inundations, though they generally improve the soil, are very injurious to agriculture, by destroying the growing corn, and covering extensive tracts with sand, gravel, and other coarse earthy matter. In some rivers these inundations last only from two to four weeks; in others two or three months; and in some even five or six months. Where the inundations are long, they are less violent, and cause less damage than when they are short; in the latter case the whole mass of water suddenly deluges the country, while in the former the water rises slowly. This difference in the inundations of rivers is mainly to be attributed to the direction in which they flow. Let us take a river like the Mississippi, which flows from north to south through 17° or 18° of latitude. In winter the basin is covered with snow, and if the whole were melted in a few days, it would produce such a volume of water as would probably cover nearly half the basin. But the melting of the snow is gradual. Whilst the temperature in the northern districts is below the freezing-point, the spring has already made considerable progress in the southern districts, the snow which has there fallen has been dissolved, and the water thus produced has had the requisite time to run off and reach the sea. Thus with the progress of the sun towards the northern tropic, the line of the melting snow proceeds northward, and thus the supply of water runs off gradually, until the snow of the most northern region is dissolved. More than two months elapse between the melting of the snow in the northern region and the commencement of the melting in the lower part of the river. The inundations of the Mississippi therefore are not extensive, if the great length of that river and of its affluents be considered, but they last from three to four months. A considerable part of the delta of that river is indeed under water for six months, but this must be ascribed to the tract of elevated ground which extends not far from the sea between the Atchafalaya and the La Fourche, and prevents the enormous mass of water which collects in the lowlands near the first-mentioned branch from running off sooner. When a river situated in the northern hemisphere flows from south to north, the melting of the snow of course commences near the upper branches of the river, and proceeds northward. In this case the volume of water which collects at a certain period in the lower course, where the lowlands are generally most extensive, is much greater, and the inundations are much more extensive and attended with more mischief. But still they cannot be compared with inundations of those rivers which run from east to west or from west to east. In countries which are drained by such rivers, the whole mass of snow is dissolved in a few days, especially when a thaw is accompanied by rain, and all the waters thus produced pass through the principal channel in the course of a week or two. In such rivers the volume of water during the inundations is three or four times larger than it is in the middle of the summer or the beginning of autumn, and the inundations spread to a great distance, and frequently cause great loss of property, and sometimes also of life, especially when the winter has been unusually long and the falls of snow very heavy. [NIEMEN, in GEOG. DIV.] But the river St. Lawrence forms an exception here also. As its general course is from west to east, one would suppose that a large extent of country within its basin would be annually subject to inundation, but this does not appear to be the case in any part of its course. If any portion of it is swollen by the melting of the snow within the basin, the river soon enters one of the lakes through which its course lies, and thus the addition of a comparatively small volume is not sufficient to raise the surface of the lake to any large amount. Thus the same cause which prevents its filling up the wide æstuary, prevents the river from overflowing the adjacent country. A diurnal rise and fall characterises the rivers of Switzerland and those of the western Himalaya, where a powerful sun melts the glaciers by day, and the head-streams are frozen by night.

Rivers whose inundations are produced by regular rains have the greater part of their course either within the tropics or at least between 30° N. lat. and 30° S. lat. It is a known fact, that in those regions heavy rain falls daily from three to six months in the year. These heavy rains commence when the sun in its progress from one tropic to the other approaches the zenith of a country, and they continue till it has passed a certain distance from it. In the beginning of the wet season, as this part of the year is called in those countries, the rains are sometimes so heavy that in the course of a day the level country is covered with water a foot deep. The rivers of course soon begin to increase in their volume of water, and after some time they rise to the level of the banks, and begin to run over. These inundations generally last from two to four months. They are more regular than those which are produced by the melting of the snow, and in general do not exceed a certain height. The rural economy of those countries in which they take place is founded on the knowledge of this periodical event, and on the certainty that the inundations will fertilise the fields by depositing on them a fine mud, which enriches the soil more than the best manure artificially collected and applied. The supply of fertilising matter may not be due in an equal ratio to all the head-streams or all the tributaries of a river. In the important case of the Nile, according to M. Linant, an eminent scientific traveller and geographer, it is by the Atbara, its first great tributary, that most of the black-earth and slime is brought down which manures the lands in Egypt; from which it has received also the designation of Bahr-el-Aswad, or the Black River. Whenever the inundations do not rise to the usual height, which is sometimes the case, a great part of the country which is not covered with water yields little or nothing, and the consequence is dearth and famine. When, on the other hand, the inundations rise higher than usual, they are also injurious to rural economy, by reaching those tracts which are set apart for the cultivation of plants, which cannot bear so much moisture as the districts that are regularly flooded. Thus, in 1831, the river Menam in Siam rose to an extraordinary height: the inundations reached the large orchards which for many miles in extent cover the more elevated tracts along the banks, and afford subsistence to a numerous population. Several kinds of fruit-trees were almost destroyed, and for some years the mangusteens and durians were scarce.

The Indus [HINDUSTAN, in GEOG. DIV.] belongs to both of these classes of rivers, or rather to all three. The elevation of its waters is owing to the periodical melting of the snow and the subsequent rains, and it is subject also to enormous occasional inundations. In the year 1841, according to Major Cunningham, in his work on Ladak, the mass of water accumulated, and which caused the inundation of the lands bordering the lower part of its course, was estimated at 20,000,000,000 cubic feet, equal to a volume 100 feet deep, 380 feet wide, and 100 *miles* long. A similar inundation, though probably of inferior magnitude, took place in August, 1858, when, at Attock, the water rose 50 feet in seven hours and a half, and attained 90 feet during the day. Its affluent, the Cabul river, *flowed upwards* for ten hours. Valuable investigations of the mechanical philosophy of these phenomena, and of the relations between the velocity of a river-stream and that of the tide—or other waves to which it may be subject, by Mr. J. Obbard and Archdeacon J. H. Pratt, will be found in the 'Journal of the Asiatic Society of Bengal,' N. S., vol. xxix. (1860, No. iii.), p. 263–282. The latter subject has important relations with that of the ascent of the tide up a river, noticed below.

All the rivers between the tropics which are swollen by periodical rains lie only in one hemisphere, the northern or the southern. In the countries through which they flow the waters are low and the ground dry during part of the year, so as to admit of easy cultivation, and at another season the fields are fertilised by the inundations. The Nile and the Amazonas are alone exceptions. Though the course of the latter river is in the southern hemisphere, its affluents extend far to the north and south, into both hemispheres, and probably three-fourths of the tropical rains which descend upon South America find their way to that large river. To this circumstance are owing its immense volume of water and its great depth. The Amazonas, properly speaking, is never at its lowest level, in the sense in which that term is applied to other rivers. When the northern rivers cease to bring down the supply which is owing to the periodical rains, the southern begin to bring their contributions. This fact seems sufficiently to explain the immense tracts of alluvial soil which extend along the river to a great distance, but the same circumstance also keeps the soil in a state of continual moisture, and makes it a perpetual swamp. Accordingly we find that the banks of that river, which admits of a more extensive navigation than any other river in the world, remain nearly destitute of agricultural settlements, and are still in the possession of savage tribes. In the northern portion of the upper course of the Nile, that river appears to be almost stagnant except during the rains, and to consist in the dry season of a series of swamps and lakes, rather than to form a continuous stream.

The rivers which drain the countries between 30° N. latitude and those in which the mean temperature of the winter season does not rise above 30°, are subject to occasional inundations. But these overflowings occur only in those rivers whose upper course lies within mountain ranges which are covered with snow for a considerable part of the year. In such cases, while the snow covers the more elevated portion of the mountain-ranges, a sudden change in the weather, which produces a warm wind, brings great volumes of vapours, which, falling in abundant rain, soon dissolve the snow, and the mountain-streams pour down their waters with increased volume and velocity. As soon as the waters reach a level tract, it is inundated. As these inundations often take place unexpectedly, they cause great damage. Thus we find that some valleys in the Ozark Mountains, in the United States of North America, are almost uninhabitable, owing to the sudden inundations to which the rivers of that mountain-region are subject. Many rivers however never inundate the adjacent country, unless a heavy gale of wind should blow directly up the river, and drive the sea into it with great force. Such inundations are very sudden, and sometimes also extensive, but they are of short duration. [CLIMATE: RAIN.]

An important subject in the history of rivers, relating to the distribution of temperature within certain areas of the earth's surface and the immediately incumbent atmosphere, and their equalisation in others, and which bears also on the connection of rivers with the welfare of organic nature and the human race, is the variation of their temperature in different parts of their course, both at the same and at different seasons. This depends, proximately, on the temperature of their affluents, and may even give information of the physical state of the countries in which they rise, when these are otherwise unknown. Dr. Joseph D. Hooker, in his 'Himalayan Journals' (vol. ii., p. 60), has given some interesting facts on this point, as presented by the rivers which rise in the Sikkim Himalaya. The Teesta, a tributary of the Megna, or Brahmaputra, is always cool in summer (where its bed is below 2000 feet in absolute elevation), its temperature being 20° below that of the air; whereas, in mid-winter, when there is less cloud and the snows are not melting, it is only a few degrees colder than the air. At Bhoomsong, of which the elevation is 1500 feet, the mean temperature of the Teesta, in that season, was 51°, and that of the air 52°·3; at that elevation the temperature of the water rarely exceeds 60° at midsummer. Between the altitudes of 4000 feet and 300 (the plains of India) its mean temperature varies about 10° between January and July; at 6000 feet it varies from 55° to 43° during the same period; and at 10,000 feet it freezes at the edges in winter, and rises to 50° in July. In June, in descending from 12,000 to 1000 feet, Dr. Hooker found that its temperature did not rise 10°, while that of the air rose 30° or 40°. The temperature of the northern feeders of this river, in some parts of their course, actually rises with the increasing elevation. Thus, the Zemu, during the traveller's stay at its junction with the Thlonok (which has its source in the north-east snowy flank of Kinchinjunga, one of the three or four highest mountains in the world), was at 46°, or 6° warmer than the latter; at 1100 feet higher it was 48°, and at 1100 feet higher still it was 49°. "These observations," Dr. Hooker adds, "were repeated in different weeks, and several times on the same day, both in ascending and descending, and always with the same result: they told, as certainly as if I had followed the river to its source, that it rose in a drier and comparatively sunny climate, and flowed among little snowed mountains." Another explorer of nature, Mr. Alfred R. Wallace, has recorded ('Travels on the Amazon and Rio Negro,' p. 431) some facts apparently of the same description, not, however, observed by himself, and which he professes his inability to account for. In the month of May some very cold days are said to occur annually on the Upper Amazon and Rio Negro, sometimes so severe that the inhabitants suffer much, and the fishes in the rivers even die of the cold; though five or ten degrees of diminution of temperature, Mr. Wallace remarks, is as much as ever takes place. We conceive the depression of temperature of the local atmosphere affecting the inhabitants to be occasioned by the air brought down in contact with the cooled water of the rivers, the temperature of which must be still lower, and that the cause is the annual melting of the snows about the sources of some of their head-streams.

In adverting to the advantages which a country derives from its rivers, we must first observe that the water is extensively used for the purposes of domestic economy. It is much purer than that of wells; for river water in general contains much less saline matter than spring-water; it has also earthy particles in suspension, which may easily be separated by filtration, and which are deposited as a sediment when the water is left to stand for a short time. The water of wells generally contains a small quantity of some mineral salts in solution. The water of rivers is used, and is nearly equal to rain water, for all domestic purposes. The upper courses of rivers are generally inhabited by a small number of species of fish, and the whole amount is not great. But towards their mouths the number both of species and individuals increases. The importance of a river fishery may be estimated when we consider the quantity of salmon which is taken in the rivers of Britain, or of the beluga and sturgeon which is caught in the neighbourhood of Astrakhan. Many rivers, which are not adapted to the purposes of navigation, are converted into powerful instruments for assisting the industry of a country by the moving-power which they supply for mills and other heavy machinery. The advantage of such a natural moving-power primarily determines the seat of manufactures, as was the case in South Lancashire, where this advantage is combined with abundance of coal. The Atlantic States of North America are generally provided with abundance of streams, a circumstance which favours the establishment of manufactures.

The greatest advantages however which a country derives from its rivers are the facilities which they supply for conveying the produce of agriculture and of manufacturing industry to distant parts at a moderate expense. In this respect the rivers may be compared to the arteries and veins of the human body, which diffuse life and strength through all parts. Navigable rivers vivify, maintain, and excite the efforts of human industry. In many countries, where roads are neglected, it is estimated that the transport of goods by land is four times as expensive as that by means of navigable rivers, and thus many heavy and bulky commodities could not be brought to market but for the cheap conveyance of rivers. In considering the capacity of a river for navigation, two circumstances mainly require notice—how far seafaring vessels may ascend, and how far the river is navigable for river boats.

Seafaring vessels can ascend many rivers as far as the tides extend. Indeed some rivers, as the Amazonas, may be navigated by large vessels to a much greater distance than the tide ascends, but in others the waters become shallow long before the limit of tide-water is reached. Still high tides facilitate the navigation of rivers by large vessels, not only by producing a current contrary to that of the river, but also by temporarily increasing the depth of water so that vessels can pass over shallows and sandbanks, which at low tides are nearly or quite dry. This is frequently the case in rivers where the tides rise more than 12 feet. The tides in rivers are not of equal duration, as is the case in most parts of the sea; but the ebb tides frequently last twice as long as the flowing tides. At Rotterdam the tides flow for about 4 hours and 5 minutes, but the ebb lasts 7 hours and 55 minutes. The Meerwede at Dordrecht flows against the current of the river for 3 hours and 51 minutes, and with it 8 hours and 9 minutes. This difference is easily explained, when the force of the river current is taken into account. The same circumstance explains the difference in the velocity of the ebbing and flowing tide. Between the North Sea and

Hamburg, the flowing tide takes 5 minutes to run up a mile, but the ebb tide performs the same distance in less than 4 minutes. But it is difficult to explain the well-established fact that the tides advance much farther into a river than might be expected. When the tide at the mouth of a river rises 4 feet, we might suppose that it would advance only to such a point in the river, where the surface is 4 feet above the sea, but it has been ascertained that it advances further. It seems that the volume of water which is carried up by the tide is pushed onwards by the mass behind it, and carried to a greater distance than the inclination of the river bed would seem to allow. It has also been observed, that during the flowing of the tide the surface of the water in the river presents a somewhat convex form, the water along the banks being a little lower than in the middle of the river, and that during the ebb the contrary takes place. The flowing tide raises the water from below, and thus sooner affects the main body of the river, where it has more room to operate, than the water near the margin. In accordance with this explanation it is observed that the flowing tide is perceptible in the middle, while it is still ebbing along the banks, and that vessels which are at anchor near the banks are turned round before the water on the surface of the river near the banks begins to flow upward.

In a few rivers the tide ascends to a great distance from the sea. In the Amazonas it is perceptible in the Narrow of Pauxis near Obydes, a distance of nearly 500 miles from the mouth of the river, measured along its course. If we suppose that the tide in this river advances at the rate at which it runs in the Elbe between the North Sea and Hamburg,—namely, nearly a mile in five minutes,—the tide can only reach the Narrow of Pauxis in 42 hours, or in a space of time during which the direction of the tides has changed seven times at its mouth. It is therefore evident that the current of the Amazonas between the sea and the Narrow of Pauxis must, at the same time, in three or four different parts of its course, follow the impulse given to it by the tide, and run against the stream. We are of opinion, however, that the tide in the Amazonas advances more slowly than in the Elbe, owing to the stronger current of the Amazonas, and that the number of high tides in the Amazonas, between the two above-mentioned points, will probably be found to be five or six. The tide rushes into some rivers with great impetuosity, and produces what is called a *bore*. [BORE; WAVE.]

Human ingenuity, even in the lowest state of civilisation, has perceived the use of rivers as means of conveyance. Perhaps all rivers which have water enough to carry the smallest boats of any shape or form are navigated, except where the nature of the current opposes insuperable obstacles. These obstacles consist of *cataracts* or of *rapids*. When the river descends from a rock which rises several feet perpendicularly, it rushes down in a broken sheet of water, and is said to form a cataract. When the water descends with great velocity over an inclined plane of rock, it is said to form a rapid. A cataract may be descended when it is only a few feet high. Rapids may be ascended and descended in most cases with great labour and some danger, when they are not very long, and the bed of the river is free from projecting rocks, which however is rarely the case. The ascent of rapids is effected either by poling or by dragging the boats over the dangerous place by means of long ropes. Sometimes ropes are also used in the descent, as in the Rhine at Laufenburg in Switzerland. But generally either the whole cargo or a part of it must be taken out of the boat, and carried a certain distance by land. Such a tract, over which the goods must be carried, is called a *portage*. At long and dangerous rapids the boats themselves must be carried or dragged over the portages.

River boats differ greatly in shape and construction, being always adapted to the nature of each river. Most rivers contain numerous shoals, on which the water is very shallow, and accordingly flat-bottomed boats are used, like the coal-barges in London. Keel boats can only be used where the river has a depth of a few feet, and is free from shoals and sand-banks. When a river is shallow and rapid, but of considerable width, rafts are substituted for boats. Rafts generally consist of trees fastened together with ropes or the flexible branches of trees, or, in warm countries, by creeping plants; goods are placed upon the raft. When these rafts, with their cargoes, have arrived at their place of destination, the raft itself is sold, either as timber or as firewood, according to its dimensions and quality, and the crews return by land. When a river is too full of cataracts and rapids to allow either boats or rafts to descend, it may still be used for floating down timber or firewood. The trunks of trees, after being deprived of their branches, are thrown singly into the current, and towards the mouth chains are laid across the river, above which the trunks collect, and whence they are carried to their destination. This is frequently done in the rivers of the southern districts of Norway.

Rivers which traverse a mountain-region in some parts of their course are either not navigable in this part or only in some places. Thus the Amazonas and Ganges, where they respectively flow within the ranges of the Andes and Himalaya Mountains, are not navigable; but the Rhine and the Danube are navigable even within the mountains, in some parts for a considerable distance. The most extensive system of internal navigation is presented by those rivers which have a long course, and whose sources are situated at a comparatively small elevation above the sea. The Volga is navigable in the whole length of its course, and the Mississippi up to the Falls of St. Anthony, a distance of about 1800 miles, measured along the river. Both these rivers, as already observed, have the greater part of their course between hills of small elevation, and they do not traverse a mountain-region.

The rivers of England supply the means of an extensive system of inland navigation—a circumstance partly due to their small fall, their sources being only a few hundred feet higher than their mouths, and partly to the abundant supply of water from rain, mists, and springs. Accordingly, if two rivulets unite, they generally form a small navigable river, and such as are not navigable become useful as feeders to canals. The navigation of most of the rivers of England has been much improved by artificial means.

The Thames is navigable for large sea-vessels to London Bridge, a distance of 45 miles from the Nore, though the whole course of the river, measured along its windings, hardly exceeds 200 miles. No river in the world, perhaps the Amazonas excepted, is navigable for vessels of such dimensions for one-fourth of its course. This circumstance is not due solely to the height of the tides, which is about 19 feet at London Bridge, but mainly to the fact that there are no sand-banks at its mouth which prevent the access of large vessels. The river probably brings down sufficient earthy matter to form a bar but owing to the direction of the tide, which is kept off from the mouth of the river by the projecting coast of Kent between the two Forelands, and there being consequently nothing to oppose the current of the river at its mouth, the earthy matter is carried farther from the coast, and deposited in deep water.

The advantages hitherto enumerated are common to rivers in all parts of the globe; but there are some countries in which the value of rivers is much increased by the use which is made of the water for irrigation. This occurs in those countries in which it either does not rain at all, or in which rain occurs only at a certain period of the year, and even then only for two or three months. The first class of such countries—for instance, the western coast of South America, between 5° and 28° S. lat., would be uninhabitable but for the rivers which descend from the western declivity of the Andes, and in their course to the sea have furrowed the surface with deep depressions or valleys, in which agriculture is carried on with success as far as the water of the river can be dispersed over the level part of the valleys by small canals. In those warm climates where the rains occur periodically, though only in two or three months of the year, the fields would certainly produce a crop, even without irrigation; but for more than half the year the soil would produce nothing for want of water. By using the water of the rivers for irrigating their lands, the inhabitants of those countries are enabled to get two, and in many cases three, crops annually. Even in the southern countries of Europe, where rain is very scarce in summer, and not sufficient to maintain vegetation, whilst the heat is excessive, irrigation is practised, and two crops of Indian corn are thus annually obtained, or one crop of wheat and a green crop.

In those countries in which the temperature for three or four months is under the freezing-point, the rivers during that time are covered with ice, and in this state they afford to the inhabitants, in some degree, the advantages which other countries derive from railways. Travelling and the transport of goods on the smooth ice of the rivers are much less expensive, and are performed in a shorter time than in summer in the ordinary way. This is the case on some of the rivers of New Brunswick and Lower Canada.

It has been observed, that the outer borders of river-basins are the most elevated parts which occur in some given places between their respective beds, though it is not always the case that the water-parting is formed by mountain-ridges. Owing to such a disposition of the surface, the waters which are collected on or near the borders run to one or the other of the two rivers. Up to the commencement of this century it was thought improbable, if not impossible, that two different river systems or basins could be united by a natural water communication; but it is now ascertained that a low tract of country or a deep depression of the surface may occur, by which a portion of the water of a river, after being diverted from its own channel, may join a river which otherwise is not connected with that river from which the water branches off. The instances in which this occurs are very few, and we shall therefore enumerate those whose existence is beyond all doubt. The river Arno, in Tuscany, in that part where it runs between the high ridges of the Apennines and approaches the town of Arezzo, sends an arm southwards through a narrow valley, under the name of Chiana, which falls into the Chiare, an affluent of the Tiber. The Chiana had been filled with sand, but its course has been re-established by artificial means. Another case occurs in the kingdom of Hanover, a few miles east of the town of Osnabrück, where the river Haase divides into two branches, of which one, running west to Osnabrück, preserves its name, and, after a course of many miles, joins the Ems; the other, running east under the name of Elz, falls, after a short course, into the Werre, an affluent of the Weser. In Sweden, two large rivers fall into the northern extremity of the Gulf of Bothnia—the Tornea Elf and the Calix Elf. About 100 miles from the sea, the last-mentioned river sends off an arm to the south-east, which, after a course of about twelve or fifteen miles, falls into the Tornea Elf: this arm is called Tarenda Elf. In these cases the rivers thus united by a natural water communication flow in the same direction, or nearly so. But in South America, two large rivers, the Orinoco and the Amazonas, are united in this way in a part of their extensive courses, where the Orinoco runs west and the Amazonas east. The branch of the Orinoco by which this natural water communication is effected is called the Cassiquiare. [Orinoco, in Geog. Div.] This phenomenon is otherwise described as the *bifurcation* of a river high up its course, of which the Mareb, one of the tributaries of the Nile, already mentioned, affords another example.

It is a kind of established rule, that the whole course of a river should bear the same name, and that this name should be continued to that branch or head-stream whose sources are farthest from the mouth. But practice is frequently at variance with this rule, and in a manner establishes another. The inhabitants of a country preserve the name of that river which does not undergo any deflection of its course. At the confluence of the Mississippi and the Missouri, the latter is the larger river, and has had a course of above 1000 miles more than the former, but it does not deflect the course of the Mississippi by its junction, and the name of the last-mentioned river is preserved. The same occurs in South America as to the Amazonas and Madeira, where we find that the last-mentioned river changes the direction of its course to meet the Amazonas, whose name is preserved. In Europe, the Rhine is joined by the Aar in Switzerland, above Laufenburg. The Aar is the larger river, and brings down a greater volume of water; but the Rhine, where it is joined by it, continues its westerly course, and its name is preserved. There are also two rules for determining which of the various head-streams of a river is entitled to be regarded as its upper course, and consequently to bear the name borne by the united stream lower down: the one rule is at the same time theoretical and natural; the other is practical or conventional. By the former, the greater length and size, and the general direction of the valley or basin of the river, are the main considerations. By the latter, it is the first acquaintance which the inhabitants or discoverers of the valley of the main stream may make with one of its branches (or the converse) that causes the name of the former to be extended to the latter.

The extent of a few river basins is here given in round numbers, but they must only be considered as rough approximations:—

Rivers.	Square Miles.
Thames	6,500
Atbara, the fertilising tributary of the Nile	60,000
Rhine	89,000
Euphrates, including the Tigris	108,000
Brahmaputra	270,000
Danube	312,500
Indus	410,000
Ganges	443,000
Volga	653,000
Nile	707,500
Yan-tse-kiang	742,000
Mississippi	1,100,000
Plata	1,200,000
Oby	2,000,000
Amazonas	2,330,000

According to Humboldt the area of drainage of the Amazonas measures 3,000,000 of square miles; but in this he, in all probability, includes that of the Tocantins [Brazil, in Geog. Div.] which Mr. Wallace, correctly in our opinion, regards as a distinct river.

RIVETING, considered in its simplest form, is nothing more than the hammering of an iron bolt through a hole punched in two iron plates; but in the vast engineering operations of the present day, where rivets are used, not merely by the thousand, but by the million, the rapid and exact management of the operation become important matters. The Britannia tubular bridge over the Menai was the first of these great examples of rivet-fastened plates; the *Great Eastern* steamship was a second; and the Victoria railway bridge over the St. Lawrence, at Montreal, is a third. The rivets themselves may be simply pieces cut off from iron rods, and heated in a forge to a state fit for hammering; but under Nail Manufacture will be found a notice of certain machines which are equally suited for making nails, rivets, nuts, and spikes.

At a meeting of the Institute of Mechanical Engineers, in 1857, Mr. Harvey made the following observations on rivets and riveting:—"In the manufacture of steam-boilers, the operation of riveting is mostly effected by hand-labour; and in order to bring the heads of the rivets to a proper form and finish, much of the hammering takes place when the rivet has approached to a nearly cold state. The tendency of this is, to destroy, to a certain extent, the fibrous character of the rivet. The case of a rivet-head, starting off under the operation of proving the boiler, although seldom occurring, has revealed the fact that a crystalline character must be more or less assumed by the iron in all rivets worked in the usual manner; and hence, besides ariving at economy by the use of steam for riveting, it is very desirable that the rivets should be finished in as short a time as possible, and without that succession of blows by which the fibrous character of iron is always more or less injured." In hand-riveting, it may be added, the head is made conical by the shape and action of the riveting hammer; whereas in steam-riveting the head becomes convex, which is better. Nevertheless, steam-riveting machines, though many have been invented, have not hitherto come much into use. Some are found to be too complex, and likely to get out of order. Some require a pressure of steam of 50 lbs. on the square inch, with either a separate boiler or a large steam-cylinder, which renders them too costly. Some have a defect arising from the peculiar mode in which they act; a cam, moving through a fixed distance, and acting through a combination of levers, with a fixed distance for the travel of the riveting die, is unable to adapt itself to irregularities in the lengths of rivets which may occur in general work, and which *must* occur when rivets go sometimes through two, and at other times through three thicknesses of plates. Messrs. Whitelaw and Harvey have endeavoured to surmount some of these difficulties in a riveting-machine of recent introduction. The steam-cylinder is 15 inches in diameter by 24 inches stroke. A system of levers and eccentrics carry a shearer, a punch, and a die; for the machine is intended to perform all three operations of cutting iron plates, punching holes in them, and then driving rivets into the holes. The machine is not wholly self-acting; it is momentarily stopped by hand after every stroke. The effective action of steam is upwards; the downward movement is the effect of the weight of the moveable parts of the apparatus. Between the piston and the bottom of the cylinder a portion of the exhausted steam is retained as a cushion, to bring the piston softly to rest. Steam of 20lb. to the inch has pressure enough for this machine. It has power to punch a hole three-quarters of an inch diameter through a cold iron plate three-quarters of an inch thick, and to effect the cutting and the riveting for the same plate. In riveting, the action upon the rivet-head is a *pressure*, not a blow; this pressure becomes more and more intense as the process advances, until just before the head of the rivet is finally shaped, it amounts to something like 30 tons.

In riveting, whether by hand or by machine, it is necessary to furnish a pressure against one end of the rivet to assist the action at the other. In the hand method, one man holds a hammer forcibly against one end of the rivet in the hole, while another strikes the other end. In the machine method, the action is like the pressure of a die and counterdie.

RIVULIN. A mucilaginous matter found in a species of fresh-water plant, the *Rivula tubulosa*.

ROAD. Under this head it is proposed to embrace road-making, with a brief sketch of the history of roads, referring for more detailed statistical information to the Geographical Division of this work, and to Way and Turnpike Trusts for an explanation of the laws respecting the formation and maintenance of the highways in this country.

The importance attached to roads by the great nations of antiquity is abundantly testified by historians, though, except in the case of the Roman roads, there are few remains existing. The Carthaginians are said to have been the inventors of paved roads, which were much used by the Romans, who were distinguished by the vast extent and solid construction of their highways, of which several thousand miles were made in Italy alone, while every country which was brought under their sway was more or less intersected by these channels of communication. Though formed mainly to facilitate military movements, the Roman roads were productive of the greatest civil benefits. Being made by a power whose resources were almost unlimited, these military roads were usually laid out in straight lines from one station to another, with little regard to natural obstacles, which were frequently passed by means of very extensive works, as excavations, bridges, and in some instances, tunnels of considerable length. The solidity of their construction was fully equal to the boldness of their design; a fact proved by the existence of many that have borne the traffic of near two thousand years without material injury. The Roman engineers were very particular in securing a firm bottom, which was done when necessary by ramming the ground with small stones, fragments of brick, &c. On this carefully prepared foundation a pavement of large stones was firmly set in cement, the stones being occasionally squared, but more commonly of irregular shapes, though always accurately fitted to each other. For this purpose many varieties of stone were used, but the preference seems to have been given to basalt, where it could be had, it being used in many situations in which other suitable materials might have been procured with less labour and expense. Where large blocks could not be conveniently obtained, small stones of hard quality were sometimes cemented together with lime, forming a kind of concrete, of which masses extending to a depth of several feet are still in existence. The Roman roads were generally raised above the ordinary surface of the ground, and frequently had two carriage tracks separated by a raised footpath in the centre.

In some parts of the continent of Europe, especially in Italy, the Roman system of road-making has been imitated, particularly in city pavements; but in Britain the attempts to follow the Roman model appear to have been very limited, and road-making has been very imperfectly practised till within the last half century. Many of the existing highways were originally mere paths or tracks from place to place, their course having been determined more by accidental circumstances than by a due attention to the properties of a good road. Thus deviations were made from the direct course in order to cross rivers at fordable points, and the road was conducted over a hill in preference to a more level course round its base, to take advantage of natural drainage. As improvements have been introduced in the systems of construction and repair, the direction and levels have been frequently left unaltered, to avoid the temporary inconvenience and expense attending a deviation from the established course. The scanty information we possess as to the state of the roads in early times indicates that it was very bad; and after the introduction of turnpikes, and even down to the commencement of the present century, the greater part of the roads were, owing to injudicious modes of construction and repair, in a state very unfit for traffic.

The inefficiency of the system of maintenance by parish and statute labour was proved before the passing of the first Turnpike Act in 1653; yet the necessity of improvement, and the obvious justice of maintaining roads by the produce of tolls, did not lead to the extensive adoption of the turnpike system for about a century after that time.

During the last sixty years the attention of government has been repeatedly directed to the importance of this class of public works, and the Highland and Holyhead roads, formed by Telford and others, did much in improving and extending the science of road-making. The Highland roads alluded to were made under the commission of 1803, and originated in the military roads formed in consequence of the rebellions of 1715 and 1745, which had been found very beneficial to the districts to which they afforded the means of access. The roads made and improved under the management of the Highland road Commissioners extend to more than 900 miles, the whole being in a mountainous district, but so well laid out that their inclinations are always moderate. The works executed in the formation of these roads are very extensive, and comprise upwards of 1100 bridges. The Holyhead road improvements were commenced in 1815, and in these Telford and his able assistants had the opportunity of carrying into effect, under a government commission, a plan of road making suitable to a great traffic, on principles generally considered to be nearly perfect. The principles on which these important works were executed are very fully detailed by the late Lord Congleton, then Sir Henry Parnell, in his valuable 'Treatise on Roads,' to which work the writer of this article is indebted for much of the following information. The name of McAdam must not be passed over without notice in this place, as his exertions have done much towards attracting public attention to the improvement of roads, even where his peculiar principles have not been acted upon.

Though much remains to be accomplished, and the philosophy of road-making is yet very imperfectly understood by a large proportion of those to whom the care of the highways is committed, it is impossible to compare the past and present state of roads without feeling grateful for their improvement, and observing in how great a degree that improvement has benefited the agricultural, commercial, and moral interests of the community.

Designing a Line of Road; Earth-works, &c.—Though formerly little attended to, the design of the plan of a line of road is a subject which requires extensive knowledge and mature deliberation. It is often advisable to survey several different lines, in order to the selection of the one which, on careful comparison, appears to have the preponderance of desirable qualities. To be theoretically perfect, a road should combine the qualities of straightness and level, and its surface should be smooth and hard; and the best road, practically, will be that which makes the best compromise between unavoidable deviations from this theoretical perfection. It may be observed, however, that although some writers speak of the absolute perfection of each of these qualities as essential to the idea of a good road, it may be questioned whether it be desirable of any, excepting of the first. Of these qualifications the first two belong to the design or laying out of the line, and the last two to the execution of the road and the materials made use of.

The qualities of straightness and level, or the *line of direction* and *line of draught*, should be very carefully adjusted to each other. Some remarks on this subject will be found in the article Railway, which apply equally to the laying out of common roads, though the proportionate retardation due to a given ascent is very different, owing to the great comparative resistance of a common road. Among the circumstances that may authorise a deviation from the straight line, are the power of obtaining suitable materials for the road, avoiding valuable property or difficult ground, and including towns or villages in the route.

It seems to be a prevailing opinion with modern engineers, that the line of direction has not generally been made as subordinate as it should be to the line of draught; and it will be well to remember, in laying out a new road, that while the effect of gravity must ever remain the same, the resistance occasioned by imperfections in the road and carriages will be reduced by every prospective improvement in their construction; thereby increasing the *proportionate* effect of gravity, and making the line of direction still more subordinate to that of draught, or, in other words, increasing the length of level road that may be traversed with the same expenditure of power as would raise the load up a given elevation. Curves increase the resistance to the motion of carriages, and add to the risk of accident; but if slight, they increase the length of the road much less than might be supposed. Edgeworth, in his 'Essay on the Construction of Roads and Carriages,' says, "A road ten miles long, and perfectly straight, can scarcely be found anywhere; but if such a road could be found, and if it were curved, so as to prevent the eye from seeing farther than a quarter of a mile of it, in any one place, the whole road would not be lengthened more than one hundred and fifty yards."

The principle explained in the article Railway, of so arranging the inclinations on each side of the summit, or highest point unavoidably passed over, that there may be no unnecessary rise and fall, is equally deserving of attention in the design of a common road, although it has been much neglected. The following statement respecting an old road in the Isle of Anglesey, which was altered by Telford, shows how very much a road may be improved by judicious alterations; not only by shortening the line and lowering the summits, but also by diminishing the minor undulations:—

	Summit above high water.	Total rise and fall.	Length.	
			Miles.	Yards.
Old road . . .	339 feet	3,540 feet	24	428
New road . . .	193 ,,	2,257 ,,	21	1,596
Difference . . .	146 feet	1,283 feet	2	592

However desirable a perfect level may be in theory, a road with moderate inclinations, as of 1 in 100, is found to be preferable in practice, because without such a slope it is difficult to get rid of water fast enough, unless the road be raised a few feet above the surrounding land, and thereby exposed to the free action of sun and wind. Slight undulations are also considered, by most authors, to be desirable in all cases where animal power is employed; frequent changes in the nature of exertion being considered favourable to the horses. On this principle it is recommended that where an undulating road is reduced to a uniform gradient, occasional levels should be introduced to ease the draught. Any inclination exceeding the angle of repose, or that beyond which a carriage would roll down by its own gravity, occasions a loss of power; but all below it are attended with a compensating effect when the traffic in both directions is taken into account; the advantage gained by descending carriages being equal to the additional labour required in the ascent. This angle has been stated by Lardner to be about 1 in 40, with a good carriage on a broken stone road of the best quality; but the inclination allowed on the Holyhead road is 1 in 35, a slope which may be ascended at a good rate of speed, and descended at twelve miles an hour without risk. A greater slope not only occasions much additional resistance in the ascent, but, by rendering it unsafe to drive down at full speed, causes a loss of time in the descent also. Modern engineers consider it unadvisable in any case to exceed an inclination of 1 in 24, though there are hills at least twice as steep on some turnpike roads. The following table shows the effect of various inclinations in increasing the draught of a stage-coach at different velocities on the same description of road, as indicated by a dynamometer contrived by Mr. Macneill for experiments on the draught of carriages:—*

Inclination.	Force required at		
	6 m. p. hour.	8 m. p. hour.	10 m. p. hour.
1 in 20	268 lbs.	296 lbs.	318 lbs.
1 ,, 26	213 ,,	219 ,,	225 ,,
1 ,, 30	165 ,,	106 ,,	200 ,,
1 ,, 40	160 ,,	166 ,,	172 ,,
1 ,, 600	111 ,,	120 ,,	128 ,,

It should always be borne in mind that the occurrence of one steep hill on a line of road affects the working of the whole stage, as the number of horses required for ascending it must be used, although a portion of their power may be unemployed, on the greater part of the road. The inconvenience of a steep inclination may be diminished by laying a stone tramway for the use of ascending vehicles; a measure adopted with success on the Holyhead road, where, on a slope of about 1 in 20, the power required to draw a ton was reduced by this means from 294 lbs. to 132 lbs.

In arranging the works necessary for obtaining the required level, the preference should be given to embankments; and, wherever it is practicable, the bed of the road should be elevated two feet above the natural level, for the sake of efficient drainage. Tunnels are very rarely introduced on common roads, being very costly, and, when of considerable length, inconvenient from their darkness. When the road is in an excavation, the side-slopes should never be steeper than two horizontal to one vertical, and it is desirable to have those on the south side three to one; because, though many materials will stand at steeper inclinations, it is essential to the preservation of the road, and the comfort of horses travelling upon it, that the sun and air should have free access to its surface. Where stone can be readily procured, the erection of walls at the bottom of the slopes gives a neat and finished appearance to the road, and prevents earth, which may be loosened from the sides, from falling into the side channels or drains. The Highgate Archway road affords an example of the great difficulties that occasionally attend a deep excavation owing to the accumulation of water, the remedy for which is described hereafter. Where embankments are required, strong fencing is especially necessary to guard against the occurrence of accidents. Some of the roads formed by Telford are conducted across deep valleys by bridges or viaducts of great magnitude, in order to maintain the desired level without the inconvenience and expense of large earth embankments.

---

* This useful instrument, which its ingenious inventor denominates a *Road Indicator*, is mounted on a light phaeton, and besides marking the draught at every ten or twenty yards, points out the distance run, and the rates of acclivity or declivity on every part of the road. A full description of it is given in Parnell's 'Treatise on Roads.'

In old roads the bridges erected for the passage of rivers are frequently made much smaller than is advisable, so that the level of the road is made too low, and the water is impeded by the contracted arches to such a degree as to occasion much damage during floods. Modern engineers, by adopting bolder dimensions for the bridges, and forming raised approaches, avoid these inconveniences, and secure their roads from the risk of obstruction by floods. The raising of the road wherever it passes through marshy or low land is a very necessary measure. Many old roads still in use are sunk several feet below the surface of the ground, because they have originally been exposed to the destructive action of water, and the materials thus softened have been ground into mud and cleared away, until, by the repetition of these operations, the roads have been converted into deep trenches, which are frequently flooded in winter. Of the extent to which this process has been occasionally suffered to go on, an idea may be formed from the statement of Edgeworth, that "the stag, the hounds, and the horsemen have been known to leap over a loaded waggon, in a hollow way, without any obstruction from the vehicle."

In conducting a road through a mountainous district, in addition to numerous bridges for the purpose of crossing ravines (for which purpose suspension bridges have been occasionally applied, as in the passage of the Menai strait), embankments between retaining walls of stone, and walls to support the road along the face of a precipice, are frequently necessary. Some works of the latter character have excited much admiration. If the slope of a precipice be only six inches horizontal to a foot vertical, such a road may be formed by building a wall thirty feet high, based on steps cut into the rock, and cutting into the rock to the depth of ten feet on a level with the top of the wall, the space between which and the face of the precipice is filled in with earth or stone. By this means a platform twenty-five feet wide is obtained. Many works of this character have been executed by Telford and other engineers, in various parts of Scotland, in the Highland roads, and those forming the communication between Edinburgh and London; and others, the boldness of which commands universal admiration, occur in the great mountain-passes of the Simplon and Mont Cenis, which form imperishable monuments of the talent and energy of the engineers of Napoleon, by whom they were executed.

When the works are completed to the proper level for receiving the hard materials that form the surface of the road, the earth should be formed into the intended width and a nearly level surface, the footpath or paths being elevated a few inches above the bed of the carriage-way. Thirty feet is the ordinary width of the carriage-way, exclusive of footpaths, of the Holyhead road; but the propriety of reducing the width, in most places to twenty-four or twenty-five feet, has been suggested. This width may be more or less exceeded in the vicinity of large towns, according to the amount of traffic, but should be exactly adhered to in other situations, as uniformity in this particular greatly improves the appearance of a road, and also contributes to economy, both as to the land and materials, and the cost of maintenance. Some engineers recommend that the bed should be made convex, in the same degree as the finished surface of the road; but it is quite flat in the Holyhead road, by which means a greater depth of materials is allowed in the centre than at the sides of the road. Much has been said on the subject of the best form for the transverse section of a road. Formerly it was common to make it very convex, often to a degree that was highly dangerous, with the idea of throwing off water; but this notion is very fallacious, because if a road be allowed to wear into ruts, no degree of convexity that can be given is sufficient to keep it dry; while, if the surface be good, a very moderate slope is sufficient to carry off water, and a steep inclination will cause it to run with such velocity as to wear away the road materials. Another disadvantage of too great an inclination is, that, by throwing the weight of a carriage on one side, the vehicle itself is injured, and the overloaded wheels cut up the road more than necessary. Some have gone so far in opposition to this practice as to advocate perfectly flat or even concave roads, in favour of both of which much may be said; but the general practice of modern road-makers is to make the surface slightly convex. In Telford's roads the convexity is elliptical, the fall being half an inch at four feet from the centre, two inches at nine feet, and six inches at fifteen feet. It has been recommended to form the cross section into three flat planes, that in the centre being horizontal, and the others slightly inclined from it. Very narrow roads are often sloped in one direction only, like one half of a convex road; and roads on the face of a steep hill are occasionally treated in this manner, the surface water being conducted towards the hill, and carried off by drains under the road. This plan has the advantage of checking any tendency in carriages to roll or turn over towards the least protected side of the road.

Wherever the substratum of a road is wet and soft, great care is necessary to make the bed solid. If the ground be boggy or marshy, it is desirable to form an embankment of sufficient thickness to compress the elastic foundation; such embankment being sometimes supported by faggots. Telford and most engineers recommend that ramming with stone-chips should be resorted to where the bed is wet and spongy; and that where soft clay occurs, a stratum of earth or of sand should be laid between it and the road materials, a precaution which tends to diminish the injurious effect of frost on a road with a clay bottom. Though great care is usually considered necessary in order to obtain a firm foundation, McAdam and some others have not only contended against its importance, but actually preferred, in certain cases, a yielding substratum to one of rock, on the supposition that the wear of the road is diminished by elasticity. Careful observations on the repairs of a road in Somersetshire, of which about seven miles are supported by a morass, and five or six by limestone rock, indicated a difference of expense in repair of about five to seven in favour of the morass, though it was so soft that the vibration caused by a carriage passing was sufficient to break the young ice in the side ditches; but extended experience seems to confirm the more general opinion in favour of a hard unyielding foundation.

Deep ditches should be cut for the efficient drainage of the road, which is of paramount importance; and these should be on the field side of the fences. They should extend to a depth of from 2 feet 6 inches to 4 feet below the bed of the road, according to the nature of the ground. The earth thrown out from them is commonly used in forming banks for the hedges; but in wet soils, where the ditches are made larger and deeper than usual, the additional earth excavated is applied to raising the bed of the road. Where brick or stone-covered drains are substituted for open channels, it is usual to build them with open joints, to allow the passage of water through the sides. Cross-drains of masonry are introduced at intervals to connect the side channels, and numerous minor drains filled with rubble stones or clean gravel are formed in the bed of the road. The latter are frequently of the kind called mitre-drains, which are made V shaped in plan, diverging from the centre of the bed, and extending diagonally to the sides, their angle being regulated by the longitudinal slope of the road, so that their inclination may not exceed 1 in 100. These may be placed about sixty yards apart, or closer in wet soils, and they receive the water that filters through the surface materials. In cuttings or excavations it is advisable to make drains to catch the water descending from the sides, and prevent its reaching the surface of the road.

In treating of the choice and application of the hard materials which compose the surface of the road, the formation of *metalled* roads, or those made of broken stone and similar materials, will be first considered; and afterwards that of the principal varieties of pavement.

Metalled or Broken-Stone Roads.—In the formation of metalled roads the system adopted in the great works of Telford and his followers, is the one most generally adopted by English engineers. The distinguishing characteristic of this system is the use of a rough pavement of hand-laid stones on the bed of the road, to support the small broken stone of which the surface is composed. In the very imperfect mode of road-making formerly practised (which scarcely deserves the name of a system), it was very common to cover a bad road with a large quantity of stones, often unbroken, and generally of very irregular dimensions. These stones, owing to their rounded form and the softness of the substratum, never consolidated into a hard surface, and in course of time sunk into the soft earth beneath, which worked up among the stones in the form of mud. Thus enormous quantities of stone were used without producing a good road, the stone sinking into the earth to a surprising extent. This evil is greatly diminished by good drainage, and by the use of stones of uniform size broken into angular pieces, which have a tendency to lock together into a hard and compact mass,—a fact of the highest importance in the science of road-making, and which appears to have been first prominently brought forward by the late Mr. McAdam. A great extent of excellent road has been made on the plan advocated by McAdam, who considered paving unnecessary, and laid the broken stone immediately on the surface of the earth, depending on its forming a hard crust impervious to water, so that the earth, being always kept dry, may have no tendency to work up among the metal or broken stone. McAdam used no stones exceeding six ounces in weight, and gave the preference to those of about one ounce, or an inch diameter, which he spread over the road in thin layers, each being worked over by carriages till in some degree consolidated; and he objected to the use of chalk or earth mixed with the stone for the purpose of binding it together. He considered a thickness of ten inches of broken stone, well consolidated, to be sufficient for bearing any load, even where the foundation is a morass, in which case he considered no intermediate substance necessary. Near Bristol, a road in which the metalling had worn down to a thickness of only four inches, was found to have kept the substratum of earth perfectly dry. But, satisfactory as this plan of road-making has proved in some cases, there are others in which it has failed, and some in which a very large quantity of stone has been applied before a firm road could be obtained. A road from Lewes to Eastbourne, made on Mr. McAdam's principle, is said to have required three feet of materials in many parts before it was consolidated, though it was ultimately brought into a good state.

The system of pitching or paving the bottom of a road has the advantage of preventing the subsoil from working up among the road materials, and, when well executed, of distributing the pressure of carriages over a larger base; while the size of the paving-stones themselves prevents their sinking into the earth, as small stones are liable to do. The pavement also acts as a drain to the surface materials. In addition to these, the plan has, in many situations, the advantage of economy, as the cost of a pavement is considerably less than that of an equal depth of well-broken stone. In most, if not all, of the cases in which the paving system has failed, the want of success may be attributed to very imperfect execution; as, if the stones are very irregular in size or badly set, or the thickness of metal is insufficient to protect the pavement from the shake of passing carriages, the stones become deranged, and the subsoil, working up among them, quickly spoils the road.

The case of the Highgate Archway road, which has been before alluded to, is a remarkable illustration of the absolute necessity of a firm bottoming under some circumstances. This road is over a subsoil of sand, clay, and gravel, and, being partly in a deep cutting (originally intended for a tunnel), is much exposed to the influx of water. The road, which is rather more than a mile and a half long, was originally made of a quantity of gravel and sand laid on the natural soil, and covered with broken flints and gravel; but this plan not succeeding, the road was taken up, and pieces of waste tin were laid on the subsoil, over which were spread gravel, flints, and broken stone. This expedient did not produce the desired effect, and at length, in 1829, the road was placed under the management of the Holyhead-road Commissioners, its proprietors having failed, notwithstanding an enormous outlay, and the application of 1200 cubic yards of gravel annually, to bring it into a satisfactory state. A thick coat of broken granite was spread on a portion of the road; but, owing to the unsoundness of the foundation, it never consolidated, the stones wearing into smooth pebbles by their attrition against one another, even down to the bottom of the mass. The commissioners therefore determined, as paving stones could not be procured without great expense, to lay a coating of Roman cement and gravel as a bed for the road-metal, an experiment which was attended with complete success. The work was executed by Macneill, and consists of a composition of Roman cement with eight times its quantity of washed gravel and sand, which, after being mixed in a box, was laid on the bed of the road to a thickness of six inches and a width of about eighteen feet. A few minutes after being laid, the upper surface was indented, by means of a triangular piece of wood sheeted with iron, with numerous channels or grooves, sloping about three inches from the centre to the sides, these channels serving for the stones to lie and fasten in, and for conducting any water that might percolate through them into the side drains. This measure, combined with an extraordinary extent of drainage, amounting in the whole to a length of 12,803 yards, proved so complete a remedy that, in the first winter after the cement was laid, coaches were able to go up with four horses at a trot with the heaviest loads, though before the improvement six horses had mounted with difficulty at a walking pace. The effect of the alteration on the wear of the road was equally satisfactory, four inches of quartz being worn away on the old bottom while only half an inch of the same stone was worn where laid on the cement foundation. The expenses of laying the cement composition, including the formation of the bed of the road, was about ten shillings per lineal yard, part of the gravel used being old. Macneill estimated the cost at from twelve to fifteen shillings per yard if new gravel were purchased.

The effect of a paved or concrete foundation in diminishing the draught appears, from the subjoined statement, founded on experiments with Mr. Macneill's road indicator, to be very great; but a more extensive series of trials is desirable for a comparison of different systems under various circumstances. The draught of a waggon weighing 21 cwt. was found to be as follows:—

On a well-made pavement	33 lbs.
On a road with six inches of hard broken stone on a rough pavement	46 „
On a similar road, with a foundation of Roman cement and gravel in lieu of pavement	46 „
On a road with a thick coating of broken stone on earth . .	65 „
On a road with a thick coating of gravel on earth . . .	147 „

For the formation of the pavement of a metalled road, almost any hard stone that may be easily dressed with the hammer may be used. The stones should be tolerably regular in size, and laid in rows with their broadest face downwards, the interstices being carefully filled up with stone-chippings, so as to pin the whole pavement together, and effectually prevent the earth from working up through the joints. In one of Telford's specifications for the Holyhead road, the dimensions of the stones for a pavement 30 feet wide are given as 7 inches deep in the middle of the road, 5 inches at 9 feet from the centre, 4 inches at 12 feet, and 3 inches at 15 fifteen feet, the stones to be laid lengthwise across the road, and the upper edge in no case to exceed 4 inches wide. All irregularities are to be broken off by the hammer, and the stone-chips used in packing the joints are directed to be wedged in by hand or with light hammers. No ramming is necessary, and it is desirable to prevent carts which are used in the conveyance of the road materials from being drawn upon the pavement before it is covered with broken stone.

Some road-makers use a pavement even on a substratum of rock, where it is uneven, but in many cases it is unnecessary; although, if the surface be smooth, it should be picked to a degree of roughness similar to that of a pavement, in order that the road materials may not slide upon it. Where paving the whole width of a road might be too expensive, the pavement is sometimes limited to a width of 16 or 18 feet in the centre. In situations where coarse stone of suitable quality can be easily procured, it is found to be cheaper to make a road with 6 inches of broken stone and a pavement, than with 10 inches depth of broken stone without paving. Mr. Wingrove, surveyor of the Bath roads, mentions the use of freestone brash, chalk, &c., for forming the foundation pavement of metalled roads. Of late years burnt clay ballast has been substituted for rough stone pavements in the brick earth or blue clay districts around London, with considerable success.

The quality and right application of the road-metal, or broken stone, which forms the surface of the road, is of great importance. As a general rule, the hardest stone is to be preferred; but this rule admits of some qualification, some very hard stones being found to wear much more rapidly than others of a softer but tougher quality. According to Parnell, whose experience rendered him a good authority, the best descriptions of road materials "consist of basalt, granite, quartz, syenite, and porphyry rocks." The whinstones found in different parts of the United Kingdom, Guernsey granite, Mountsorrel and Hartshill stone of Leicestershire, and the pebbles of Shropshire, Staffordshire, and Warwickshire, are among the best of the stones now commonly in use. The schistus stones will make smooth roads, being of a slaty and argillaceous structure, but they are rapidly destroyed by wet, by the pressure of wheels, and they occasion great expense in scraping and constantly laying on new coatings. Limestone is defective in the same respect. It wears away rapidly when wet, and therefore, when the traffic is very great, it is an expensive material. Sandstone is much too weak for the surface of a road; it will never make a hard one, but it is very well adapted to the purpose of a foundation pavement. Flints vary very much in quality as a road material. The hardest of them are nearly as good as the best limestone, but the softer kinds are quickly crushed by the wheels of carriages, and make heavy and dirty roads. Gravel, when it consists of the pebbles of the hard sorts of stones, is a good material, particularly when the pebbles are so large as to admit of their being broken; but when it consists of limestone, or sandstone, it is often a very bad one; for it wears so rapidly that the crust of a road made with it always consists of a large portion of the earthy matter to which it is reduced. This prevents the gravel from becoming consolidated, and renders a road made with it extremely defective with respect to that perfect hardness which it ought to have." Mr. Stevenson, in the article 'Road,' in the 'Edinburgh Encyclopædia,' states the distribution of road materials in the British islands to be partial and irregular. "Throughout Scotland, and even as far south as the approaching sources of the rivers Tees and Ribble, good road-metal is generally to be met with, containing the numerous varieties of granite, greenstone, basalt, porphyry, and limestone. South of this boundary, as far as the Trent and the Dee in Cheshire, the formation is chiefly carboniferous sandstone, and the softer varieties of limestone. In the southern counties chalk and gravel soils chiefly occur, affording flint and gravel, both of which, under proper management, make excellent roads. In North and South Wales we have all the varieties of road-metal which are common to Scotland. In Ireland they have excellent road materials, as granite and limestone are pretty generally distributed."

An interesting experiment has been tried on a part of the Holyhead road between London and Birmingham, as to the effect of iron amongst the road-metal in diminishing the wear of the road. The iron is cast in the form of cubes, about an inch square, and when the road was consolidated, holes large enough to receive them were picked in its surface. A single cube was then placed in each hole, so as to be level with the road, and the small stone-chips were beat down about the iron with a mallet. One of these iron cubes is placed in every four inches of surface. They very soon become firmly imbedded, so as not to be disturbed by the rolling of carriages or the feet of the horses; and to assist their consolidation, it is recommended to water the road freely, if the cubes should be inserted in dry weather. The iron was applied in March, 1835, since which time the portion of road in which they are used has continued in excellent repair, and the wear is materially diminished. Mr. Macneill, the patentee of this method of road-making, considered it particularly applicable to streets, on account of its durability, and believed that the expense would be trifling, as iron of the worst quality might be used. It may be observed that the draught on the piece of road on which the experiment is made is very easy, and that horses do not show any tendency to slip upon it.

In the choice of materials, the expense of conveying them to the road must be taken into consideration, but it is often better economy to fetch good stone from a great distance than to use that which is less durable, though readily procured; as, in addition to the expense of frequent repairs to a road formed with weak materials, great additional labour is imposed upon the horses, which have to wear down repeated coats of fresh stones. This is one of the points in which the inexperience and ignorance of road surveyors have often been displayed, cases having occurred in which an inferior material has been procured from a distance at great cost, while stone of excellent quality existed in abundance on the spot.

With regard to the best size of the broken stone for the surface of a road, both Telford and McAdam direct that no piece should exceed six or eight ounces in weight. In some districts the surveyors have been instructed to test the metal by a pair of scales and a six-ounce weight; but a more usual test is an iron ring 2½ inches in diameter, attached to a handle, through which every stone should be small enough to pass. Some writers have recommended that one inch should be the maximum diameter, but it is only the hardest and toughest materials that will bear breaking so small without much waste. The pieces should be as nearly cubical as may be, and should on no account be broken on the surface of the road; nor is it well to do it on the heap, the best method being to break one or two pieces at once on a large block of hard stone, the pieces being held steady by the iron ring that serves as a gauge. A sitting posture is considered best for those engaged in breaking road-metal, an operation which, under the modern system of road-making, gives employment to a great number of hands. Attempts have been made to perform this operation by machinery, but mechanical contrivances have not been found equal to manual labour. Pronged shovels are made use of in lifting the broken stone into barrows and carts, as they save labour by entering the heap with less resistance than ordinary shovels, and also prevent the admixture of earth with the metal.

The depth of metal on a paved foundation should be not less than 6 inches, and it should be laid on in two or three distinct layers, carefully spread with broad shovels, and carriages should work on each till it is in some degree consolidated before another is laid over it. While the metalling is fresh, men should attend to rake it in the ruts as fast as they are formed, and to pick off any large stones that may have previously escaped notice, as they are sure to work up to the surface. The sides of the road may be covered with the smaller portion of the metal, separated by a sieve with meshes of an inch square; and a layer of about an inch and a half of clean gravel is occasionally added over the whole surface in order to ease the draught while the road is new, though its effect on the road is rather injurious than otherwise, nothing being needed to bind the metal together. Rolling a road on which fresh materials have been laid is a measure of doubtful utility, the most effectual consolidation being produced by the working of carriages which are compelled to vary their tracks, and to run on the new metal, by placing wooden trestles across the road, and altering their position when necessary; the road is frequently raked as long as any loose stones remain.

Where the traffic is not sufficient to justify so expensive a mode of formation as that which has been described, good roads may be formed with broken stone only, increasing in thickness from 6 inches at the sides to 12 inches in the centre. If nothing better than gravel can be procured, Parnell recommends that a coat of 4 inches be laid on the prepared bed, and worked over till pretty firm; then a layer 3 inches thick, once screened, and finally three distinct layers of the gravel well riddled, and free from earth, clay, or stones exceeding an inch and a half in diameter; the road, when completed, to be 10 inches thick at the sides, and 16 in the centre, where the strongest and best part of the gravel should be laid. The drainage must be particularly attended to in a gravel road. Among the inferior materials occasionally used is limestone burnt to a vitreous state; but though formerly often used in districts where coal is abundant, it is not approved for carriage-ways by modern road-makers.

In completing a road it is necessary to form the side channels with care, and to provide against their being interfered with by branch or field roads. The footpath, which is usually about 5 feet wide, may be made of gravel or broken sandstone, and is required in the Holyhead road specifications to be level with the centre of the road, which is 6 inches above the sides. For fencing, walls are preferred where stone is plentiful, as they occupy less space than hedges, and have a neat appearance. If the stone should be of favourable shape, such walls may be built without mortar, except in the coping; but if on the side of an embankment, the walls should be always strongly built with mortar. A hedge-bank and ditch occupy a width of about 8 feet in ordinary cases, and the young quicks are protected by post and rail-fencing; but where timber is scarce, it is sometimes well to make the ditch and bank rather larger, so that the wooden railing may be dispensed with. In cuttings and some other situations a mound or bank without a hedge forms a convenient fence, and these, as well as hedge-banks, may be improved in appearance and durability by being swarded. All fences should be kept low, that they may not exclude sun and wind; and for the same reason trees or buildings that overshadow the road should be removed when practicable. The situation of toll-gates must be regulated by circumstances, but it is very desirable to avoid placing them either on, or at the bottom of, a hill, because such an arrangement is very liable to cause accidents. The gates, which, when single, may be 15 feet, or, when double, without a centre-post, 24 to 30 feet wide, are usually painted white, that they may be readily seen at night. They should be well lighted, and supplied with comfortable toll-houses, which, on some of the modern roads, are erected in an ornamental style. Parnell advises the use of milestones of light-coloured stone, and of larger dimensions than usual; but cast-iron posts have been extensively used, and on some roads cast-iron tablets mounted on stone. A convenient arrangement is a stone or post with two tablets inclined towards the road, so that persons travelling in either direction may see the distance of the town which they are approaching.

However well a metalled road may be made in the first instance, its preservation in a good state depends greatly on prompt and judicious repair. The mud that forms on the surface in wet weather should be scraped off and formed into heaps at the side (avoiding the side channels), until it is sufficiently dry for carting away: because, if left on the surface, it would, while moist, soften the road and cause it to break up, and after drying impede the running off of water from a subsequent shower. This operation has been usually performed by hand, but scraping-machines, patented by Messrs. Bourne and Harris, have been introduced with partial success, and have been said to diminish the labour fully one-half. The winter season, from October to April, is considered the best time for the addition of fresh materials, which are laid on in thin coats, and should always be applied as soon as any hollow capable of retaining water is observed. For the purpose of keeping a supply of broken stone always at hand, depôts for holding about twenty-four cubic yards of metal are formed by the road-side, at intervals of a quarter of a mile or less, from which the stone is taken to the required spot in barrows. When laid on the road, according to Parnell, it is not necessary to pick up the old surface, as the new metal keeps the part under it wet and soft, and soon works in. McAdam, however, recommended breaking up the surface of the road in every case where fresh stone is added.

Stone and Iron Tramways.—Though an improvement on ordinary pavement, this description of road may be considered as a link between metalled and paved roads, stone tracks having been occasionally applied to common roads, and with great benefit. Stone tramways consist of wheel-tracks formed of large blocks of stone, usually granite, the surface of which is made so smooth as to offer very little resistance to the rolling of the wheels, while the space between the tracks, being composed of broken stone, gravel, or rough pavement, affords secure footing for the horses. Iron tramways, in which cast or wrought iron plates are used instead of blocks of stone, have hitherto been very little used on ordinary roads, though their superior smoothness gives them a decided advantage, while their expense does not, as stated by Macneill, at all exceed that of granite. Iron tracks are sometimes made with a flat surface, but a slight concavity, as in Woodhouse's rail, which tends to keep the carriages more accurately in the right course, and is therefore an advantage when the vehicles used on the tramway are nearly uniform in width. The granite blocks used for stone tramways are generally from 3 to 6 feet long, 12 to 18 inches wide, and 8 to 12 inches deep. Great care is necessary in bedding such large blocks; and the joints require nice adjustment. They are frequently laid end to end without any fitting into each other, but it has been proposed to dovetail the ends together, to insert a small stone as a dowel between two blocks, to use iron clamps, or to join the stones with oak tree-nails. The granite tracks used on some steep ascents in the Holyhead road are bedded on a pavement 8 inches thick, packed and grouted, and a layer of 3 inches of broken stones not exceeding 1½ inch in diameter; a thin stratum of gravel, well rolled, being placed last of all to receive the blocks. When they are laid, the centre and side spaces are filled up with ordinary road material to the level of the tracks; a row of common granite paving-stones, about 6 inches deep, 5 wide, and 9 long, being laid along each side of the tracks to prevent loose materials working on to them. Mr. Stevenson, in the 'Edinburgh Encyclopædia,' recommends the use of smaller stones, as being cheaper and less liable to injury from vibration than those of the usual size. The dimensions recommended by him are 14 inches deep, 18 inches wide at the base, 12 inches wide at the top, and 6 to 9 inches long. The increased accuracy required in the numerous joints might probably counterbalance any advantage gained by the adoption of small stones.

The great saving of power effected by the use of tramways for ordinary carriages is shown by numerous experiments, some of which, tried on the granite tracks of the Commercial Road in London, proved that a well-made waggon will run with increasing velocity, by the force of gravity alone, down a mean slope of 1 in 155. On this road a loaded waggon weighing ten tons was drawn with apparent ease by a single horse, up an ascent of 1 in 274, for a distance of about two miles. On an iron tramway laid in 1816 by the Forth and Clyde canal company at Port Dundas, near Glasgow, a horse has taken a load of three tons on a cart weighing nine cwt., up an acclivity of 1 in 15, without difficulty, though he could not proceed with it on a common causeway with an easy line of draught; and the carters agree that the horses take up three tons upon the iron tracks as easily as they did twenty-four cwt. on the common causeway previously used.

In order to ascertain the comparative durability of different kinds of stone for tramways, and for paving generally, Mr. Walker tried some experiments on blocks laid in a toll gateway on the Commercial Road tramway, the results of which were as follows:—The blocks were 18 inches wide and 12 deep, and were laid down in March, 1830; and the loss given in the table was ascertained after they had been in use seventeen months, in August, 1831:—

Description of Stone.	Loss of Depth. Absolute.	Loss of Depth. Comparative.
Guernsey	·060 in.	1·000 in.
Herm[*]	·075	1·190
Budle[†]	·082	1·316
Blue Peterhead	·131	2·080
Heyton	·141	2·238
Red Aberdeen	·159	2·524
Dartmoor	·207	3·285
Blue Aberdeen	·225	3·571

Stone tramways have been adopted in many street pavements where a great traffic is carried on, particularly in some of the narrow streets in the city of London, with much advantage; but their application to acclivities on ordinary roads has hitherto been more limited than their merits deserve. By their judicious introduction on a few steep inclinations, many hilly roads might, at a small expense, be made nearly equal to level lines; and it is probable that such a measure would tend, in an important degree, to enable turnpike-roads to meet the formidable rivalry of railways. In his report to the Holyhead-road Commissioners in 1830, Mr. Macneill strongly recommends the application of stone or iron tracks to several hills, and states that an iron tramway laid down along the whole length of the road would reduce the expense of horse labour fully one half. "If," he writes, "a tramway were constructed of iron plates, the whole way from London to Birmingham, a coach carrying sixteen passengers might be drawn at the rate of ten miles an hour with only two horses, and one horse would be able to draw a post-chaise more easily than two now can, so that the expense of travelling might be reduced one half, and a similar reduction might be made in the charges for carrying goods. The expense of forming such a railway would be about 2500*l.* a mile, making the whole expense from London to Birmingham 271,000*l.*" In addition to the immediate advantages of such an improvement, it would remove one of the greatest obstacles to the successful use of steam locomotives on common roads.

Pavements.—The formation of paved roads on correct principles appears to have been well understood by the Romans, whose pavements show great care in their essential features,—a good foundation and accurate fitting of the stones. Some of the modern imitations of the Roman system in the street-pavements of Italy show the like attention to these important points, the paving-stones being set in mortar on a concrete foundation with a degree of accuracy that has led some writers to designate these roads *horizontal walls.* In some instances the blocks of stone used are of considerable depth; but they are often thin, and, being of large dimensions, have more the character of flag-stones than of ordinary paving blocks. At Naples and Florence, stones 2 feet square and 6 inches thick, laid diagonally across the road, and neatly set in Pozzuolano mortar, are used; the surfaces being chipped where declivities or turnings occur, to prevent the slipping of horses, which become very sure-footed from habit. Occasionally, as at Milan, different kinds of paving are laid for the wheel tracks and horse-path, so as to produce the effect of a stone tramway. These pavements have been recommended as models for imitation in paving the streets of London; but the durability with which they are constructed would form a disadvantage in a place where the pavement has to be frequently disturbed for the purpose of laying down or repairing water and gas-pipes, or cleansing the sewers; and it is probable that pavements which answer well for the light vehicles and limited traffic of many of the continental cities, would be found quite inadequate to bear the number of heavy carriages traversing the principal thoroughfares of the metropolis; of which some idea may be formed from the fact that from six o'clock, A.M., of March 16, to six o'clock, A.M., March 17, 1850, there were observed to pass over London Bridge, 4483 cabs, 4286 omnibuses, 9245 waggons and carts, and 2430 other vehicles, or 20,444 in all.

Another description of paved road, the origin of which is commonly referred to the Romans, is the *chaussée*, or roughly-paved causeway used in the principal highways of France and some other parts of the Continent. This kind of road has been much recommended for its durability when well made, but, unless laid with a degree of care that would render it too expensive for general adoption, it causes a very unpleasant and fatiguing jolting. In such roads the pavement usually covers only a part of the breadth of the road, leaving the sides available for the use of the light carriages in dry weather; and it has been suggested, that where the width of the roadway would allow, it might prove advantageous to form, in all great roads, a track of pavement or hard broken stone for winter use, and another of inferior materials for summer, both to save the wear of the hard road and increase the comfort of passengers. Such an arrangement is convenient in the principal approaches to great towns, where it is considered best to have the pavement at the sides, that carters may walk either on or near the footpaths, and that foot-passengers may not be incommoded by the dirt of the metalled road.

In Holland, pavements of brick, which are also probably derived from the practice of Roman engineers, are extensively used, not only for footpaths, but also for the passage of heavy carriages, which run on them with great facility. The bricks used for this purpose are thin, and well bedded in lime.

Common stone pavements are, by most writers, divided into two classes: *rubble* causeway, in which the stones are of irregular shape, and very imperfectly dressed with the hammer; and *dressed* causeway, which is formed of stones of larger size accurately squared and dressed. In both kinds the excellence of the pavement depends greatly on the firmness and evenness of the bed, and the careful fitting of the stones to each other, which may be accomplished with very irregular stones by judicious selection. If one stone be left a little higher or lower than those adjoining it, or if it become so in consequence of defective bedding, the jolting of carriages in passing over the defective place will quickly damage the pavement; the wheels acting like a rammer in driving the depressed stones deeper into the earth, while the derangement of the lateral support that each stone should receive from those adjoining it, occasions the dislocation of the pavement to a considerable distance, and the consequent working up of the earth through the disturbed joints. Defective joints form another fruitful source of injury and inconvenience both to the pavement itself and to the vehicles jolted over it. If, as is often the case in inferior pavements, the edges of two adjoining stones do not meet with accuracy, narrow wheels will have a tendency to slip into the joint, and by doing so, to wear the edges of the stones, till, as may be frequently seen, the surface of each stone is worn into a convex form that renders the footing of horses insecure, and causes the motion of vehicles drawn rapidly over them to consist of a series of bounds or leaps from one stone to another, accompanied by a degree of lateral slipping highly injurious to the carriage, while the irregular percussion produced tends greatly to the destruction of the pavement.

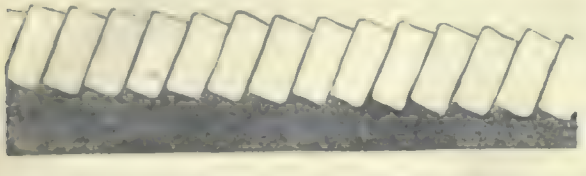
In order to procure a firm foundation, and to prevent earth from working up between the stones, it is advisable in the first instance to form a good carriage-way of gravel or broken stone, and to allow it to be used by carriages till consolidated, before laying the pavement. This plan is stated by Edgeworth, in his 'Essay on the Construction of Roads and Carriages,' 1817, to have been practised successfully by Major Taylor, of the Paving Board, in some pavements in Dublin, and it is strongly advocated by more recent road-makers. Where broken stone is laid to a considerable depth, it should, as in the case of metalled roads, be applied in thin layers, each being separately worked into a compact state. In streets of very great traffic, it is a good plan to lay a sub-pavement of old or inferior stones, bedded on broken stone, as a foundation for the surface pavement, a measure which has been practised with advantage in Paris; but of late years it has been the custom in London to form the bed of paved roads by means of a layer of gravel, perfectly clean, which is rudely converted into a species of concrete by floating the surface with lime-water. The bed of the pavement should be formed into a slight convexity, the slopes being about 2 inches in 10 feet. A thin coat of gravel or sand laid immediately under the paving blocks is of use in filling up slight irregularities in their shape, and enabling them to form a compact bed.

For the paving stones hard rectangular blocks of granite are preferred, though whinstone, limestone, and even freestone, may be used. Guernsey granite, as shown by the table in a previous column, appears to be the most durable, but it is more liable to become inconveniently smooth than some stones of inferior hardness, such as the Mount Sorrel or Aberdeen granite. The stones may vary, according to the traffic, from 6 to 10 inches deep, 6 to 18 inches long, and 4 to 18 inches wide; but it is very essential that the depth of all the blocks in one piece of pavement should be alike, and that where the width is unequal, the stones be so sorted that all used in one course should be uniform in this particular. The accurate dressing of the stones is a point often too little attended to; and an injudicious mode of forming contracts for paving, in which the payment has been by the square yard of paving laid, has, in connection with the effect of competition in bringing prices below the remunerating point, led to the use of stones in which the base is smaller than the upper surface, and which, when laid, scarcely come in contact with each other except at their upper edges. In some pavements the stones are made smaller at the top than the bottom, the joints being filled up with stone-chips, concrete, or an asphaltic composition; and in those of the more common construction the sides of the stones are occasionally hollowed, so as to receive a small quantity of gravel or mortar, which serves as a kind of dowelling. Ramming the stones with a heavy wooden hammer is a practice that has been much recommended, and it is considered that a more efficient application of the process, by means of a ramming-machine, or *portable monkey*, would remove some of the defects arising from imperfect bedding; but when the stones are well laid, and bedded in strong mortar, as the best recent pavements are, a few blows with a wooden maul of about 14 pounds weight are sufficient to fix them firmly in their place. Grouting with lime-water poured all over the pavement facilitates the binding of the whole together, and fills up the joints, so as to effectually prevent the working up of the substratum. The blocks are commonly laid in rows across the road, the joints in each row being different from those of the adjoining ones; but pavements of superior smoothness have been laid in courses stretching diagonally across the street, by which means all the joints are passed over by carriages with greater ease. This arrangement is particularly desirable at the intersection of streets, as it diminishes the risk of horses slipping. Longitudinal courses are objectionable on account of the tendency of narrow wheels to enter the joints. In paving steep inclinations, it is well to use narrow stones, on account of the number of cross-joints; or, if large stones be used, to cut deep furrows across their surface, to afford secure footing. A plan of paving for such situations, which has been found very effectual, is represented in the annexed diagram, in which the stones are so inclined as to present a series of steps. The chief objection to this plan seems to be the jolting caused to carriages, which produces so deafening a noise that, in one instance, such a pavement was taken up at the request of the inhabitants of the street. Many patents have been procured for plans of forming stone pavements in which the pressure of carriages might be simultaneously distributed over several stones, by various contrivances for dovetailing and otherwise fitting the stones together; but such plans are generally too complicated, requiring an accuracy of formation that would be very expensive, owing to the hardness of the stone. Thin blocks of stone, bedded in asphalte, have been tried, and appear to make a good pavement.

---

[*] Herm is an island adjoining Guernsey.

[†] A whinstone from Northumberland. All the rest are granites.



When completed, a thin coat of gravel spread over the surface is useful in diminishing the effect of the jolting of carriages on the new pavement. In case of taking up any part of a pavement to attend to water-pipes, &c., great care is necessary in relaying the part, in doing which it is well to apply some fresh broken stone to the bed, and to lay the paving stones without mortar, until the foundation is settled.

The serious defects of the common stone pavements have led to a variety of experiments on other methods of forming carriage-ways suitable for streets, of which the adoption of broken stone, or macadamised roads, has been the most general. Opinions differ widely as to the propriety of this measure, but an idea seems to be gaining ground that the comparative quietness of such a road, and its superior ease to passengers, are insufficient to counterbalance the increased draught of carriages, the dust of summer, the mud rapidly formed in wet weather, and the great expense of keeping in repair a metalled road when subjected to the constant wear of a busy town.

The enormous expense of maintaining some of the metalled roads in London has led to attention being given to various plans of paving with wood. A very coarse kind of wooden road, consisting of rough logs laid close together across the track, is much used in North America, under the name of *corduroy roads*, but the wooden pavement, properly so called, seems to have been first used in Russia, and tried on a limited scale at Vienna, New York, and some other places, within a few years. One of the earliest kinds used consists of blocks of fir or other wood cut into hexagonal cylinders, of 6 or 8 inches diameter, and from 8 to 12 or 15 inches deep, and placed close together, with the grain vertically. The blocks are sometimes tarred, or may be kyanised; but even where no such precaution is used, the wear is very trifling, as the swelling of the wood from moisture makes the joints very tight and impervious to water. Such a pavement is very smooth when first laid, but unless the foundation be very carefully prepared, it is liable to sink into hollows like the common stone pavement, owing to the want of cohesion between the individual blocks, a deficiency which it has been proposed to remedy by pegging or dowelling the pieces together, though their form is not very suitable for the purpose. Some specimens have been laid on a flooring of planks, to avoid this inconvenience. Numerous other systems of wood pavements have been adopted, but in spite of the incidental advantages (as in the case of the suppression of noise, &c.) they have been found to be so dangerous to horses as to render it necessary to abandon the use of that material.

Another description of road that has lately attracted much attention is that consisting of an asphaltic composition. Many attempts have been made to form roads of gravel and other materials united by natural oleaginous or gelatinous substances, or coal-tar, into a kind of concrete; but such attempts have seldom proved successful on a large scale. Mineral substances of similar character have proved more advantageous, and the native asphalte procured near Seyssel, in the department of l'Ain, and some other places, has been found to produce, when mixed with a small portion of native bitumen, a substance admirably adapted for the formation of smooth roads, and a variety of other important purposes. Its application to carriage-ways has been in this country chiefly confined to court-yards, for which, as well as for terraces and footpaths, it is very suitable. The asphaltic mastic of Seyssel, as prepared for use, consists of ninety-three parts of native asphalte reduced to powder, and seven parts of bitumen; the two being melted together, and a little fine gravel or sand stirred in with the mixture. The composition is ready for use when it simmers with a consistency similar to that of treacle, and it is spread while hot so as to form a coating about an inch thick upon a levelled foundation of concrete. The thickness of the asphalte is regulated by slips of wood or iron, which are often so disposed as to divide the pavement into ornamental compartments, the asphalte being made of various colours by the admixture of different kinds of sand or other substances. Where the ornamental character of the pavement forms a distinguishing feature, beautiful imitations of mosaic work may be executed with asphalte. The genuine natural asphalte possesses a degree of elasticity that renders it exceedingly durable; but artificial compounds in imitation of it generally require too much bitumen, and are injuriously affected by great changes of temperature. Some experiments have been made, but with very indifferent success, on the formation of carriage-ways with large blocks of asphaltic composition containing a considerable quantity of gravel or broken stone. [ASPHALTE.]

Foot-pavements of flag-stones require very little remark. The curbstones should be very hard, and firmly set in cement on a bed of gravel. They usually rise about 6 inches above the surface of the carriage-way, which may be made to abut immediately upon them, without the intervention of a gutter. Where gutters are introduced, those of cast-iron are to be preferred. The flagstones, which should never be less than 2½ or 3 inches thick, are commonly bedded in mortar on a layer of gravel; but sometimes, when there are no cellars underneath, are laid dry. The appearance of many of the new streets of London is greatly improved by the use of flagstones of extraordinary dimensions, extending the whole width of the pavement; and a similar appearance at much less cost may be obtained by the use of asphalte. A slight degree of slope should be given to the pavement, to conduct water to the gutters, for which purpose a fall of 1 inch in 10 feet is sufficient, while a steeper inclination is objectionable from its danger in slippery weather.

Among the substitutes for common Yorkshire flagstones that have been recommended, may be mentioned slate, which appears to be very durable. Some pavements or floors of this material have been laid at the London Docks, where, among other advantages, it is found preferable to wood in point of cleanliness. Trackways of slate 2 inches thick are found strong enough to bear waggons or carts with 4 or 5 tons of goods; and some are laid of only half that thickness on an old wooden floor.

A 'Treatise on Roads,' &c., by Sir Henry Parnell, of which a second edition was published in 1838, may be consulted with advantage by those desirous of obtaining further information on the theory and practice of road-making. The works of Bergeir, McAdam, Edgeworth, Sganzin, Schwilgué, Lehay, and several others; and the various Parliamentary Reports relating to roads from the commencement of the present century, as well as those of the Holyhead Road Commissioners, also contain much valuable matter on this subject. It may be interesting to add, as a means of forming an approximate idea of the importance of our ordinary roads, that the sum laid out in the repairs of the turnpike roads of England and Wales in 1857 was not less than 1,127,791*l.*, including the interest on the debt, or a sum of 182,034*l.*; and that the county roads cost 2,286,559*l.* There are no recent returns of the lengths of the different kinds of roadways, but the cost of maintaining a turnpike road may be taken at 50*l.* per mile, and that of county roads at 11*l.* per mile.

ROADSTEAD, a sheltered bay, or portion of a sea-coast, in which vessels may lie safely at anchor until the tide should allow of their entering the harbour or dock at the bottom of the bay, or to pass the bar of a river discharging into the same. There are other roadsteads upon open coasts, formed by reefs or sand-banks running parallel to, but at some distance from, the shore, which afford shelter from winds blowing in certain directions, and thus materially assist the coasting- trade. Portland Roads and Spithead are illustrations of the first class of roadsteads; Yarmouth and Deal Roads are of the latter class. Plymouth, Cherbourg, and Delaware Bay have been artificially converted into safe roadsteads, and the same result has been attained by the remarkable works executed at the Helder.

The essential conditions of a safe roadstead are, that it should present a large area of water-surface of great depth; that it should have good holding ground; and that it should be protected from all winds which are likely to create much agitation in the water. The entrance must be easy, and indeed it is preferable that there should be more than one entrance to a roadstead, so that a vessel driven by stress of weather may be able to make either the one or the other pass, or, if driven past one of them, may still have a chance of taking refuge in the other. It is precisely for this reason that the roadstead of the port of Vigo is one of the most admirable harbours of refuge in Europe; for the Islas da Bayona stretch across the mouth of the bay, leaving two channels near the shores of the main land, and an overlapped channel between the two islands. The artificial roadsteads at Plymouth and Cherbourg have two navigable passes, for the breakwaters are in both cases formed in deep water, and without connection with the shore; but neither of these marvellous triumphs of human ingenuity and perseverance are so efficient as is the natural screen at Vigo in checking the transmission of the external agitation. In the open roads, such as Deal and Yarmouth, when the wind blows parallel to the shores, or rather to the entrances, no protection whatever can be afforded; and indeed the vessels which may be engaged in such narrow passes, not having sea-room, are exposed to greater danger with such winds than if they were in open sea. To some extent, all roads must be exposed to inconvenience from the waves when the wind blows straight into their entrances; but if the shelter from the prevailing winds should be perfect, it would be found that the waves, driven through the narrow passes, would soon be lost in the large mass of still water behind the natural or artificial means of shelter.

A ship of the line requires a minimum depth of 30 feet, and an area of about 8½ to 10 acres to swing freely at its anchors; a 1000 ton commercial vessel would not require a greater depth than 21 or 22 feet, and the area it would occupy would be proportionally less. If there should be any probability of the transmission of the external agitation to the interior of the roads, the depth of water must be greater than either of those stated, so as to ensure a sufficient depth beneath the keels of the ships even when the waves are at their lowest points. In the best roads, there are usually harbours, docks, repairing slips, and other conveniences for the examination and repair of vessels, and at all times the value of a roadstead is materially increased if it should possess means for watering the ships which resort to it. Some of the best roads in the Mediterranean are of little practical value on account of the lack of fresh water in them; as, for instance, the roads of Cagliari, in the island of Sardinia, although there is a tolerably convenient little harbour at the head of the bay. The passes between the main land and the sheltering breakwater must be at least from 1200 to 2000 yards in width, to allow large vessels to enter easily when they have any heavy way on them.

ROASTING is that culinary process by which meat is brought from a raw to a cooked state more directly by the action of fire than by any other means except that of *broiling*. By the latter the heat is applied immediately and suddenly to the surface, by which it is hardened, so that the juices of the meat are greatly retained, evaporation being thereby prevented; while, by the former, the heat is applied gradually, the watery portion is evaporated, as well as the fat melted out to a considerable extent, till the progressive browning and hardening of the surface prevent the further escape of the juices. But the loss resulting from the evaporation of the watery portion, and to a certain degree, the melting of the fat, may be lessened by imitating in the first stages the process of broiling, namely, by applying the meat at the beginning quite close to the fire, so as to harden the outside, and then removing it to a great distance, and conducting the subsequent stages very slowly. About fifteen minutes is generally sufficient to effect this encrusting for a moderately sized joint, if the fire be brisk and clear, as it always ought to be for roasting, or if gas be used. "Every house should have a moveable piece of iron or steel, with a joint permitting it to be turned out of the way when not in use, screwed on the mantel-piece, with teeth fixed in it, so as to be able to hang the joint any distance from the fire." (Soyer's 'Shilling Cookery for the People.') The evaporation may be further restrained by beginning to dredge the meat with flour earlier than most cooks do. The above eminent authority recommends that "all dark meats, such as beef and mutton, should be put down to a sharp fire for at least fifteen minutes, then remove it back, and let it do gently. Lamb veal, and pork (if young and tender), should be done at a moderate fire. Veal even should be covered with paper. Fowls, &c., should be placed close to the fire, to set the skin." For young meats the process should be carried farther than for older meats. The loss of weight in roasting meat is much greater than by boiling: "By boiling, mutton loses one-fifth, and beef one-fourth; but by roasting, these meats lose about one-third of their weight. In roasting, the loss arises from the melting out of the fat and the evaporation of the water, but the nutritious matter remains condensed in the cooked solid; whereas, in boiling, the gelatine is partly abstracted. Roasted are therefore more nutritive than boiled meats." (Paris, 'On Diet.') The digestibility is also increased, especially in young meats, which are deficient in osmazome, to which the sapidity is mainly owing, and which during boiling passes into the water employed, while in roasting it is powerfully developed and almost entirely retained. "Young and viscid food, therefore, such as veal, chickens, &c., is more wholesome when roasted than when boiled, and are more easily digested." The best and most tender meat may, however, be rendered hard and indigestible by a careless or ignorant cook. Everybody knows the advantage of *slow boiling—slow roasting* is equally important. See Dr. Kitchener's 'Cook's Oracle,' in which the most sensible and racy instructions on this head are given; also in Miss Acton's 'Cookery,' as well as the different works of Alexis Soyer.

The digestibility is increased by the meat being well done, rather than under done; "for though in this latter state it may contain most nutriment, yet it will be less digestible on account of the density of its texture." This is of importance to remember when it is intended for the diet of convalescents, for whom broiled and roast meats are preferable to boiled.

ROBBERY is theft aggravated by the circumstance of the property stolen being taken from the person, or whilst it is under the protection of the person, of the owner or other lawful possessor, either by violence or putting in fear. This offence appears to have been formerly confined to cases of actual violence to the person, but in later times it has been extended to constructive violence by putting in fear, and not only to cases where property has been taken or delivered under a threat of bodily violence to the party robbed or to some other person, but also where the fear has resulted from apprehension of violence to his habitation or to his property, or where it has been occasioned by threats of accusing the party of the commission of an infamous crime.

Robbery was formerly regarded not as an aggravation of the crime of theft, but as a distinct and substantial crime. Latterly, however, robbery has been treated as an aggravation of theft, and it has been held that if, upon the trial of an indictment for larceny, it appear that the taking amounted to a robbery, the party may nevertheless be convicted of the larceny charged.

The stealing is said to be by violence when it is effected by doing any injury, however slight, to the person of the party robbed, or when the act of taking is accompanied by any degree of force for the purpose of overcoming resistance. A snatching or taking of property suddenly or unawares from the person, without some actual injury to the person, does not amount to robbery. If violence be used, it is sufficient to constitute robbery, although resorted to under the colour of executing legal process, or of the exercise of some other lawful authority. It is not essential to the offence of robbery that the violence should have been at first used for the purpose of obtaining the property, provided the violence be unlawful and the property is yielded up, or permitted to be taken, in order to prevent further violence.

Stealing is considered to be effected by threat of violence to the person, when possession of the thing stolen is obtained by any threat, menace, or other act calculated to excite fear or apprehension of violence, present or future, to the person of the party threatened or of any other party in whose welfare the party to whom the threat is addressed may feel interested. It is immaterial whether the threat, &c., be direct or indirect, or whether conveyed by words, gestures, or signs, or whether made under pretence of lawful claim or of acting under legal process or other lawful authority, or of asking charity, or of making a purchase, or under any other pretence. The existence of actual fear in the mind of the party robbed is not material, provided the act of stealing be accompanied by such threats or other acts as are calculated to create the expectation that force will be used in case of resistance. Where no actual violence is employed, and the threats, &c., used do not create any apprehension of violence or expectation that force will be resorted to in case of resistance, or if such apprehension or expectation has ceased to exist at the time when the property is taken, the offence of robbery is not committed. If property be taken by violence or by threats, &c., it is robbery, although the owner may have voluntarily exposed himself to the attack for the purpose of apprehending the offender.

At common law, robbery was a felony punishable by death, without regard to the quantity or value of the property stolen. The offender, however, was entitled to benefit of clergy [Benefit of Clergy], until this advantage was taken away in cases of robbery, under different circumstances of aggravation, by several statutes.

The offender was liable to be punished at the suit of the crown after a trial upon an indictment, and, in certain cases, when taken in the very act, upon a trial without indictment. The party robbed also was entitled to bring his criminal action or appeal [Appeal] against the robber, for the purpose as well of punishing the offender as of obtaining restitution of the property stolen.

The party robbed may without any formality retake his goods wherever he can find them, unless they have been waived or thrown away by the robber during his flight, or seized by the officer of the crown or of the lord of the franchise, or sold in open market. But after such waiver, seizure, or sale, the owner cannot retake them of his own authority. At common law a writ of restitution could be obtained only upon the successful prosecution of a writ of appeal. But the courts before which a party is convicted of robbery or of larceny are now authorised to award writs of, or make orders for, restitution of stolen goods (21 Hen. VIII. c. 11; 7 & 8 Geo. IV., c. 29, s. 57).

Robbery is punishable by penal servitude for life or for any term of years not less than three years, or by imprisonment for any term not exceeding three years, and for any period of solitary confinement during such imprisonment not exceeding one month at a time, or three months in the space of one year.

Upon an indictment for robbery, as well as for any other felony which includes an assault upon the person, the jury may acquit of the felony, and find a verdict of guilty of assault, against the party indicted, if the evidence will warrant such finding; for which assault the party may be sentenced to imprisonment for any term not exceeding three years.

Robbery, in the Roman law, was called Rapina, and the remedy of the injured person was the actio vi bonorum raptorum against the robber. Robbery was, in fact, a species of Furtum; for the definition of furtum was, "a fraudulent carrying off (contrectatio) of a moveable thing against the owner's consent." The word 'fraudulent" comprehended the notion of a person carrying off the thing for the purpose of making it his own. Rapina only differed from Furtum in being effected by force.

Furtum was committed in various ways, besides by taking another person's property. A debtor committed furtum, if he fraudulently carried off a thing which he had pledged to his creditor. It was furtum to use a thing that had been lent, for a different purpose from that for which it had been lent. Furtum was either manifestum or nec manifestum. It was furtum manifestum beyond all doubt when the thief was caught in the act; but there was a difference of opinion as to whether it was furtum manifestum or nec manifestum in a variety of cases. According to some writers, it was furtum manifestum if the thief was taken with the thing before he had reached the place to which he intended to carry it. Furtum which was not manifestum was nec manifestum. The Twelve Tables made the punishment of furtum manifestum a capital offence, that is, an offence the penalty for which affected a person's caput or status. The edict changed this into an actio quadrupli. The remedy in the case of furtum nec manifestum, which the Twelve Tables gave, was an actio dupli, which the edict retained. All persons could have the actio furti who had an interest in the preservation of the stolen thing; consequently others besides the owner might bring the action, a bailee for instance: and sometimes the owner could not bring it, as in the case of bailment, provided the bailee was a responsible person. If he was a responsible person, he was bound to make good the loss to the owner, and consequently could bring the action, and the owner could not. Condemnation in an actio furti was followed by infamia.

The owner of the thing might also bring his action for the recovery of the thing itself or its value.

The law of the Twelve Tables permitted a person to kill a thief who was detected in the act of theft in the night; and a thief might be killed in the day-time, if he defended himself with any weapon (telum). But the severity of the old civil law was gradually mitigated by the edict, and the offence of theft was, as already observed, only punishable by an action of furtum, and the consequent pecuniary penalties.

The Roman law of Furtum is stated in Gaius, iii. 183-209; *Dig.*, 47, tit. 2: *Inst.*, 4, tit. 1.

ROBES, MASTER OF THE, an officer of the household who has the ordering of the king's robes. By statute 51 Henry III., the "Gardein de la Garderobe de Roi," the warden of the king's wardrobe, was to make accompt yearly in the Exchequer, on the feast of St. Margaret. The office has always been one of great dignity. A female sovereign has a mistress of the robes. High privileges were conferred upon the office by King Henry VI., and others by King James I., who erected the office of master of the robes into a corporation.

ROBINIC ACID. An acid of doubtful composition, said to be contained in the root of the *Robinia pseudo-acacia*. It is crystalline and deliquesces in moist air.

ROCCELLIC ACID, ($C_{34}H_{32}O_8$?) obtained from the *Roccella tinctoria*. This acid crystallises in fine colourless needles of a silky lustre. It is insoluble in water, whether cold or hot; alcohol dissolves it readily, 100 parts of 0·819 density, at the boiling-point, taking up 55 parts. Ether also dissolves it easily: it melts at 266°, and solidifies at 251°.

The alkaline roccellates dissolve in water, and yield solutions which froth like soap; but when concentrated, the solutions cannot be drawn out in threads like those of other soaps. Roccellate of potash crystallises in small laminæ: the salt of lime is a white precipitate, insoluble in water, and contains 15·9 per cent. of base.

ROCELLININ. [LICHENS, COLOURING MATTERS OF.]

ROCHELLE SALT. [TARTARIC ACID.]

ROCK ALUM. [ALUM.]

ROCK CRYSTAL, [SILICON.]

ROCK SALT. [SODIUM.]

ROCK-WORK, in gardening, an elevation, composed of earth and other loose materials, and covered with stones and fragments of rock, &c., amongst which plants adapted for such a situation are grown. When the rock-work is managed skilfully, and in accordance with surrounding objects, it may be made to add much to the beauty and interest of the garden. In the first place a proper situation should be selected, and the character of the rocks should harmonise with the situation. Simple outlines and surfaces not broken into fantastic shapes, are best suited to show off the plants. The best stones for rock-work are those which resist the action of the air, and they may be selected according to convenience from the rocks of the neighbourhood in which they are used. The most irregular ought to be chosen, especially those with cavities in them, which may be filled with earth for the growth of mosses, ferns, and small plants. Frequently stones are met with covered with lichens, which, from their picturesque colours, have a pleasing effect. Of these, the *Lichen atroflavus*, *geographicus*, *ventosus*, *perellus*, and *stellaris*, are most common. Such stones are mostly large, and are best adapted for the base of the rock-work.

Although rock-work is intended to present a mountainous or rocky vegetation in a small space, yet there are many circumstances that prevent the growth of true mountain and rock plants in such a situation; but the dry ridges of earth and stones of which it is composed afford a favourable situation for the plants that chiefly occupy the dry soil of plains. On this account, small shrubs and creeping plants of any kind that will grow in a dry soil are selected for rock-work. Of these, the varieties are numerous, and the taste and care of the cultivator may be advantageously shown in the selection.

ROCKET is a cylindrical vessel or case, of pasteboard or metal, attached to one end of a light rod of wood, and containing a composition which, being fired, the vessel and rod are projected through the air by a force arising from the combustion.

Rockets have long been used as a means of making signals for the purpose of communication when the parties have been invisible from distance or darkness, or otherwise inaccessible to each other; and they have occasionally served the important purpose of determining the difference of longitude between two places. In the latter case the rocket is fired at some convenient spot between the stations, from both of which the explosion must be visible; and the latter being nearly instantaneous, the difference between the times at which it is observed, as indicated by chronometers regulated so as to show the mean times at the places, is the required difference of longitude. Rockets have also been constructed for the purpose of being used in warfare, and such missiles were so employed for the first time at the siege of Copenhagen in 1807.

In signal rockets the part of the case which contains the composition, by whose combustion the projectile force is produced, is joined, at the upper extremity, to a conical case containing the composition for producing the explosions or *stars* of light which constitute the signal, and the length of this part is always rather greater than the diameter of the cylindrical part of the case. Such rockets are made to weigh half a pound, one pound, or occasionally even two pounds. The exterior diameter of the one-pound rocket is 1¾ inch; the length of the cylindrical case is 12¾ inches, and the length of the conical head is 3⅓ inches. The rod is generally attached near the base and on one side of the rocket; its length is about 8 feet, or 60 diameters of the rocket, and its thickness is about half a diameter of the latter. The composition with which the cylinder is filled consists generally of saltpetre, sulphur, and charcoal or gunpowder; the whole is reduced to a mealed state, and well mixed together in the following proportions:—saltpetre, 4 lbs.; sulphur, 1 lb.; and charcoal, 1 lb. 8 oz. The composition which produces what are called the stars consists of saltpetre, 8 lbs.; sulphur, 2 lbs.; sulphide of antimony, 2 lbs.; mealed powder, 8 oz.; and isinglass, 3¾ oz. The latter is dissolved in one quart of vinegar, after which one pint of spirit of wine is added, and then the mealed composition is mixed with the liquid till the whole becomes of the same consistency as a stiff paste. It is then moulded into short cylinders, and when dry, these cylinders are packed into the head with a small bursting charge. When the composition of the rocket is burnt out, the burster blows open the head and frees the lighted stars.

The rocket case having been placed on a conical spindle, which passes a certain distance up the centre, the composition for burning is rammed or driven round it, so that in the interior about the axis a void space of a conical form is left in order that a considerable surface of the composition may be at once in a state of combustion. The neck of the rocket (the part to which the rod is attached), is then *choked*, or reduced in size, leaving a small hole or vent through which the fire is communicated to the composition. The combustion of the latter immediately takes place on all the concave conical surface about the void space just mentioned.

In order to understand the cause of the rocket's motion, let it be observed, that if the composition were to be fired within a vessel or case closed on all sides, the pressure of the gas generated would be equal in every direction, and the case would either burst in pieces, or, if sufficiently strong, would remain at rest while all the composition was being consumed. But, the case having an aperture or apertures at the choke or lower extremity of the cylinder, the pressure which would have taken place against that extremity is reduced by the escape of the gas into the atmosphere; and there is an excess of pressure on the head, which is not counteracted by a pressure on the other extremity, equal in amount to the pressure due to a surface of the size of the orifice, that is, disregarding the resistance of the atmosphere to the escape of gas; and this pressure impels the rocket forwards or upwards. This force acts in a manner similar to that by which a gun recoils when the charge is fired; but, in the latter case, the fluid escaping almost instantly from the bore, the force is one of impulse on the bottom of the chamber which ceases nearly as soon as it is generated; whereas, in a rocket, the composition continuing to burn during several seconds, the force of impulse becomes a force of pressure, which continues to act till the material is consumed. Hence it follows that a rocket ascends, or moves forward, with an accelerated motion till the resistance of the air becomes equal to the accelerative force: and when the composition is burnt out, the rocket falls to the ground. We see then that *cœteris paribus*, the larger the vent or aperture, the greater will be the pressure on the head, driving the rocket forward. But this is modified by the consideration that the smaller the aperture the greater will be the condensation, and, therefore, pressure of gas generated; or, in fact, that the gas should not be allowed to escape as fast as it is generated. Again, the more rapidly the gas is generated, or the stronger the composition is, the greater will be the pressure; but at the same time, the sooner will it be burnt out, and the stronger and heavier must be the case. These considerations are most important in the construction of the large military rocket, and will be found fully treated in Captain Boxer's 'Treatise on Gunnery,' p. 67, chapter on Rockets.

The rod serves to guide the rocket in its flight: for the common centre of gravity of the rocket and rod being a little below the top of the latter (in the one-pound rocket it is 2 feet from the upper extremity of the rocket, or 7 feet from the lower extremity of the rod); if we suppose the rocket to be fired vertically upwards, and a vibration should take place about the centre of gravity by any excess of pressure on one side arising from an irregularity in the burning of the composition, the resistance of the air against the long portion of the rod below that centre, like a force acting on the longer arm of a lever, will exceed the force by which the vibration is produced, since the latter force acts on the rocket and the upper part of the rod which constitutes the shorter arm of the lever; and thus the vibration is checked or prevented, and the rocket is enabled to ascend steadily. But, in proportion as the composition burns out, the common centre of gravity approaches nearer the middle of the whole length of the rocket and rod; and the resistance of the air acting at length nearly equally above and below that centre, it can no longer counteract any inequality in the burning of the composition. Thus, in falling, the top of the rocket, or the rocket end of the rod, is downwards.

The rod performs a similar service when the rocket is impelled horizontally or obliquely; for, while the force of projection is great enough to carry the rocket forward, and the centre of gravity of the whole is near the rocket end of the rod, the resistance of the air against the tail of the latter will nearly prevent any vibration; but, when the centre of gravity has got near the middle of the length, the head of the rocket begins to droop, and at length the whole comes obliquely to the ground. It has happened however, from the rod being too short or too light, that the weight of the rocket, when the latter had been projected with a small elevation, has so much incurvated the line of its path before the composition has burnt out, that the rod has turned over it, and the whole has been driven to the ground in a direction tending towards the place from whence it was projected. In signal rockets, the stick is fixed to the side of the cylinder, a very defective arrangement, as shown by Captain Boxer in his chapter on Rockets.

Rockets whose diameters vary from 1 to 2 inches have been found to ascend vertically to the height of about 500 yards; and those whose diameters vary from 2 to 3 inches, have ascended to the height of 1200 yards. The distances at which rockets can be seen vary from 35 to 40 miles; and the times of ascent from 7 to 10 seconds. (Robins's 'Tracts,' vol. ii.)

Rockets, to be employed as military projectiles, were invented by Sir William Congreve, and, in the British artillery service, a body of men, called the rocket troop, was organised expressly for their management. Sir William caused the rockets to be made with strong iron cases of cylindrical forms, and terminating at the head with a paraboloid or cone; and he attached the rod so that its axis should coincide in direction with that of the rocket. Five classes of rockets were first made, namely, 3, 6, 12, 24, and 32 pounders. The 32 pounders have now however been abolished.

The paraboloid head is hollow, and can be used as a shell by filling it with powder, or as a shot by leaving it empty. The 12 and 24 pounders can also be used as carcasses by substituting a conical carcass head with four vents for the paraboloid head. The shell is fitted with a fuze fixed in the base, that is, nearest the rocket composition. It also has a small hole at the apex, through which the bursting charge is introduced. Through this hole the boring bit is introduced when it is necessary to bore out any fuse composition for short ranges. When the ranges are very short, it is necessary to bore out some of the rocket composition also. But this is a dangerous operation and hardly repays the trouble. The stick is screwed into the bottom of the case, an iron disk, and round it are five vents for the escape of the gas. In order that the direction of their flight may be more certain, military rockets are, in general, fired from tubes fixed in stands in such a manner as to be adjustable to any elevation, and raised sufficiently above the ground to keep the stick off it; and the proper elevation, at least for the smaller rockets, is about one degree for each hundred yards in the required range. From their form they penetrate to a considerable depth when fired against timber or earth: 12 pounder rockets, after a range of 1200 yards, have been found to enter the ground obliquely as far as 22 feet. The principal inconvenience attending rocket practice is the powerful action of the wind when it blows in a direction perpendicular, and even oblique, to the intended line of flight. The effect is very peculiar, for the wind acting on the tail, a long lever, drives the head up into the wind. The rocket should therefore be laid to leeward.

Rockets, being much lighter than any other kind of ordnance, and capable of being used with or without carriages, are well adapted for conveyance in mountainous countries. When fired in volleys against troops, their effect is likely to create much disorder; and those which act as carcasses, when fired against buildings, will almost certainly cause their destruction. Besides being employed in the siege of Copenhagen, rockets were used at the bombardment of Flushing (1809); and in 1813 the British rocket-troop rendered considerable service at the battle of Leipzig. The advance of a French column against an inferior force of British troops was checked by a well directed fire of rockets at the passage of the Adour in the last-mentioned year; and it is said that the explosion of the powder-magazine which in 1840 produced such disastrous effects at Acre, was caused by the fall of a rocket on the building. Rockets were used both by the French and English before Sebastopool. A rocket was invented by Mr. Hale a few years ago to be used without a stick; the rocket was something similar to the Congreve rocket, but at the base, which is in form like the frustum of a cone, besides a large vent hole in the axis there were five smaller holes cut obliquely through the exterior surface of the conical part. These holes, termed "tangential holes," are made with the object of giving a rotatory movement to the rocket to keep it point foremost. [RIFLE.] The rocket was restrained by a spring in the tube till it had obtained sufficient initial velocity to prevent its drooping.

ROD. [PERCH.]

ROGATION DAYS. It was a general custom formerly, says Bourne, and it is still observed in many country parishes, to go round the bounds and limits of the parish on one of the three days preceding Holy Thursday; when the minister, accompanied by his churchwardens and parishioners, used to deprecate the vengeance of God, beg a blessing on the fruits of the earth, and preserve the rights and properties of the parish. The primitive custom used by Christians on this occasion was, for the people to accompany the bishop or some of the clergy into the fields, where Litanies where made, and the mercy of God implored, that he would avert the evils of plague and pestilence, that he would send them good and seasonable weather, and give them in due season the fruits of the earth. The Litanies or Rogations then used gave the name of Rogation Week to this time. They occur as early as A.D. 550, when they were first observed by Mamertius, bishop of Vienna, on account of the frequent earthquakes that happened, and the incursions of wild beasts, which laid in ruins and depopulated the city. (Walifred, Stral., c. 28, 'De Repub. Ecclesiast.') In the canons of Cuthbert, archbishop of Canterbury, made at Cloveshoo, in the year 747, it was ordered that Litanies, that is Rogations, should be observed by the clergy and people, with great reverence, on the seventh of the calends of May, according to the rites of the church of Rome, which terms this the Greater Litany, and also, according to the custom of our forefathers, on the three days before the Ascension of our Lord, with fastings, &c. (Wilkins, 'Concil. Brit.;' Spelm., *v.* 'Litania.') In the Book of Common Prayer they are still retained. The three Rogation Days are the Monday, Tuesday, and Wednesday before Holy Thursday, which are appointed fast days. The previous Sunday is Rogation Sunday.

Rogation Week, in the northern parts of England, is called Gang Week, from *to gang*, which in the north signifies to go. Gang-week, occurs in the rubric to John, c. 17, in the Saxon Gospels; and Gang-dagas are noticed in the laws both of Alfred and Athelstan.

ROGUE AND VAGABOND. [VAGRANT.]

ROLLING, ROLLERS. [IRON MANUFACTURE.]

ROLLING STOCK. [RAILWAY.]

ROLLS. [RECORDS.]

ROLLS-COURT, the Court of the Master of the Rolls, is usually held in the Rolls Buildings in Chancery Lane; which were originally a house or hospital for the reception of Jewish converts. When the Jews were banished from England by King Edward I., there was little use for an hospital of this kind; whereupon it was assigned to the Master of the Rolls, who had thenceforth the denomination of *Magister Rotulorum, Recordorum, &c., et Custos Domus Conversorum.* One or two converts were maintained on a poor pittance in this house in the 16th century.

ROLLS, MASTER OF THE, an officer of the Court of Chancery, second only to the chancellor himself. Originally he had, as the name implies, the custody of the rolls or recorded proceedings of that court, and, it seems also, of any other documentary matter belonging to that court. But the custody had long been merely nominal, and the actual care of them was vested in certain keepers, under the authority of an act of Parliament (1 & 2 Vict. c. 94), by which, however, very extensive powers are given to the Master of the Rolls with respect to the custody and use of them. This act further commits to him the records also of the Common-Law Courts and of the Court of Exchequer.

By what means the Master of the Rolls became divested of the peculiar duties indicated by the name, is a point of legal antiquarianism which has not been satisfactorily elucidated; nor is it quite clear when or how he came to sit to hear causes in equity. The chief duties of this officer now are judicial; but from his decrees there is an appeal to the chancellor, or lords justices.

ROMAN ALUM. [ALUM.]

ROMAN ARCHITECTURE. Although, as was said under ARCHITECTURE, the Romans derived their architecture, as they did most of their arts, immediately from the Greeks, yet they undoubtedly borrowed the circular arch, and the fondness for circularity in the plans of their buildings, from the Etruscans; and these features were what mainly brought about the modifications of style and ornamentation, the variety of form and the constructive peculiarities, which distinguish Roman architecture. We cannot here trace the progress of the various modifications: all we shall attempt is to show the leading characteristics of Roman architecture, especially marking its divergence from that of the Greeks, referring the reader to the article GRECIAN ARCHITECTURE for a general view of the parent style, and to COLUMN for a particular account of the Orders.

With regard merely to the orders, Roman architecture presents chiefly a corruption of the Doric and Ionic, for it may claim the Corinthian as almost entirely its own, the Roman examples of that order being not only numerous and varied, but at the same time exceedingly different in character from the almost solitary specimen of one with foliaged capitals which occurs in a Grecian building. [GRECIAN ARCHITECTURE.] But even as regards the application of the orders, there is a wide difference between the two styles; in the Roman they are frequently employed as mere decoration, the columns being *engaged* or attached to the walls, or in some cases (as that of triumphal arches) though the columns are insulated and advanced from the structure, they are in a manner detached from it, inasmuch as they do not support its general entablature, but merely projecting portions of it. Nor are these the only differences, for besides the frequent employment of pilasters as substitutes for columns—that is, as constituting the order without columns—the practice of *super-columniation*, or raising one order upon another, was by no means uncommon; a practice that was indeed a matter of necessity in such enormous edifices as the Colosseum, if columns were to be employed at all.

From all this it will be evident that, as regards the orders alone, there is a very marked difference between Roman and Grecian architecture; yet such difference is by no means the whole. If there were no other distinction between them, that arising from the arch, and diverse applications of its principles to vaults and domes, would be a very material one; but we also meet with a variety and complexity in Roman buildings of which there are no examples in those of Greece.

With the exception of the Erechtheium, or triple temple on the Acropolis of Athens, Greek temples were merely simple parallelograms, differing from each other as to plan only in the number and disposition of the columns around the cella [TEMPLE]; whereas by the adoption of the circular form in their plans, whether for the whole or parts of a building, the Romans introduced an important element of variety into architectural design. To this shape in the ground-plan is to be ascribed the origin of the *tholus*, or concave dome, which harmonizes so beautifully with all the rest, and renders the rotunda-shape at once the most picturesque and the most complete for internal effect,—that in which both unity and variety are thoroughly combined. [ROTUNDA.] The Pantheon alone would suffice to convince us that the Romans were not mere copyists, and that if the Greek orders deteriorated in their hands, they also added much to the art and greatly extended its powers by new appliances. As regards its exterior, the Pantheon presents what is certainly a strikingly picturesque (and what we consider to be also a consistent and appropriate, because a well-motived) combination, namely, that of a rectangular mass projecting from a larger circular one. In that example the body of the edifice, or rotunda itself, has no columns externally; but circular peristylar temples, or rotundas, whose cella was enclosed by an external colonnade, were not uncommon. Of this kind is the temple of the Sibyl, or, as it is otherwise called, that of Vesta, at Tivoli, an edifice of singular beauty, and highly interesting as a very peculiar and unique example of the Corinthian order. Edifices of this kind were covered with hemispherical domes, or with smaller sections of a sphere, which consequently did not show themselves much externally, as they were raised only over the *cella*, and therefore the lower part was concealed by the colonnade projecting around it. The dome of the Pantheon is hemispherical within, but is of very low proportions and flattened form without, for its spring commences at about the level of the first or lower cornice of the exterior cylinder, and is further reduced by the base of the outer portion of the dome being expanded and formed into separate cylindrical courses or gradini.

Polygonal forms of plan were sometimes employed, of which there is an instance in what is called the temple of Minerva Medica at Rome, which is circular on the exterior, but internally decagonal, with nine of its sides occupied by as many recesses, and the other by the doorway—a remarkable peculiarity, it being very unusual to enclose a polygon within a cylindrical structure, although not the contrary, nor to erect a cylinder upon a square or polygonal basement. Octagonal plans were by no means uncommon: such form was frequently made use of for the saloons of public baths; and there is an instance of an octagonal temple, supposed to have been dedicated to Jupiter, in one of the courts of Diocletian's palace at Spalatro. Of hexagonal structures we are acquainted with no example, but a court with six sides occurs in the remains of the temple of Baalbec, not however a regular hexagon, but of elongated figure, two of the sides being 110, and the remaining four 88 feet each. In the later periods of Roman architecture, circular and polygonal structures became more frequent, and those of the first-mentioned kind deviated considerably from the original simple rotundas and circular temples. An inner peristyle of columns was introduced so as to make a spacious circular or ring-shaped ambulatory around the centre, which was much loftier than the colonnade, being covered by a dome raised upon a cylindrical wall over the columns. What is now called San Stefano Rotunda, at Rome, supposed by some to have been originally a temple dedicated first to Faunus, and afterwards to the emperor Claudius, and by others to have been a public market, is a structure planned according to the arrangement just mentioned, with a circular Ionic colonnade of twenty columns and two piers. The church of Santa Costanza, supposed to have been erected by Constantine as a baptistery, and afterwards converted by him into a funeral chapel to his daughter Constantia, is a remarkable example, owing to the columns being not only coupled, but unusually disposed, and to there being arches springing from their entablature, that is, there are twenty-four columns (with composite capitals) placed in pairs, on the radii of the plan, or one behind the other, forming twelve inter-columns and as many arches; and as far as the mere arrangement goes, this interior is strikingly picturesque.

The circular form was a favourite one with the Romans for their sepulchral structures of a more pretending class than ordinary: following in this the example of the Etruscans. It will be sufficient here merely to mention those in honour of Augustus and Hadrian, an account of which has been given under MAUSOLEUM. The tomb of Cæcilia Metella is a low cylinder, the height being only 62 feet, while the diameter is 90; and it may be considered as nearly solid, the chamber or cella being no more than 19 feet in diameter. This cylindrical mass is raised upon a square substructure; which combination of the two forms is productive of agreeable contrast; and it was accordingly frequently resorted to. The tomb of Plautius Sylvanus near Tivoli consists also of a short cylindrical superstructure on a square basement, but is otherwise of peculiar design, one side of that stereobate being carried up so as to form a sort of low screen or frontispiece, decorated with six half-columns, and five upright tablets with inscriptions, between them. The tomb of Munatius Plancus, at Gaeta, is a simple circular structure, of low proportions, the height not exceeding the diameter, and therefore hardly to be called a tower, notwithstanding that it is now popularly called Roland's or Orlando's Tower. Of quite different character and design from any of the preceding, is the ancient Roman sepulchral monument at St. Remi, which consists of three stages; the first a square stereobate raised on gradini, and entirely covered on each side with sculptures in relief; the next is also square with an attached fluted Corinthian angle, and an open arch on each side; and the uppermost is a Corinthian rotunda, forming an open or monopteral temple (that is, without any cella), the centre of which is occupied by two statues.

As instances of other combinations, we may refer to what is called the Tomb of Virgil, near Naples, consisting of a square substructure surmounted by a conical one; to the Roman monument at Constantina, in Africa, conjectured to have been a cenotaph in honour of Constantine, the lower portion of which is a cylindrical structure surrounded by a peristyle of twenty-four Doric columns, and carried up as a lofty cone, in receding courses or gradini, leaving at its summit a platform for an equestrian statue.

These notices may serve to convey some idea of the variety aimed at by the Romans in the distribution of the plans and general masses of their edifices, independently of decoration. Their Thermæ, or public baths, a class of structures remarkable for their vast extent and magnificence, are most interesting studies of combinations of plan, as they were not merely baths, but places of public resort and amusement, and consisted of an assemblage of courts, porticos, libraries, and spacious saloons and galleries, most of which presented some peculiarity of form and distribution. [BATHS.] If therefore we estimate Roman architecture by the manifold resources which it opened to the art, rather than by its debasement of what it borrowed from that of Greece, we shall find much in it both to admire and to imitate, as well as to censure and to avoid. Its Greek rival has nothing that will bear a parallel with it in this respect. Judging from its remains, we can see little in it that answers to the title of interior architecture; whereas some of the Roman temples were striking on account both of the size and the magnificence of their interiors. That of the Pantheon has been already referred to; a very different example is the Temple of Peace, erected by Vespasian. What was its external design is now altogether doubtful, as only the ruins remain, but its interior is very remarkable, the plan being divided in its breadth into three nearly equal portions, the centre one of which formed a spacious nave, terminating in a large semicircular tribune, or apsis, covered by a semidome. This nave was disposed in three compartments, presenting as many arches of exceedingly wide proportions, opening into as many divisions of the lateral portions of the plan, which did not constitute continuous aisles along the nave, but small chapels or recesses. Of these the centre one on each side terminated, like the nave, in a semicircular tribune, of the same dimensions as that apsis, so as to form a transept, and give the whole a marked cruciform appearance. The side divisions were covered by semicircular vaults, concentric with the arches opening into the nave; and this latter had a vaulted roof, in three groins or compartments, the ribs of which sprung from eight Corinthian columns, placed against the piers of the arches. Besides other peculiarities, we have here an instance of the effect resulting from the application of the semicircular form to plans in interiors, and of further varieties of design arising out of it, for the semidomes of the tribunes exhibit a rich specimen of coffering, being composed of octagons and squares.

The temple of Venus and Roma, built by Hadrian in the Roman Forum, would seem from recent excavations to have been one of the most splendid edifices in the city. According to the plan of M. Caristie, the temple stood in the centre of a quadrilateral enclosure, or peribolus, measuring 525 by 318 feet, and was enclosed by double colonnades of the Corinthian order, consisting altogether of 264 columns. The temple itself was of the same order, upon a considerably larger scale, and its dimensions about 350 by 166 feet. It was consequently large in proportion to the area within which it stood; and when viewed in combination with the extended files of columns around it, must have produced a powerful effect,—one in which harmony and regularity were blended with contrast. The interior, judging from the indications afforded by the ruins, must have been equally splendid and picturesque in character.

The Romans seem to have affected the practice of grouping buildings together as features in one general symmetrical plan. Their temples and basilicas were frequently placed, as the principal architectural objects, at the extremity of a forum, or other regular area enclosed with colonnades. The temple of Nerva stood at one end of, and partly projected into an enclosure (measuring about 360 by 160 feet), the entrance end of which had five open arches, and the sides were formed by screen walls, decorated with Corinthian pilasters, and columns immediately before them, over which the entablature formed breaks. Of Trajan's forum, which was surrounded not only by colonnades, but various stately edifices, nothing now remains except the celebrated triumphal column that occupied its centre, and which, so placed as a principal object, must have heightened the splendour of the whole. Like that of Nerva, the temple of Antoninus and Faustina was placed at one end of a court of moderate dimensions, whose sides were adorned with coupled columns placed immediately against the walls; and only the portico part of the temple (a Corinthian hexastyle, triprostyle) [PORTICO] advanced into the enclosed area in front. The forum of Caracalla was nearly a square, entirely surrounded by arcades, presenting thirteen arches on each of the longer and eleven on each of the shorter sides. In the centre was a Corinthian temple very similar in plan to the Pantheon, with an hexastyle, triprostyle portico in front, and remarkable for having inner columns behind the second from each angle, so that there was a double range of them at each end, and the central space within the portico was a perfect square equal to three intercolumns.

The mention we have incidentally made in regard to these temples may not improperly be followed by some additional remarks upon Roman edifices of that class. Unlike those of Greece, peripteral temples were of comparatively rare occurrence among the Romans; they were mostly prostyle, the portico being attached only in continuation of the cella, whose walls formed the flanks of the building, though the order of the portico was frequently continued along them either in half-columns or pilasters. Such is the plan of that celebrated one at Nismes, known by the name of the Maison Quarrée, which is a Corinthian hexastyle, pseudo-peripteral, the cella being ornamented with attached columns, thereby making ten intercolumns on each flank, three of which are open, or belong to the portico, which latter is accordingly *triprostyle*. The Corinthian temple at Assisi was similar in plan, except that it was not pseudo-peripteral, the sides of the cella being plain. That of Fortuna Virilis at Rome was an Ionic tetrastyle, diprostyle, and pseudo-peripteral. Besides contributing to variety, temples of this kind possess a certain variety of effect in themselves, owing to the depth of the portico, and the contrast between that part and the cella. The portico announced itself more decidedly as the façade *par excellence;* particularly as such temples were generally raised upon a stereobate continued as pedestals to enclose the steps leading up to them in front, and which sometimes, as in the temple of Nerva, and that of Antoninus and Faustina, projected very considerably.

As our object is rather to direct attention to the modes of composition affected by the Romans and the elements of their style, than to describe their chief architectural monuments, either historically or according to their respective classes and destination, we proceed now to consider some of the individual peculiarities and features belonging to their buildings. In the application of sculpture, particularly of statues, they were prodigal; but they employed the latter chiefly as architectural accessories, frequently placing them over columns, or on the summits of their edifices as acroteria to pediments, by way of giving variety to the outline of their buildings, and also of indicating at first sight their particular appropriation—a practice almost unknown to the Greeks, there being only one instance of it. The abundant use of statues led to the adoption of the niche—a feature unknown in Greek architecture—as a convenient mode of inserting them within the surface of walls, and thereby decorating them; at the same time space was gained in interiors, where, if otherwise placed, they would have taken up room. Niches frequently occur in Roman temples and baths. [NICHE.]

These various applications of curvilinear forms, both in plan and elevation, undoubtedly furnished Roman architecture with resources unknown to that of Greece. Nor can it be denied that the arch itself is a very beautiful feature, although it was employed by the Romans to such excess as rather to occasion monotony than to contribute to variety of design; the amphitheatres and similar works of the Romans consisting only of continuous tiers of arches, which constituted their more strongly marked features, the columns placed against their tiers being merely ornamental accessories, and comparatively of little effect, and even that not of the very best kind. There was one class of structures however, which, though consisting uniformly of arches and piers alone, were eminently impressive and picturesque, namely, the Roman aqueducts, works of extraordinary grandeur, if estimated by their prodigious extent, and the colossal massiveness of their construction, but not otherwise entitled to be termed magnificent, their architecture being in the plainest and severest style. In these there were sometimes two or even more tiers of arches, at others only a single one, as in that at Metz on the Moselle, which has exceedingly lofty arches, or, to speak more correctly, arches on exceedingly lofty piers, divided by offsets into three stages, the effect of which is no less advantageous than it is uncommon.

Another practice was eventually adopted, by means of which the arch and column became amalgamated as integral parts of the same ordinance, namely, that of supporting arches upon columns, making them spring either directly from their capitals or from an entablature-shaped block over them. This practice is commonly condemned as barbarous, but in our opinion somewhat too hastily, and with more of prejudice than of fair examination. That it was introduced during the decline of the art, and that it was an innovation subversive of former principles, is not to be denied. Yet if it must be reprobated, it ought to be so for its own demerits, not as an innovation: for all invention is such. It appears a very poor argument against it, to say that columns were originally designed to support horizontal architraves: we do not see how that circumstance, of necessity, renders every other application inadmissible. Where columns are employed to support, it certainly cannot be alleged that they are idle unmeaning expletives; nor that they are mutilated by being apparently partly embedded in the wall behind them. One very great advantage attending the combination of the arch with the column as its support, is that it allows the openings to be considerably wider than they otherwise could be, because such intervals as would produce a poor and straggling effect in a colonnade, become well proportioned and agreeable when spanned by arches.

Of the two Grecian orders, the Roman specimens usually referred to, namely, the Doric of the theatre of Marcellus, and the Ionic of that building and the temple of Fortuna Virilis, are exceedingly poor and meagre, spiritless and tasteless; while the Ionic of the temple of Concord may be pronounced detestable. In this last example the volutes of the capitals are turned diagonally, a mode afterwards adopted by Scamozzi for that order, and also practised in what is called the Composite. Even when comparatively pleasing in its contours, the Roman Ionic capital is poor and devoid of expression, in consequence of the smallness of the volutes, which is such that they almost cease to be characteristic features of the order. To this defect may be added the meagreness arising from the few revolutions made by the spirals, and the omission of intermediate ones; and also the harshness occasioned by the great projection of the ovalo, the narrowness of the face of the capital above it, and by that part forming a straight line, instead of the gracefully-flowing festoon-hem which unites the volutes together in all the Athenian specimens of the order. Numerous studies of both voluted and foliaged capitals may be seen in Piranesi's 'Magnificenza de' Romani;' and the variety of composition displayed in the latter very greatly exceeds what would be imagined by those who are acquainted only with what are referred to as standard examples of that order. This last may in fact be emphatically denominated the Roman order, although such distinctive title is usually applied to what is otherwise called the Composite, but which is only a variety of the foliage-capitalled class, and by no means the most striking as such, there being instances of compound capitals, in which griffins, eagles, human figures, or masks, are introduced above the foliage; consequently, if the voluted variety is to be received as a separate order, each of the others is quite as much entitled to the same distinction. How far the ordinary Corinthian capital differs from that in which the small volutes, or caulicoli, at the angles of the abacus are developed, and enlarged to the size of those of the Roman Ionic capital, may at once be seen by referring to COLUMN, col. 33, where a half of each example is placed in juxtaposition; and at col. 45 will be found a similar comparison between the capitals of the Tivoli Corinthian and that of the monument of Lysicrates. The contrast presented by the two last is striking enough, there being no similarity of character, but merely such degree of resemblance as serves to make the differences the more obvious. And if that Tivoli example be compared with the one shown in the other cut, and which may be received as an average sample of the order, it will be tolerably evident, even from such comparison alone, that the foliaged capital was treated by the Romans in a variety of modes and in a free artistical spirit. Neither are such distinctions confined to the capitals alone, for different examples present equal diversity in their entablatures and cornices. That of the Tivoli temple is remarkable throughout; and has such a peculiar character stamped upon it, that it almost deserves to be considered a separate order—certainly much more so than the Composite. Among other examples, that of the three columns of the temple of Jupiter Stator is the richest and most elegant in its capital, and is beautifully composed throughout. The Romans in fact bestowed as great diversity of character and expression upon this order, as the Greeks had done upon their Doric and Ionic.

For information respecting Roman buildings adapted to particular purposes, the reader is referred to the articles ARCH, TRIUMPHAL; AMPHITHEATRE; AQUEDUCT; BASILICA; BATHS; FORUM; MAUSOLEUM; TEMPLE; THEATRE, &c.

ROMAN CATHOLICS. [CATHOLIC CHURCH; RECUSANTS.]

ROMAN CATHOLICS AND JEWS. By the act 9 & 10 Vict., cap. 59, passed August 18, 1846, intituled "An Act to relieve her Majesty's subjects from certain penalties and liabilities in regard to religious opinions;" all the previous Acts and parts of Acts imposing disabilities on the professors of the Roman Catholic or Jewish religions were repealed, of which a portion, as far as Roman Catholics were concerned, had been indirectly removed by the Roman Catholic Relief Act. On August 1, 1851, however, was passed an Act 14 & 15 Vict., cap. 60, "To prevent the assumption of certain Ecclesiastical Titles in respect of places in the United Kingdom," by which a penalty of 100*l.* was imposed on any one assuming the title of archbishop, bishop, or dean of any province, place, or district in the United Kingdom; and which declared any such creation by the see of Rome to be illegal and void. It also made illegal and void, punishable with the like pecuniary penalty, the publication of any bull, brief, rescript, letters apostolical, or any other instrument or writing constituting such province or district, whether such district be or be not the see or diocese, or deanery, of the established church. On July 23, 1858, likewise was passed the 21 & 22 Vict., cap. 19, intituled "An Act to provide for the relief of her Majesty's subjects professing the Jewish religion," by which Jews on taking the oath before sitting in parliament, may be relieved, by a resolution of the house, from making the declaration, "I make this declaration on the true faith of a Christian;" and these words are to be omitted in every other oath, except on making presentation to an ecclesiastical benefice. Jews are also declared incapable of holding the office of lord-lieutenant of Ireland, lord chancellor of Great Britain or Ireland, or high commissioner of the general assembly of the church of Scotland. The right of presentations to ecclesiastical benefices, vested in Jews, is devolved in the archbishop of Canterbury, nor are Jews to advise in the disposal of such matters; a contravention of these provisions to be deemed a misdemeanour, and a conviction entails a disability of serving the crown in any office, civil or military, whatever.

ROMAN LAW. The historical origin of the Roman law is unknown, and its fundamental principles, some of which even survived the legislation of Justinian, are older than the oldest records of Italian history. The foundation of the strict rules of the Roman law as to familia, agnatio, marriage, testaments, succession to intestates, and ownership, was no doubt custom, which, being recognised by the sovereign power, became law. As in many other states of antiquity, the connection of the civil with the ecclesiastical or sacred law was most intimate; or rather, we may consider the law of religion as originally comprehending all other law, and its interpretation as belonging to the priests and the king exclusively. There was, however, direct legislation even in the period of the kings. These laws, which are mentioned under the name of Leges Regiæ, were proposed by the king, with the approbation of the senate, and confirmed by the populus in the Comitia Curiata, and, after the constitution of Servius Tullius, in the Comitia Centuriata. That there were remains of this ancient legislation existing even in the Imperial period, is certain, as appears from the notice of the Jus Civile Papirianum or Papisianum, which the Pontifex Maximus Papirius is said to have compiled from these sources, about or immediately after the expulsion of Tarquinius Superbus ('Dig.,' i., tit. 2), and from the distinct references to these Leges made by late writers. Still there is great uncertainty as to the exact date of the compilation of Papirius, and its real character. Even his name is not quite certain, as he is variously called Caius, Sextus, and Publius. (Dion. Hal., iii. 36; 'Dig.,' i., tit. 2.)

But the earliest legislation of which we have any important remains is the compilation of the code called the Twelve Tables. The original bronze tables indeed are said to have perished in the conflagration of the city after its capture by the Gauls, but they were satisfactorily restored from copies and from memory, for no ancient writer who cites them ever expresses a doubt as to the genuineness of their contents. It is the tradition that a commission was sent to Athens and the Greek states of Italy, for the purpose of examining into and collecting what was most useful in their codes; and it is also said that Hermodorus of Ephesus, then an exile in Rome, gave his assistance in the compilation of the code. There is nothing improbable in this story, and yet it is undeniable that the laws of the Tables were based on Roman and not on Greek or Athenian law. Their object was to confirm and define perhaps rather than to enlarge or alter the Roman law; and it is probable that the laws of Solon and those of other Greek states, if they had any effect on the legislation of the Decemviri, served rather as models of form than as sources of positive rules.

Ten tables were completed and made public by the Decemviri, in B.C. 451, and in the following year two other tables were added. This compilation is quoted by the ancient writers by various titles: Lex XII. Tabularum, Leges XII., sometimes XII. simply (Cic., 'Legg.,' ii. 23), Lex Decemviralis, and others. The rules contained in these tables long continued to be the foundation of Roman law, and they were never formally repealed. The laws themselves were considered as a text book, and they were commented on by the jurists as late as the age of the Antonines, when Gaius wrote a commentary on them in six books ('Ad Legem XII. Tabularum'). The actions of the old Roman law, called Legitimæ, or Legis Actiones, were founded on the provisions of the Twelve Tables, and the demand of the complainant could only be made in the precise terms which were used in the Tables. (Gaius, iv. 11.) The rights of action were consequently very limited, and they were only subsequently extended by the edicts of the prætors. The brevity and obscurity of this ancient legislation rendered interpretation necessary in order to give the laws any application; and both the interpretation of the laws and the framing of the proper forms of action belonged to the College of Pontifices, who yearly appointed a member of their own body to decide in all doubtful cases. The civil law was thus still inseparably connected with that of religion (Jus Pontificium), and its interpretation and the knowledge of the forms of procedure were still the exclusive possession of the patricians.

The scanty fragments of the Twelve Tables hardly enable us to form a judgment of their character or a proper estimate of the commendation bestowed on them by Cicero ('De Or.,' i. 43). It seems to have been the object of the compilers to make a complete set of rules both as to religious and civil matters; and they did not confine themselves to what the Romans called private law, but they comprised also public law. ('Fons publici privatique juris,' Liv., iii. 34.) They contained provisions as to testaments, successions to intestates, the care of persons of unsound mind, theft, homicide, interments, &c.

They also comprised enactments which affected a man's status, as, for instance, the law contained in one of the two last Tables, which did not allow to a marriage contracted between a patrician and a plebeian the character of a legal Roman marriage, or, in other words, declared that between patricians and plebeians there could be no Connubium. Though great changes were made in the Jus Publicum by the various enactments which gave to the plebeians the same rights as the patricians, and by those which concerned public administration, the fundamental principles of the Jus Privatum, which were contained in the Tables, remained unchanged, and are referred to by jurists as late as the time of Ulpian.

The old Leges Regiæ, which were collected into one body by Papirius, were commented on by Granius Flaccus in the time of Julius Cæsar ('Dig.,' 50, tit. 16, s. 144), and thus they were probably preserved. The fragments of these laws have been often collected, but the best essay upon them is by Dirksen, 'Versuchen zur Kritik und Auslegung der Quellen des Römischen Rechts,' Leipzig, 1823. The fragments of the Twelve Tables also have been often collected. The best work on the subject is that by James Godefroy (Jac. Gothofredus), which, with the more recent work of Dirksen, 'Uebersicht der bisherigen Versuche zur Kritik und Herstellung des Textes der Zwölf-Tafel-Fragmente,' Leipzig, 1824, seems to have exhausted the subject.

For about one hundred years after the legislation of the Decemviri, the patricians retained their exclusive possession of the forms of procedure. Appius Claudius Cæcus drew up a book of the forms of actions, which it is said that his clerk, Cnæus Flavius, stole and published; the fact of the theft may be doubted, though that of the publication of the forms of procedure, and of a list of the Dies Fasti and Nefasti, rests on sufficient evidence. The book thus made public by Flavius was called Jus Civile Flavianum; but like that of Papirius it was only a compilation. The publication of these forms must have had a great effect on the practice of the law: it was in reality equivalent to an extension of the privileges of the plebeians. Subsequently Sextus Ælius published another work, called 'Jus Ælianum,' which was more complete than that of Flavius. This work, which was extant in the time of Pomponius ('Dig.,' i., tit. 2, s. 2, § 39), was also called 'Tripertita,' from the circumstance of its containing the laws of the Twelve Tables, a commentary upon them (interpretatio), and the Legis Actiones. This work of Ælius appears to have been considered in later times as one of the chief sources of the civil law (veluti cunabula juris); and he received from his contemporary Ennius the name of "wise":—

"Egregie Cordatus homo Caius Ælius Sextus."

Sextus Ælius was Curule Ædile, B.C. 200, and Consul, B.C. 198.

In the Republican period new laws (leges) were enacted both in the Comitia Centuriata and in the Comitia Tributa. The Leges Curiatæ, which were enacted by the curiæ, were limited to cases of adrogation and the conferring of the imperium. The Comitia Centuriata were made independent of the senate by the Lex Publilia (Liv., viii. 12), which declared that the leges passed in these Comitia should not require the confirmation of the senate. The leges passed in the Comitia Tributa were properly called Leges Tributæ or Plebiscita, and originally they were merely proposals for a law which were laid before the senate and confirmed by the curiæ. But the Lex Publilia (B.C. 336), and subsequently the Lex Hortensia (B.C. 286), gave to the Plebiscita the full force of leges without the consent of the senate (Liv., viii. 12; Gaius, i. 3; Gell., xv. 27); and a Plebiscitum was accordingly sometimes called a lex. The leges generally took their name from the gentile name of the magistrate who proposed them (rogavit), or, if he was a consul, from the name of both consuls, as Lex Ælia or Ælia Sentia, Papia or Papia Poppæa. If the proposer of the law was a dictator, prætor, or tribune, the Lex, or Plebiscitum, as the case might be, took its name from the proposer only, as Lex Hortensia. Sometimes the object of the lex was indicated by a descriptive term, as Lex Cincia de donis et muneribus.

The Senatus Consulta also formed a source of law under the Republic. That a senatus consultum in the time of Gaius (i. 4) should have the force of law (vicem legis optinet) may be easily admitted; but Gaius in this passage appears to be referring not only to such senatus consulta as had been passed under the empire, but to the senatus consulta generally as a source of law. It appears that the senate gradually came to be considered as the representative of the curiæ, and that its consulta, in many matters relating to administration, the care of religion, the ærarium, and the administration of the provinces, had the full effect of laws. It does not seem as if the Romans themselves had a very clear notion of the way in which the senate came to exercise the power of legislation; but they imagined that it arose of necessity with the increasing population of the state and the increase of public business. The senate thus became an active administrating body, and, as an easy consequence, that which it enacted (constituit) was observed, and this new source of law was termed Senatus Consultum. ('Dig.,' i., tit. 2.) It seems probable that the senate began to exercise the power of making senatus consulta after the passing of the Hortensia Lex, though it is not pretended that the Hortensia Lex, or any other Lex, gave this power to the senate. No senatus consulta are recorded as designated by the names of magistrates till the time of Augustus, a circumstance which seems to show that, whatever binding authority senatus consulta might have acquired under the Republic, they were not then viewed as laws properly so called, or as having the full effect of leges. But from the time of Augustus the titles of senatus consulta frequently occur; their names, like those of the leges, were derived from the consuls, as S. C. Velleianum, Pegasianum, Trebellianum, &c., or of the emperor who proposed them, as S. C. Claudianum, Neronianum, &c.; or they were said to be made "auctore Principe," or "ex auctoritate Principis." The expression applied to the senate so enacting was "censere." (Gaius, i. 17.) Special consulta were sometimes passed for the purpose of explaining or rendering effectual previous leges.

A new source of law was supplied by the Edicta of those magistrates who had the Jus Edicendi, but mainly by the prætors, the prætor urbanus and the prætor peregrinus. The edicts of the prætor urbanus were the most important. The body of law which was formed by the Edicta is accordingly sometimes called Jus Prætorium, which term however might be limited to the Edicta of the prætors, as opposed to those of the curule ædiles, the tribunes, censors, and pontifices. The name Jus Honorarium, as opposed to Jus Civile, comprehends the whole body of edictal law; and the name Honorarium was given to it, apparently because the Jus Edicendi was exercised only by those magistrates who had the Honores. Jus Civile, in its larger sense, comprehended all the law of any given nation; but the Jus Civile Romanorum, as opposed to the Honorarium, consisted of Leges, Plebiscita, Senatus Consulta, to which, under the empire, were added the Decreta Principum and the Auctoritas Prudentium. The Honorarium Jus was introduced for the purpose of aiding, supplying, and correcting the defects of the Jus Civile Romanorum in its limited sense. ('Dig.,' i., tit. i., s. 7.)

The historical origin of the edictal power is not known, but in the time of Cicero it had been so long exercised, and the Edicta had been so far formed into a regular system, that the study of the edictal law was a main part of the systematic study of the Roman law, and had taken the place of the Twelve Tables as an elementary branch of instruction. (Cic., 'Legg.,' ii. 4, 23; i. 5.) Servius Sulpicius, a distinguished jurist and a friend of Cicero, wrote two small books on the Edict, which were followed by a work of Ofilius, also on the Edict. Though the history of the edictal law, as already observed, cannot be traced, it thus appears that it had assumed a systematic form in the time of Cicero.

An Edictum was a rule promulgated by a magistratus when he entered on his office. It was committed to writing and put up in a public place. Its object was to declare by what rules the prætor would be governed in the administration of justice during the year of his office; and hence the Edictum was sometimes called Perpetuum or Annua Lex. An Edictum Repentinum applied only to the particular occasion on which it was made. All offices being annual, the rules of one magistratus were not binding on his successor, but his successor might adopt them into his own Edictum, and such adopted Edictum then became an Edictum Tralatitium. In this way numerous Edicta were adopted by one magistratus from the Edicta of his predecessors, and thus gradually a body of rules was formed and established, which experience had proved to be useful. Those Edicta which were of great importance are often referred to under the name of the magistratus who promulgated them, as the Edictum Carbonianum and others.

The general character of the Edict has been already stated. It is described in other words as "viva vox juris civilis," as a mode by which the rigid rules of the civil law were altered and extended to suit the altered circumstances of the times. The changes introduced by positive enactments into the Jus Privatum of the Roman law seem to have been very unimportant. It was not consistent with Roman notions to alter or change fundamental principles, and most of the legislation of the republican period had reference to the disputes between the two estates of the patricians and plebeians, and to other parts of the Jus Publicum. Accordingly it was left to the magistratus gradually to introduce the necessary changes into the Jus Privatum; but the process of doing this was in strict conformity to the principles of the old law. The Edict did not affect to make new law, but to adopt as law what custom had sanctioned, provided it was not against the Jus Civile; to give an action when a *bonâ fide* right existed, if the old law gave none; to protect a man in *bonâ fide* possession of property, without affecting to give him ownership, which the law alone could give him by virtue of usucapion; to aid parties by fictions, which however were always of such a kind that the thing which the fiction supposed, was that which would have given a strictly legal right. A great part of the efficacy of the Edict consisted in extending the remedies by action; and after the abolition of the Legis Actiones (with the exception of the Actio Damni Infecti, and of matters which belonged to the cognisance of the Centumviri) by the Lex Æbutia and two Leges Juliæ, the mode of proceeding in actions was settled by the formulæ of the Edicta. Still even here it seems probable that the prætors followed the analogy of the Legis Actiones and framed their formulæ accordingly. The Actiones given by the Edict were named after their author, as Publiciana, &c. The commentators on the Edicts were numerous under the early emperors. Labeo wrote at least four books on the Edictum of the Prætor Urbanus. Cœlius Sabinus commented on the Edict of the Curule Ædiles. In the time of Hadrian, Salvius Julianus, who had himself been prætor, compiled a work on the Edict, which was called Edictum Perpetuum. Nothing is known of the detail of this work, but it appears probable that it was designed to be a systematic exhibition of the whole body of edictal law, and as such it must have had considerable influence on the subsequent condition of jurisprudence. At what time the Edicta ceased to be made by the magistratus is a disputed point. The edictal power certainly existed under the empire, and even after the compilation of the Edictum Perpetuum of Julianus, but it must have been comparatively little exercised, as the practice of making new laws by Senatus Consulta prevailed under the Cæsars after the time of Augustus, and the Imperial Constitutions are mentioned as one of the recognised sources of law in the time of the Antonines. (Gaius, i. 5.)

With the establishment of the Imperial Constitution begins a new epoch in the Roman law. The leges of Augustus and those of his predecessor had some influence on the Jus Privatum, though they did not affect the fundamental principles of the Roman law. A Lex Julia came into operation, B.C. 18, but it is better known as the Lex Julia et Papia Poppæa, owing to the circumstance of another lex of the same import, but less severe in its provisions, being passed as a kind of supplement to it in the consulship of M. Papius Mutilus and Q. Poppæus Secundus, A.D. 9. This law had for its object the encouragement of marriage, but it contained a great variety of provisions: it is not known whether it was passed at the Comitia Centuriata or Tributa. A Lex Julia de Adulteriis, which also contained a chapter on the dos, is of uncertain date, but was probably passed before the former Lex Julia came into operation. Several Leges Juliæ Judiciariæ are also mentioned, which related both to Judicia Publica and Privata, and some of which may probably belong to the time of the dictator Cæsar.

The development of the Roman law in the Imperial period was little affected by direct legislation. New laws were made by Senatus Consulta, and subsequently by the Constitutiones Principum; but that which gives to this period its striking characteristic is the effect produced by the Responsa and the writings of the Roman jurists.

So long as the law of religion or the Jus Pontificium was blended with the Jus Civile, and the knowledge of both was confined to the patricians, jurisprudence was not a profession. But with the gradual separation of the Jus Civile and Pontificium, which was partly owing to the political changes by which the estate of the plebeians was put on a level with that of the patricians, there arose a class of persons who are designated as Jurisperiti, Jurisconsulti, Prudentes, and by other equivalent names. Of these jurisconsulti the earliest on record is Tiberius Coruncanius, a plebeian pontifex maximus, and consul B.C. 281: he is said to have been the first who professed to expound the law to any person who wanted his assistance (publice profiteri); he left no writings, but many of his Responsa were recorded. Tiberius Coruncanius had a long series of successors who cultivated the law, and whose responsa and writings were acknowledged and received as a part of the Jus Civile. The opinions of the jurisconsulti, whether given upon questions referred to them at their own houses, or with reference to matters in litigation, were accepted as the safest rule by which a judex or an arbiter could be guided. Accordingly, the mode of proceeding, as it is described by Pomponius, is perfectly simple; the judices in difficult cases took the opinion of the jurisconsulti, who gave it either orally or in writing. Augustus, it is said, gave the responsa of the jurists a different character. Before his time, their responsa, as such, could have no binding force, and they only indirectly obtained the character of law by being adopted by those who were empowered to pronounce a sentence. Augustus gave to certain jurists the respondendi jus, and declared that they should give their responsa "ex ejus auctoritate." In the time of Gaius (i., 7) the Responsa Prudentium had become a recognised source of law; but he observes that the responsa of those only were to be so considered who had received permission to make law (jura condere): and he adds that if they all agreed, their opinion was to be considered as law; if they disagreed, the judex might follow which opinion he pleased. The matter is thus left in some obscurity, and, for want of more precise information, we can only conjecture what was the precise way in which these licensed jurists under the empire were empowered to declare the law. It is however clear, both from the nature of the case and the statement of Gaius, that their functions were limited to exposition, or to the declaration of what was law in a given case, and that they had no power to make new rules of law as such; further, the licensed jurists must have formed a body or college, for otherwise it is not possible to conceive how the opinions of the majority could be ascertained on any given occasion.

The commencement of a more systematic exposition of law under the empire is indicated by the fact of the existence of two distinct sects or schools (scholæ) of jurists. These schools originated under Augustus, and the heads of each were respectively two distinguished jurists, Antisteus Labeo and Ateius Capito. But the schools took their names from other jurists. The followers of Capito's school, called Sabiniani, derived their name from Massurius Sabinus, a pupil of Capito, who lived under Tiberius and as late as the time of Nero: sometimes they were called Cassiani, from C. Cassius Longinus, another distinguished pupil of Capito. The other school was called Proculiani, from Proculus, a follower of Labeo. If we may take the authority of Pomponius, the characteristic difference of the two schools was this: Capito adhered to what was transmitted,—that is, he looked out for positive rules sanctioned by time; Labeo had more learning and a greater variety of knowledge, and accordingly he was ready to make innovations, for he had more confidence in himself; in other words, he was a philosophical more than an historical jurist. Gaius, who was himself a Sabinian, often refers to discrepancy of opinion between the two schools; but it is not easy to collect from the instances which he mentions what ought to be considered as their characteristic differences.

The jurisprudentes were not only authorised expounders of law, but they were most voluminous writers. Massurius Sabinus wrote three books Juris Civilis, which formed the model of subsequent writers. The commentators on the Edict were also very numerous, and among them are the names of Pomponius, Gaius, Ulpian, and Paulus. Gaius wrote an elementary work, which furnished the model of the Institutes of Justinian. Commentaries were also written on various Leges, and on the Senatus Consulta of the Imperial period; and finally, the writings of the earlier jurists themselves were commented on by their successors. The long series of writers to whom the name of classical jurists has been given, ends, about the time of Alexander Severus, with Modestinus, who was a pupil of Ulpian. Some idea may be formed of the vast mass of their writings from the titles of their works as preserved in the 'Digest,' and from the 'Index Florentinus;' but with the exception of the fragments which were selected by the compilers of that work, this great mass of juristical literature is nearly lost. [Justinian, in Biog. Div.]

Among the sources of law in the Imperial period are the Imperial Constitutiones. A Constitutio Principis is defined by Gaius (i. 5) to be "that which the imperator has constituted by Decretum, Edictum, or Epistola; nor has it ever been doubted that such constitutio has the force of law." As the emperor ultimately possessed all the sovereign power, he became the sole source of law. Under Augustus some Leges were passed, as already observed; and under his successors there were numerous Senatus Consulta. In the time of the Antonines there were both Senatus Consulta and Imperial constitutions, and the latter are referred to by Gaius as being of equally binding force with Senatus Consulta. After the time of Gaius, Constitutiones became more common, and few Senatus Consulta were passed. The Decretum of the emperor was a decision made in a matter of dispute which came before him either originally or by way of appeal. The Edict, or Leges Edictales, were formed by analogy to the Edicta of the magistrates, and were in effect Leges. Rescriptum was a general term which comprehended Epistolæ and Subscriptiones. The Rescripta were the answers of the emperor, made either to public functionaries or to individuals who consulted him. Sometimes Constitutio and Rescriptum are used as equivalent. (Gaius, ii. 120, 121.) Decreta and Rescripta, being decisions in particular cases, could not by their form have the force of leges; though when the determination made in a particular case was capable of a general application, it gradually obtained the force of law.

With the decline of Roman jurisprudence began the period of compilations, or codes, as they were termed. The earliest were the Codex Gregorianus and Hermogenianus, which are only known from fragments. The Codex Gregorianus, so far as we know it, began with constitutions of Sept. Severus, and ended with those of Diocletian and Maximian. The Codex Hermogenianus, so far as it is known, contained constitutions also of Diocletian and Maximian, and perhaps some of a later date. Though these codes were mere private collections, they apparently came to be considered as authority, and the codes of Theodosius and Justinian were formed on their model.

The code of Theodosius was compiled under the authority of Theodosius II., emperor of the East. It was promulgated as law in the Eastern Empire, A.D. 438; and in the same year it was confirmed as law in the Western Empire by Valentinian III. and the Roman senate. This code consists of sixteen books, the greater part of which, as well as of the Novellæ, subsequently promulgated by Theodosius II., are extant in their original form. The commission who compiled it were instructed to collect all the Edicta and Leges Generales from the time of Constantine, and to follow the Codex Gregorianus and Hermogenianus as their model. Though the arrangement of the subsequent code of Justinian differs considerably from that of Theodosius, it is clear from a comparison of them that the compilers of Justinian's code were greatly aided by that of his imperial predecessor. The valuable edition of the Theodosian Code, by J. Gothofredus (6 vols. fol., Lugd., 1665), re-edited by Ritter, Leipzig, 1736–1745, contains the first five books and the beginning of the sixth, only as they are epitomised in the Breviarium; and this is also the case with the edition of the 'Jus Civile Antejustinianeum,' published at Berlin in 1815. But recent discoveries have greatly contributed to improve the first five books. The most recent edition of the 'Jus Civile Antejustinianeum' is that of Bonn, 1835 and 1837.

The legislation of Justinian is treated of under Justinian's Legislation.

There are numerous works on the history of the Roman law, but it will be sufficient to mention a few of the more recent, as they contain references to all the earlier works: *Lehrbuch der Geschichte des Römischen Rechts*, by Hugo, of which there are numerous editions; *Geschichte des Römischen Privatrechts*, by Zimmern; *Geschichte des Römischen Rechts*, by F. Walter, 1840; and for the later history of the Roman law, *Geschichte des Römischen Rechts im Mittelalter*, by Savigny.

ROMAN SCHOOL OF PAINTING. [Painting.]

ROMANCE originally signified any composition in the romance language, or dialects which superseded the Latin after the fall of the Western Empire. [Romance Language.] As however, in course of time, the Trouveres of North France composed a number of poems containing fictitious narratives of war and love, and their lays became popular all over France and in the neighbouring countries, the name of romance was more particularly applied to all compositions, whether in verse or prose, in any language, which treated of marvellous or uncommon incidents, and the name has been retained to this day in several European languages to signify a fictitious narrative. The Italians and French call a novel "un romanzo," "un roman." But the French call an historical ballad "une romance," in the feminine gender. The distinction between romance and the modern novel is shown under Novel. The appellation romance in a narrower sense is applied to those compositions which refer to the ages of chivalry, either real or supposed. [Chivalry.]

The oldest romances in this latter sense appear to have been legendary stories concerning Arthur and the Knights of the Round Table, and they were of English origin; but the original narratives, if they ever existed in writing, which is doubtful, are lost. The earliest romantic legends which have come down to us are of the 12th century: Geoffrey of Monmouth's Latin Chronicle of England; Turpin's Latin Chronicle of France; Wace's 'Le Brut,' a metrical romance concerning the fabulous history of England, in Norman French; 'Le Roman du Rou,' by the same writer, concerning Rollo and his successors; and 'I Reali di Francia,' in Italian prose. To these may be added the Latin romance of Gualtieri, found in the Chronicle of La Novalesa, which relates to the wars of Attila; next in order of date comes Guido della Colonna's 'War of Troy,' and Mathew Paris's account of the Round Table. The 'Roman de la Rose' was written under St. Louis of France. At that time chivalry was established over all Europe, and the writers of romance introduced the customs and manners of chivalry into their narratives of events, real or supposed, long antecedent to the existence of chivalry.

The vast subject of romantic literature, in its general and more extended sense, may be divided into the following branches:—1, Romantic ballads and traditional songs, which appear to be the oldest form, and which have existed among most nations in their primitive state. The songs of the ancient bards, and those concerning Arminius, which are mentioned by Tacitus ('Annal.' ii. 88, and 'German.', 2); the German Niebelungen; the poems of Antar, and others before the æra of Mohammed; the song of Roland, mentioned by the chroniclers of Charlemagne; and the old Spanish romantic ballads, all belong to this class. M. de Tressan collected several fragments among the mountaineers of the Pyrenees, which seem to belong to Roland's 'Cantilena,' or war song. 2, The narrative romances of chivalry concerning the deeds of Arthur and the peers of the Round Table. 3, The romances concerning the supposed wars of Charlemagne against the Saracens. 4, The Spanish and Portuguese romances concerning the fabulous exploits of Amadis and Palmerin. 5, The classic romances concerning Jason, Hercules, Alexander, those heroes having been transformed into knights of chivalry. 6, The epic romances of the Italians in the 15th and 16th centuries. [Pulci, in Biog. Div.] 7, The spiritual or religious romances concerning the miracles of saints and the death of martyrs, such as the 'Contes dévots' of the French, the 'Golden Legend,' &c. 8, The pastoral romance, which Cervantes ridiculed, and which afterwards gave rise in the 17th century to the interminable and dull romances of La Calprenède, Madame de Scudery, and others, in which perfection of beauty and pure spiritual love are the chief ingredients. 9, The comic romances, which were written chiefly as parodies of the heroic and chivalrous romances. Such were those of Rabelais, Cervantes, Mendoza, and Scarron. 10, The political romances, such as Télémaque, Sethos, &c. 11, The supernatural romance, like the 'Castle of Otranto,' 'The Old English Baron;' in which may be included those of Mrs. Radcliffe, where a supernatural impression is given by inadequate natural causes. 12, Lastly comes the modern novel, which forms a distinct species, as it does not deal in the marvellous and supernatural, but represents men conformably to the manners of the age in which they lived.

ROMANCE LANGUAGE ('Langue Romane' or 'Romande,' in French) is the name given to a kind of bastard Latin, which came into common use in Western Europe after the fall of the Roman Empire, among the populations formerly subject to Rome, while the Northern conquerors, the Goths, Franks, Burgundians, Langobards, &c., spoke their own language or dialects, which are called by chroniclers of the times "lingua Teutonica," or "Teutisca." The conquered people were called by the general name of Romans, from whence came the name of the language, which was also called "vulgaris." In course of time however the conquerors adopted the language of the conquered, who being more instructed, furnished most of the priests and scholars of the age. But the language thus adopted by both the conquering and the conquered races, although essentially formed of Latin elements, differed according to the various localities and the greater or lesser degree of admixture of the northern people with the Roman population. For instance, king Dagobert in the 7th century published a statute, styled, "Lex Alamannorum," for the use of the German tribes who had crossed the Rhine, the language of which differs from that of the "Lex Ripuariorum," which the same king published for the use of the people situated between the Lower Rhine and the Mosa, who were mostly of old Roman extraction. The former employs the *ille* as an article before substantives, in imitation of the articles *sa* and *der* used by the Goths and Franks in their own language; but the Lex Ripuaria does not employ *ille* for the same purpose. In the old charters of Italy and Spain of the 8th and 9th centuries, we find *ille* and *ipse* employed likewise as articles, *ipsa ecclesia*, *illa alia*, *illas casas*, *illa strada*, *illo rio*, &c.; but these charters are not so old by a century or two as the Franco-Latin documents, in which those pronouns are introduced for a similar purpose. The oldest documents in the 'España Sagrada' in which the *ille* appears as an article is A.D. 775; and the oldest of those of Italy quoted by Muratori are of the years 713 and 736.

Of the various dialects thus formed, that of the south of France, called afterwards Langue d'Oc, became a refined language sooner than the others, and retained its superiority from the 10th to the 13th century, when the Italian, Portuguese, and Spanish languages assumed a regular grammatical and literary form, which they have retained; whilst the romance of the south of France has gradually fallen into disuse, having given way to the Northern French Langue d'Oil or d'Oui. The latter appears to have originally differed little from the Langue d'Oc, but it gradually changed its terminations, and assumed other peculiarities of form, which have been retained by the modern French. It is demonstrated by Raynouard that the inhabitants of Northern France in the 9th century spoke the same language as those of the south. The text of the oath taken at Strasburg in the year 842, by Louis, called the Germanic, before the French people, would alone be a sufficient proof of this. The text of this curious document is as follows:—"Pro Deo amur et pro Christian poplo, et nostro commun salvament, dist di en avant, in quant Deus savir et podir me dunat, si salvara jeo cist meon fradre Karlo, et in adjudha, et in cadhuna cosa, si cum om per dreit son fradre salvar dist, in o quid il mi altre si fazet, et ab Ludher nul plaid nunquam prindrai, qui meon vol cist meon fradre Karle in damno sit." (Roquefort, 'Glossaire de la Langue Romane,' Paris, 1808, Introduction.)

The gradual process by which the corrupt Latin spoken in the provinces of Western and Southern Europe in the 6th, 7th and 8th centuries was transformed into the Romance languages of the 9th and 10th centuries, is very clearly exhibited by Raynouard, in his 'Elémens de la Grammaire de la Langue Romane avant l'an 1000.' The Latin cases had become neglected or confused, and to supply their place the prepositions *de* served to denote the genitive and *ad* the dative. The next step was to cut off the final syllable of the noun, and so to make it indeclinable. Thus the accusative abbatem became abbat; majestatem, majestat; ardentem, ardent; amantem, amant; and so forth. The accusatives in *ionem* were reduced to *ion*, religionem, religion, &c. When the suppression of the Latin termination left two harsh-sounding consonants at the end of the word, a euphonic vowel was added, "arbitr-um," "ar-bitr-e." The pronouns *ille* and *ipse* had been used in the corrupt Latin as auxiliary to substantives: "Dono illas vineas quomodo ille rivulus currit;" "Illa medietate de ipsa porcione," &c. From *ille* so used originated the romance articles *el*, *lo*, *la*, and from *ipse* the demonstrative pronouns, *is*, *so* or *su*, and *sa*, which the Sardinian dialect has retained to this day as an article. These articles were declined with the prepositions *de* and *a*. "Ego Hugo della Roca;" "Fossatum de la vite;" "Villam nostram quæ vocatur al la Carbaria," &c. These and other examples taken from documents of the 9th century show the introduction of articles even in the written language which affected to preserve in some degree the Latin form; the change must have been more rapid and complete in the spoken or popular idiom. Other changes took place in the pronouns and the verbs, for which we refer to Raynouard's 'Elémens.' The use of the auxiliary verb *aver*, "habere," already existed in the Latin, in a certain form: "De Cæsare satis hoc tempore dictum habebo" (Cicero, 'Philip. V.' 28); "Si habes jam statutum quod tibi agendum putes" ('Epist. ad Famil.', iv. 2). The Latin also used the auxiliary "esse" in some tenses of the passive. The Romance language only made the use of these auxiliaries more general.

After A.D. 1000 the Romance language may be considered as having become duly formed, and the age of the Troubadours began. William, count of Poictiers, is one of the earliest whose works have been preserved. In the 12th century the institution of the Courts of Love was established. That century was the brilliant age of Romance poetry, and in the same Wace wrote in North or Norman French his 'Roman du Rou.' In the 13th century the war and massacre of the Albigenses, and the establishment of the Inquisition, frightened away many of the adepts of "la gaya ciencia;" and afterwards several other events, such as the accession of the house of Anjou or Provence to the throne of Naples, and the encroachments of the Northern French, contributed to the decline of the troubadour poetry, and at the same time of the Romance language. The Italian or Tuscan rose upon its decay. When Dante appeared, the decline had already begun, and it was completed during the first part of the 14th century. (Raynouard, 'Choix de Poesies Originales des Troubadours;' Professor Diez, 'Leben und Werke der Troubadours,' Zwickau, 1829.) In the 15th century king René made some attempts at reviving the poetry of the Langue d'Oc, but the race of the Troubadours was now extinct, and the only result of his endeavours was the collecting and compiling the lives of the old Troubadours by the monk of the isles of Hyeres, "Le Monge des Isles d'Or." In Eastern Spain also the Inquisition destroyed many manuscripts in the Limosin or Valencian language, as being suspected of containing heresy. In 1434 the library of the Marquis de Villena at Barcelona was burnt on suspicion of containing sorcery. (Ferrario, 'Storia ed Analisi degli antichi Romanzi,' &c.)

Various political and social circumstances had contributed to give to the Langue d'Oc that early refinement in an age of comparative ignorance and barbarism which is still a matter of surprise to philologists and historical inquirers. The provinces of Southern France had not, like Italy and the northern parts of France, been overrun by a succession of barbarians; they had not been exposed to the ravages of the Slavonians, the Huns, and the Danes. The Burgundians and the Visigoths, who had settled there nearly about the same time, were more civilised than the other German races; they amalgamated gradually and quietly with the old inhabitants, and they applied themselves to agricultural pursuits, which a fertile soil and a happy climate rendered pleasant and productive. The country suffered no subsequent invasion from the northern tribes, and the victory of Charles Martel in the plains of Tours arrested the advance of the Saracens from the west. Southern France was, it is true, subjugated by the Franks, who had occupied the countries north of the Loire, but the Franks had by that time formed themselves into a regular monarchy under Pepin and Charlemagne, and were no longer unruly barbarians. During the decline and imbecility of the latter princes of the Carlovingian dynasty, Southern France became a separate and independent state, of which duke Bozon, an active and vigorous man, became monarch, and the kingdom of Arles or Provence extended over the whole south of France. The descendants of Bozon retained their sovereignty for more than two hundred years; and when the male line ended in 1092, in the person of Count Gillibert, his states became the dowry of his daughters, of whom the elder, Douce, heiress of Provence, was married in the year 1112 to Raymond Berenger, count of Barcelona, and her sister Stephanie married the count of Toulouse. A treaty, concluded in 1125, between the counts of Barcelona and Toulouse, fixed the division of the states of Gillibert between them. Another powerful baron, the count of Poitiers, became duke of Aquitaine or Guyenne, which afterwards came by marriage into the possession of Henry II. of England. These three states, Barcelona, Toulouse, and Guienne included the whole country in which the Langue d'Oc was spoken. The union of Provence with Catalonia introduced into the former country a taste for poetry and chivalry, which was fostered in Spain by the Moors. The maritime towns of Catalonia and Provence carried on a lucrative trade all over the Mediterranean, and Catalonian armaments took an active part in the Eastern wars between the Greeks, the Normans, and the Saracens. All these circumstances contributed to refine the manners of the people as well as their language, and the singular institution of the Courts of Love gave a peculiar turn to their poetry. [TROUBADOURS.]

The Langue d'Oil, or Northern French, also called sometimes Norman French, having become the language of the court and capital of the kingdom of France, gradually encroached upon the Langue d'Oc, as the various provinces south of the Loire became incorporated with the monarchy. From the 13th century downwards, the edicts and ordinances of the French kings being issued in the Langue d'Oil, were forwarded, either in the original or translated into Latin, to the provinces of the south. The writers of Northern France, the Trouvères, refined their own language, and found encouragement at court, which was not extended to the writers in the Langue d'Oc. Ronsard, who was a native of the south, in his 'Abregé de l'Art Poétique,' complains of this : "Now that our France is all subject to one king, we are obliged, if we wish to attain honour or fame, to speak his language, else our works, however honourable and perfect, would be thought little of, or might perhaps be altogether despised and neglected." With the invention of printing, copies of the works in the Langue d'Oil were speedily multiplied, while those of the Troubadours remained mostly in manuscripts, confined to a few libraries. In the 16th century it was enacted that all public acts and deeds should be written in French. The Langue d'Oc, being thus restricted to the mere purposes of a domestic idiom, degenerated into various patois or dialects. Still there appeared, here and there, in the 17th and 18th centuries, several native poets who wrote with spirit and humour in their respective patois, such as Lesage, a Languedocian, whose burlesque and frequently licentious poems were published at Montpelier: 'Les Folies de le Sage,' 1650; Ader, 'Lou Gentilhomme Gascoun,' Toulouse, 1610, and 'Lou Catounet Gascon,' 1611; a version of Homer's 'Batrachomyomachia,' in Gascon, 'La Granoul-Batromachio,' Toulouse, 1664; 'La Pastourale (a comedy in 4 acts) deu Paysan que cerque mestié a son bila,' in the dialect of Béarn by Foudeville de Lescar, Pau, 1767; 'L'Embarras de la Fieiro de Beaucaire,' by Michel, Amsterdam, 1700; 'Actes du Synode de la Sainte Reformation,' Montpelier, 1599, a satire against the Calvinists, by Reboul, a witty but profligate adventurer, who was at last executed at Rome, under pope Paul V., in September, 1611, in consequence of his undiscriminating satirical propensity; 'Lou Banquet,' par Augié, Gaillard, Paris, 1583; the 'Jardin deys Musos Provençales,' Aix, 1628; &c.

In Spain the Latin language became corrupted, though perhaps less rapidly and at a later date than in Italy and France, which is proved by the fact that during the 8th and 9th centuries masters were procured from the Peninsula to teach that language in Italy. It is another evidence of this, that till the beginning of the 12th century, Latin, though corrupt, was the only language used among the Christian population of the Peninsula, not only in the acts of the cortes and councils, but also in the municipal fueros, the public edicts, diplomas, testaments, and the writings of authors. It was also the language of the tribunals, until San Fernando, about the middle of the 13th century, caused the 'Liber Judicum' to be translated into the vulgar tongue.

The corrupt Latin of Spain gave rise to the Catalonian and Valencian, the old Portuguese or Galician, and the Castilian or modern Spanish. The last two, and especially the Castilian, received a considerable admixture of Arabic words (said to be about 2000 in the Spanish language), from which the Catalonian remained comparatively free. The process of corruption of the Latin into Romance was the same as in France and Italy, and may be traced even in the writings of the clergy, who professed to use the literary language of the country. Elipando, bishop of Toledo, a man of learning for the time, who strongly opposed the introduction into Spain of the tenets of the supremacy and infallibility of the Roman see, writes to Felix, bishop of Urgel, in the following style: "Domino Felice, sciente vos reddo quia vestro scripto accepi . . . . direxi vobis scriptum parvum de fratre Militane . . . . ego vero direxi epistolam tuam ad Cordoba," &c.

It is impossible to fix the epochs of the origin of the various languages of the Spanish peninsula. The Catalonian and Galician or old Portuguese appear to be the oldest. The Castilian, notwithstanding the assertion of Bouterwek to the contrary, was not formed in the 11th century; its oldest existing monument, the poem of 'El Cid,' is not older than the year 1200. Previous to the 12th century the Galician, or old Portuguese, appears to have prevailed in all western Spain. An old manuscript Cancioneiro in this dialect, belonging to the library of the Royal College of the Nobles at Lisbon, of which Sir Charles Stuart obtained a copy, which he communicated to Raynouard, speaks of the Galician dialect as being spoken in Galicia and in Portugal, as far south as Coimbra, in the 10th and 11th centuries, after which the Portuguese grew into a separate and polished dialect, which was much in use for poetry among Galicians and Castilians as well as Portuguese. (Raynouard, 'Grammaire Comparée,' Discours Préliminaire.)

In the 'Elucidação das Palavras, Termos, e Frases que em Portugal antigamente se usárão,' 2 vols. fol., Lisbon, 1798, are other specimens of old Portuguese or Galician compositions. The original text of the 'Amadis de Gaula,' by Vasco de Lobeira, which is lost, was written in the same language.

The Catalonian dialect became early a literary language, and as such subject to fixed grammatical rules; it has its grammars and dictionaries, a great number of printed books, and a still greater number in manuscript. It had its historians; among others an anonymous historian of Catalonia, mentioned by Zurita in his 'Chronicas de Aragon;' Bernard de Sclot, who lived in the 13th century, and wrote a history of the principality of Catalonia and of the Aragonese kings subsequent to the junction of the two states; and King Jayme I. of Aragon, who wrote an account of his own reign, which has been published under the following title: 'Chronica o Commentari del gloriosissim e invictissim Rey Jaume Rey d'Aragó de Mallorques e de Valencia, Compte de Barcelona e de Urgell, e de Muntpellier, escrita per aquell en sa lengua natural, e treta del Archiu del molt magnifich Rational de la insigne Ciutat de Valencia, hon estava custodita,' Valencia, 1557. King Jayme also wrote a book 'de la Saviesa' 'on wisdom,' quoted by Nicolas Antonio, in his 'Bibliotheca Vetus.' The Catalonian is rich in poetry, which was introduced into the Peninsula by the Troubadours of Provence and Languedoc. Alonso II. of Aragon, in the 12th century, is numbered among its poets, as well as Guillermo de Berguedan, a Catalonian noble, who lived in the following century, and some of whose verses are preserved in a manuscript in the Vatican library. Mosen Pero March, Jacme March, Mosen Jorde, Mosen Febler, and Ausias March of Valencia, rank also among the Catalonian, Aragonese, and Valencian Troubadours. [TROUBADOURS.]

The languages of Aragon and Valencia, in the time of the Aragonese monarchy, may be considered as one and the same with the Catalonian. It is worthy of remark, that at the end of the 13th century, when the Castilian language had already gained the preponderance in a great part of Spain, we find a controversial conference between the Jews of Granada and some Christian missionaries from Castile, carried on in the Catalonian language, which appears to have been vernacular at Granada. ('Memoirs of the Royal Academy of Barcelona,' i., p. 615.) In the same Memoirs (p. 613) it is stated that the bishop of Orense, having been requested to examine what analogy there might be between the vulgar Galician and the Catalonian, answered, that there were in both, not only nouns, verbs, and other parts of speech quite identical, but also entire phrases. And Terreros (in his 'Paleography') and others have stated, that the language of Asturias is the same as that of Galicia, bating the difference of pronunciation.

The Catalonian, observes Raynouard, is the living language which most resembles the old Romance of the Troubadours, and that of the Valdenses of Pignerol in Piedmont is the next. The following are among the shades of difference between the Catalonian and the Romance:—1. The Romance substantives and adjectives ending in *an*, *en*, *in*, and *un*, add in Catalonian the euphonic final vowel *y*; *affan*, *affany*, *estran*, *estrany*, &c. The plural feminine in *as* is changed into *es*. The Catalonian often changes the *s* into an *x*; *axi*, *puix*: it doubles the *l* at the beginning and at the end of words; *aquell*, *lloch*, *lluny*; it sometimes changes the *e* into an *i*, especially of the Romance participles in *ent*; *dormint*, *servint*, *fugint*, *premint*: it adds a final *u* to some inflections of the verbs, &c. The Catalonian has retained the affixes of the Romance, of which the following are specimens taken from the poems of Ausias March, the Valencian Troubadour:

> Mottra *m* la llum de vera esperança,
> Be *ns* mostra Deu lo mon que vol finir
> Tot mon parlar als que no *us* auran vista,
> No solament los leigs qui *t* venen contra.

The popular patois or dialects of the south of France, after being long neglected, have of late years attracted the attention of philologists. Colomb de Batines has given an account of the patois of Dauphiné; Sainte Beuve inserted a notice in the 'Revue des Deux Mondes,' vol. x., 1837, of the poems of Jasmin, the barber poet of Agen; a 'Recueil de Poésies Béarnoises,' was published at Pau in 1827. (The Bearnese dialect is a Romance and not a Basque dialect, and resembles the Gascon.) The dialect of Gascony has been illustrated by the Viscount de Métivier: 'De l'Agriculture et du Défrichement des Landes,' Bordeaux, 1839; and also by Du Mege: 'Statistique des Départemens des Pyrénées.' The Languedocian boasts of two graceful poets, brothers: 'Poésias Patouesas de P. A. et Cyr. Rigaud,' Moupeyé, 1806; 'Mêlanges sur les Langues, Dialectes, et Patois,' Paris, 1831; Beronie, 'Dictionnaire Patois,' Tulle, 1820; the poems of Verdié, a self-instructed artisan of Bordeaux, who died in 1820—whose works, full of humour and nature, are unknown beyond the precincts of his native town; an imitation of the fables of Lafontaine, in the dialect of Limousin, by J. Fouçaud, 1835; Brunet, 'Notices et Extraits de quelques ouvrages écrits en Patois du Midi de la France,' Paris, 1840; Millin, 'Essai sur la Langue et la Littérature Provençale,' Paris, 1811; J. Champollion Figeac, 'Nouvelles Recherches sur les Patois ou Idiomes vulgaires de la France, et en particulier sur ceux du Département de l'Isère, suivies d'un Essai sur la Littérature Dauphinoise, et d'un Appendix contenant des pièces en vers et en prose peu connues, et un Vocabulaire,' Paris, 1809; Grinet, 'Vocabulaire Limousin,' a dialect which resembles those of Franche Comté and Western Switzerland.

With regard to the ancient Langue d'Oc, or Langue Romane, the most refined of all the southern dialects, but which may be considered now as a dead language, it was illustrated in the last century, in Italy, by Bastero, 'La Crusca Provenzale;' and in France, by L'Abbé Millot, 'Histoire Littéraire des Troubadours,' who compiled his work from the voluminous manuscript folios of M. de Sainte Palaye. In the present century, Raynouard has been the most industrious and most successful investigator of the Romance language and literature. His 'Lexique Roman, ou Dict. de la Langue des Troubadours,' was published in 6 vols. 8vo, Par. 1836–44. M. Honnorat has published a 'Dictionnaire Provencal-Française,' or Dictionary of the Langue d'Oc, ancient and modern, 2 vols. 4to, Paris, 1846–49; and G. F. Burguy a 'Grammaire de la Langue d'Oil, ou grammaires des dialectes Français aux XII. et XIII. siècles,' accompanied by a glossary, 2 vols., Berlin, 1853–54. Other valuable works have also appeared, either written or edited by Mahn, Villemarque, &c.

In Italy, the dialect of the valleys of Pignerol, or of the Valdenses, has most affinity to the old Romance. The Piedmontese, which is a written language, and is spoken by all classes of people, bears also considerable affinity to the modern Romance dialects of Southern France, and we have heard it stated that natives of Languedoc can understand those of Piedmont with ease. Dr. Pipino published a Piedmontese grammar, Turin, 1783; and Ponza published, in 1827-8, a Dictionary, Piedmontese and Italian. The language of Nice is also a corrupt dialect of the Langue d'Oc.

With regard to the other North Italian or Lombard dialects, they differ more or less from the old Romance language, though they had a common and perhaps coeval origin with it, and resemble it more than the Italian or Tuscan. The Langue d'Oc, having been formed chiefly from a corrupt and provincial Latin, as well as the dialects of Italy, reduced its materials to a regular form sooner than they; and having become a polished and literary language, the Italians in their turn borrowed at second-hand from it. Raynouard, in his 'Grammaire Comparée,' observes that the dialect of Ferrara is one of those which has retained more completely the forms of the Romance with the least admixture. That of Bergamo comes perhaps the next in affinity: it often changes the *e* into *o*; for example, instead of *el*, *del* (Romance), it has made *ol*, *dol*. The dialects of Bologna and Mantua abound with contractions and aphæreses, which render them very harsh; they have taken away the *t* of the Romance terminations in *at*, *it*, *ut*. The Milanese has a broad pronunciation, and many double vowels, changing into *aa*, *ii*, and *uu*, the Romance terminations in *at*, *it*, and *ut*; *veritaa*, *servii*, *avuu*, &c.; it also changes *re* into *er*; *noster*, *sepolcher*, for the Romance *nostre*, *sepolchre*. The dialects of the Venetian territory, with the exception of that of Friuli, are more remote from the Romance in their formation, as are likewise still more so the dialects south of the Apennines, or of Southern Italy. We cannot here enlarge upon the multifarious subject of the Italian dialects, but must refer the inquisitive reader to their grammars, vocabularies, and other works.

The dialects of Western Switzerland, Vaud, Neuchâtel, Geneva, part of Freyburg and Lower Valais, and also of Savoy, have retained to this day the name of patois Romand, or Langue Romande. Western Switzerland, as far as the Aar, was occupied in the decline of the Roman empire by the Burgundians, a less rude tribe than the Alemanni, who settled in Eastern Switzerland. The Burgundians shared the land with the native population of Roman, Helvetian, or Allobrogic race; they applied themselves to agriculture, and soon constituted themselves into a well regulated and orderly monarchy. They gradually adopted the provincial Latin which they found in use in the country, and from the corruption of which several Romance dialects were formed, which resembled those of the south of France that were formed through a similar process. Some of the dialects of Western Switzerland approximate in their inflexions to the Northern French, or Langue d'Oïl, whilst others, like that of Gruyère in the canton of Freyburg, bear more affinity to the Romance of the south, and consequently to the Italian. Specimens of both are contained in Stalder's 'Dialektologie,' and also in the collection of Ranz des Vaches, both in German and Romance, 'Sammlung von Schweizer Kuhreihen und Volksliedern,' Bern, 1818. To this day, Switzerland is divided, by language, races, and habits, into German and Romande, and the Germans call the latter by the general name of Welschland.

In the country of the Grisons, or ancient Rhæti, one half of the people speak a language called Rumonsch, which is an Italian dialect of very ancient formation, supposed by some to be derived from the language of the Etruscans, who emigrated to those valleys about 600 years B.C.; but this is a mere conjecture. The Rumonsch is a written language, and books have been published in it. MSS. eight or nine centuries old existed at the end of the last century, and perhaps some still exist in the convent of Disentis. The dialect of the Engadina, or valley of the Inn, is called Ladin: it has still greater affinity to the Italian or Lombard dialects. Specimens of Rumonsch and Ladin are found in the Appendix to Vieusseux's 'History of Switzerland,' published by the Society for the Diffusion of Useful Knowledge. Raynouard observes that the Rumonsch has the affixes and other essential forms of the Romance language, though it is disfigured by an admixture of Northern or Teutonic orthography and pronunciation. It often adds a *g* to the end of words; *filg*, *volg*, *haig*, *testamaing*, for the Romance *fil*, *vol*, *hai*, *testament*.

If we take the appellation of Romance language in its most extended sense, all the languages and dialects of Western Europe, that is to say, of Italy, Western Switzerland, the Grisons, France, and Spain, may be called Romance, being derived essentially from the Roman or Latin, and having been formed after the fall of the Western Empire. The Basque and the Armorican or language of Lower Britanny belong to a different family. The Walloon of Lège and the Valachian are also Romance languages. The Valachian resembles the others, though less perhaps in its grammatical forms than in the etymology of the words. Raynouard shows the analogy existing between them all in their grammatical construction and etymology in his 'Grammaire Comparée des Langues de l'Europe Latine.' But if we take the word Romance in its more restricted sense, as having been especially applied to the language of the troubadours, or Langue d'Oc, we must consider it as confined to the south of France, and the eastern provinces of Spain as far as Murcia, and it is there that we find its legitimate offspring in the languages of Catalonia, Valencia, and Majorca, and in the Languedocian, Provencal, and Valdenses dialects.

Raynouard at the conclusion of his 'Grammaire Comparée' of the languages of Latin or Roman Europe, enumerates twenty-three special characteristics in the construction of the Romance language, most of which occur also in the other languages and dialects of Western and Southern Europe, which he styles 'Neo-Latin.' 1. The use of articles to determine the cases, instead of their being designated by the termination of the word as in Latin. This characteristic is found in all the modern languages derived from the Latin. 2 and 3. Relate to the terminations of words, especially nouns, of which Raynouard gives comparative tables in the various languages. 4. Is peculiar to the old Romance, but existed also in the Northern French till the 14th century. It consists in placing an *s* at the end of substantives in the singular, when they stand as subjects; the absence of the *s* shows they were used in the objective case. In the plural it was the reverse, the absence of the *s* designated the nominative. The Northern French dropped the *s* generally in the singular, and gave it to the plural without distinction. 5. Refers to other terminations employed by the old Romance, especially in proper names, to distinguish the subject from the object. 6. Concerns the gender of the adjectives. 7. Concerns the degrees of comparison. 8. Is on the Romance affixes representing personal pronouns, *ous*, *os*, *m*, *x*, which are also met with in the old French and old Spanish, and also in some rustic dialects of France, in the Catalonian, and in some north Italian dialects. 9. The pronoun *altre* is an expletive added to the personal pronoun. This has been adopted by all the Neo-Latin languages of Europe; *vous autres*, *vos otros*, *vos outros*, *voi altri*, &c. 10. Relative pronouns *qui*, *que*, *lo qual*. 11. The indefinite pronoun *om*, derived from the Latin *homo*, which the French has retained in *on*. The Spanish and Portuguese, which formerly employed *ome* in the same sense, have since substituted *se*, and the Italians *si*. 12. Concerns the use in the conjugations of the auxiliary verbs *aver*, *ester*, and *estar*, which have been adopted, with some modifications, by all the other Romance languages. 13 and 14. Concern the formation of the future and the conditional. 15. Concerns the participles in *ut*, of which the French has made *u*. 16. Concerns the double formation of participles of the same verb, such as *rot* and *romput*, *defet* and *defendat*, *eleit* and *elegit*, &c. 17. The compound passive formed of the auxiliary *esser* and the participle past, which has been substituted in all cases for the Latin simple passive form. 18. Concerns the verbs used impersonally. 19. The infinitive with the negative, used as an imperative. The Italian has retained it: "Non parlare:" speak not. 20. The various uses of the conjunction *que*. 21. Formation of adverbs from the feminine adjective by adding the affix *ment*, which has been adopted by all the other languages derived from the Latin. 22. The expletives *pas*, *mica*, *gaire*, &c., added to the negative particle to give it greater emphasis. This form is retained by the French in *pas*, and by the Italians in *mica* and *guari*. 23. Concerns the appellations *Romans*, *Romance*, *Roumonch*, *Romanza*, which were used by the old French, Italian, Spanish, and Portuguese writers to designate their respective idioms; an appellation which serves to show their common origin. The most recent general dictionary of the Romance language is the 'Lexicon Etymologicum linguarum Romanarum, Italicæ, Hispaniæ, Gallicæ, &c.,' of F. Diez, Bonn, 1853.

ROMANESQUE ARCHITECTURE is that style of round-arched architecture which (with local or national peculiarities) prevailed through a large part of Europe during the 11th and 12th centuries. Under BYZANTINE ARCHITECTURE, it was pointed out how the architecture of the ancient Romans diverged in the hands of their barbaric successors into a two-fold form: the older becoming moulded, in the Eastern Empire, into that known as the Byzantine style, and which was the parent of the subsequent ecclesiastical architecture of the east of Europe; and the later, that which in the Western Empire became in the hands of the ecclesiastical architects what is now known as Romanesque, and which, as was shown under GOTHIC ARCHITECTURE, became in its ultimate development, Pointed Gothic. Romanesque architecture then, both in time and place, stands between the classic Roman and the Pointed Gothic; and is, in fact, the link which connects the one with the other.

Until the final separation of the Western from the Eastern Empire, the Byzantine type was in the ascendant; but in the West such architecture as existed was rather a debased Roman, than an independent or derived style. Yet traces of the Romanesque appeared at a comparatively early date. Its germ was certainly visible in the 6th or 7th century; but this was followed by a long interval of quiescence. Some have fancied that the revival is due to the Lombard kings, and have consequently termed the style itself Lombardic. But the revivification of architecture does not seem to be really traceable farther back than the 10th century; the development of the style belongs to the 11th century, and its highest perfection to the 12th, when its obvious insufficiency to meet the growing requirements of the age led to the introduction of the feature which caused it to merge into what is usually regarded as a totally different style. Nor, as we have intimated, can it be especially assigned to any particular locality. Lombardy may have been the cradle of the actual Romanesque, but it soon spread through other parts of Italy; along the Rhine, in Germany and Switzerland; throughout France, and by way of Normandy to England. The styles of these countries are indeed frequently treated as though not only different but unconnected, but in principle they are essentially the same; the differences consisting of those local and national features which are due to the character of the inhabitants, and the physical (or geological) peculiarities of the country, and which are always found unless the inventive faculties are controlled by rigid ecclesiastical or professional precedents. We may say, however, that as the birthplace of the style was Italy, it was there that it retained most decidedly the resemblance to its original, the divergence from the classic type becoming more marked in proportion to its distance in place as well as time from its source. And whilst in other countries the Romanesque merged in the 13th century into Pointed Gothic, in Italy it maintained itself as the prevalent style till the advent of the Renaissance.

We shall here treat of Romanesque architecture generally: the peculiar forms it assumed in our own country, first in a very rude shape in the Anglo-Saxon, and afterwards in a more developed and artistic condition as the Anglo-Norman style, are noticed under Norman Architecture, and Saxon Architecture, to which articles we refer for many of the details necessarily omitted here, and which are in a measure applicable to the style in other countries.

The earlier buildings of Christian Rome were merely a degenerate imitation of the older buildings. From the establishment, if not from the tolerance, of Christianity the ancient basilicas were employed as churches; and the earliest churches erected, were modelled on the type of the basilica. Presbyteries, chapels, and other features were gradually added, and ultimately the church assumed the form of a Latin cross; but even then the principles of the basilica form were retained. [Basilica; Church.] In the buildings of the degenerate Roman period it was usual to employ the materials as well as to imitate the forms of the older edifices and columns, and other ornamental fragments were appropriated to places which they could only be made to fit by various modifications and contrivances. Hence the classic proportions, at first little heeded, were soon entirely forgotten, and the different parts of the building were designed according to the necessities of the case, or the taste or caprice of the architect. Arches were made of all sizes and placed anywhere. Columns were arranged without regard to the orders; and the dimensions of the shafts were regulated merely by the weight they had to sustain. Mouldings and carvings assumed the most irregular and fantastic patterns.

Thus, then, we perceive, when Romanesque architecture was emerging from the chaos, references in all its parts to ancient Roman forms and principles, but the utmost licence in their application; and what the architects of the period did, was to reduce the discord into order, and to mould the whole into a consistent system. Among the distinctive characteristics of this style in its maturity may be mentioned in the first place, its general massiveness of construction and severity of character. The walls are usually of great thickness and pierced by windows of a comparatively small size and few in number. Indeed, in nothing does pointed Gothic differ more markedly from the round-arched style out of which it grew than in the enlargement and the prominency given to windows—a characteristic due to the introduction of painted glass, and the admiration felt for it by the ecclesiastics of the west and north,—the decorations of the Romanesque, essentially of Italian origin, having been chiefly mural paintings and mosaics. But besides the massiveness of construction, a leading characteristic is the predominance of horizontal lines in the general composition, which again distinguishes this style from Pointed Gothic, in which a general tendency to verticality is as decidedly apparent.

The semicircular or segmental arch is distinctive of the style. It is employed for all purposes, and occurs of all sizes in the same building. Usually it is employed in combination with the columns, the column being made the essential support of the arch—all appearance of entablature being now discarded. At first the columns themselves were mostly tapering, not cylindrical like the slender detached ones met with in the Pointed style, and the capitals bore a more or less close resemblance to those of the Corinthian order in contour and proportion. The capital itself, however, was larger in proportion to the rest of the column, thereby affording a greater surface or impost for the arches to rest upon; and also combining the appearance of security at that point with general lightness of appearance. The shaft was mostly plain, yet frequently highly ornamental, striated or carved in different ways, and sometimes twisted, either singly or with two stems twining spirally round each other. Columns furnishing examples of all these different modes occur in the cloisters of San Paolo and San Giovanni Laterano at Rome, and the capitals present quite as much variety, it seeming to have been the aim on such occasions to introduce as much diversity as possible, instead of so arranging the columns as to have two of the same kind placed together: a practice probably originating in making use of fragments taken from other buildings, and afterwards retained as conducing to variety and richness.

Although the arches were, as frequently as not, quite plain, and without archivolt mouldings of any kind, the use of archivolts was by no means uncommon; sometimes consisting of merely a single moulding enclosing a plain border around the arch, at others divided into *fasciæ*, and more or less enriched, as in the front of the cathedral of Pisa, in which building the arches describe more than a semicircle above the capitals of the columns, being prolonged downwards by a deep abacus, consisting in some places of two, in others of a single plain block resting immediately on the capital. Similar blocks or *abaci* occur in the remains of Frederick Barbarossa's palace at Gelnhausen, where small heads or masks are introduced immediately above such abaci, so as to fill up the same space there between the arches, and continue in some degree the vertical lines produced by the columns.

In some Romanesque buildings the design consists of little more than an assemblage of arches variously disposed, the apertures for windows being few and small and destitute of ornament; and they generally form either successive tiers, one above the other, like so many blank galleries, or occur at intervals in the vertical line of the edifice. In these kinds of arcades [Arcade], that which is uppermost is generally of much smaller dimensions than the one beneath, so that two of its arches occupy no wider space than one of those below it. Another practice peculiar to this style is that of carrying a range of arches beneath a gable, ascending one above the other in the same sloping direction as the sides of the roof; instances of which occur in the fronts of the Duomo at Parma, San Michele at Pavia, and in those of the cathedral at Carrara, and the church of San Zeno at Verona, in which two latter instances, however, the bases of the columns are all on the same level, and consequently the columns themselves gradually increase in height as they approach the centre. The front of the cathedral at Pisa offers a double instance of the same kind in the upper, or gable story, and in the half gables over the ends of the second one, with the difference, that in the latter the pillars support merely blocks placed beneath the inclined line of the roof. To this may be added the very prevalent custom of making an upper cornice or border of very small interlacing arches, or of mouldings producing that appearance. Interlacing arches were also very common in the decorative arcades.

Among the other more prominent characteristics of this style, which are all that we can here touch upon, it should be noticed, that whether forming actual porticos and galleries, or closed up and applied merely as decoration, the arcades were generally small in proportion to the building itself, and instead of occupying the entire width of the front, or other elevation, were mostly inserted into distinct compartments of it, slightly recessed within the general face of the wall, so that the plain spaces between them assumed the appearance of buttresses, or, when narrow, of plain pilasters continued up to the cornice of the gable or roof, and cutting through whatever string-courses, or other horizontal mouldings (if there were any), divided the different stories or stages of the edifice. Such buttress-like surfaces—for buttresses they cannot properly be termed—were occasionally more or less enriched; sometimes so much so, as to produce vertical lines of ornament continued the entire height of the building, as in the front of San Michele at Pavia. When, as was frequently done, these surfaces were made wider at the angles of the front than elsewhere, they gave an expression of repose and of great solidity to it, serving as it were as a frame to the architectural decoration.

Pinnacles are of rare occurrence, and when introduced have the look of being set on the part they rise above, being separated from it by horizontal mouldings; besides which they are generally low, and somewhat resemble pedestals. Pinnacles of this description may be found surmounting pilaster-breaks, and cutting through either an horizontal cornice or the sloping cornices of a gable, as in the front of the cathedral at Monza.

Windows, as we have said, were for the most part sparingly introduced, and of small dimensions, so that they rarely contributed much towards embellishment; circular or wheel windows are, however, not unfrequently introduced in gables, and often with considerable effect. Doorways were generally made very important features, the chief ornament being lavished upon them. The aperture itself indeed was generally plain, and also square-headed, but it was enclosed in a recess formed by a series of arches one within another and resting upon columns; and so deep was this outer casing as to be frequently very nearly as wide as the actual doorway. Sometimes the tympanum was filled with sculpture, and the arches and capitals were very richly carved.

Vaulting is another important characteristic of the style. At first the ordinary Roman semi-cylindrical or waggon vaulting prevailed; but the awkward appearance of continuous vaulting supported by disconnected columns seems to have soon arrested attention, and the Roman quadripartite vaulting was introduced. This was succeeded by sexpartite, which met most of the immediate requirements of the case, but led to other innovations which in turn introduced new changes. Indeed, as Mr. Whewell, Mr. Scott, and other distinguished authorities have suggested, and as appears highly probable, it may have been the unceasing efforts of the builders to improve the system of vaulting which led to the use of the pointed arch, and ultimately to the adoption of the pointed style.

There are other points on which we might dwell, as the general employment of the apsidal termination, and the use of the triforium and the clerestory, but for these features it must suffice to refer to the articles Apsis, Clerestory, and Triforium; and again for the illustrations of details omitted here to Norman Architecture. We may, however, just add a word or two on *Towers*, a new and important feature in this style of architecture. In Italy, towers only occur as detached buildings [Campaniles], but in the Romanesque churches of Germany, France, and England, they are an essential and very characteristic portion. As the rule they are square in plan; massive in structure; pierced with a few narrow, round-arched windows, which are often coupled and enclosed with a larger arch; the surface is often ornamented with arcades; and they are surmounted occasionally with a low pyramidal spire. [Norman Architecture; Spire.] Occasionally round, and more rarely octagonal, towers are met with. In some towers circular windows are seen.

Cupolas occur in many Italian and some French churches of this date; but these may be regarded as evidence of a more or less direct Byzantine influence.

ROMANS, EPISTLE TO THE. The Epistle to the Romans has been almost universally admitted to be the work of St. Paul. The only sects which have disputed its genuineness are the Ebionites, the Encratites, and the Cerinthians, and these purely on doctrinal grounds, inasmuch as the doctrines of this Epistle were adverse to their own opinions. (Stuart's 'Commen. on the Epis.,' p. 42.) Some modern commentators, however, have supposed that the Epistle properly ends with the fifteenth chapter, a supposition which may seem plausible from the want of connection between the last chapter and the rest of the Epistle. But this want of connection may be accounted for easily enough, without any such hypothesis. (Stuart, 'Introd.,' p. 49.)

The verses 25-27 inclusive of this last chapter are in some manuscripts, as in the Codex Alexandrinus, made to follow ver. 23 of cap. xiv., and Griesbach and others give them this arrangement. But a doxology of so sublime a character as is contained in these verses does not seem a fit conclusion for a discussion about eating meats or abstaining from them, and accordingly Hug and others agree with the received text in placing them at the close of the Epistle. Some few manuscripts omit them altogether. The words *I, Tertius*, &c., xvi. 22, imply that this chapter formed the end of the Epistle, and that the Epistle is *one*. There are, however, indications in the last chapter that the Epistle received several unimportant additions or insertions after it was in the main completed, according as any afterthoughts occurred to the writer, before it was finally despatched.

With respect to the date of the Epistle, various years have been assigned to it, from A.D. 55 to A.D. 58. According to the most probable opinion, it was written towards the end of 57 or in the beginning of 58, when St. Paul was at Corinth, and on the point of setting out to Jerusalem with the "contribution made by them of Macedonia and Achaia for the poor saints which were at Jerusalem" and in Judæa (xv. 25, 26), and before he had ever visited Rome.

The Epistle was dictated in Greek by the Apostle to Tertius, his amanuensis (xvi. 22), and conveyed to the church at Rome by Phœbe (xvi. 1), a servant or deaconess of the church at Cenchreæ, a place not far from Corinth. Another proof of the Epistle having been written from Corinth is given in xvi. 23, where St. Paul sends salutations from Gaius, his host, and Erastus, the chamberlain of the city of Corinth. (Comp. 2 Timoth, iv. 20; and 1 Cor., i. 14.) The position of this Epistle in the New Testament does not depend upon its date, for it is the seventh in order of time according to most authorities, and is placed first, either from being the "longest and most comprehensive" of the Epistles of St. Paul, or from the importance of the church to which it was addressed. (Horne's 'Introduct.,' vol. iv.) With respect to the origin of this church, we have no certain information in the Scriptures. They do not tell us when or by whom it was founded. The opinion that it was founded by St. Peter does not appear to rest on any satisfactory evidence: the chief authorities for it are, Irenæus ('Adv. Hær.,' iii. 1) and Eusebius ('Chron. an. 2 Claud.'); but if he had indeed preached the Gospel at Rome, such a circumstance would probably have been noticed in the Acts of the Apostles, nor is it likely that St. Paul would have made no allusion to it in this Epistle. Perhaps the most reasonable opinion on the subject is, that the Gospel was first preached at Rome by "the strangers from that city, the Jews and proselytes," who were converted by Peter's preaching at Jerusalem on the day of Pentecost (Acts, ii. 10); so that, like many other churches, that at Rome was at first composed of Jews, and gradually increased by the admixture of Gentiles, till the whole Christian community there became so large and important, "that their faith was spoken of through the world." The fact of this combination and co-existence of Jews and Gentiles as parts of one Christian church sufficiently explains to a careful reader the occasion and object of the Epistle. Prejudices and pretensions on one side would be met with disdain or opposition on the other. (Cap. ii. and xi.) The Jews were attached to the Mosaic institutes, and the Levitical rites and distinctions between clean and unclean. They were impatient of subordination to or equality with the Gentiles, and wished to impose upon them a conformity to many points of the Mosaic ritual, especially that of circumcision, before they were admitted to a participation in the privileges of the Gospel. The Gentiles, on the other hand, disregarded (perhaps too contemptuously) the prejudices of the Jews, and were of course offended at their pretensions to superiority, for which their fallen position afforded in the eyes of the Gentiles no justification. They might not reflect with fairness on what the Jews conceived themselves to have lost by the publication of the Gospel. Such a position of parties, and such a state of feeling between them, would naturally give rise to the divisions and offences which occasioned some of the admonitions and cautions contained in the hortatory portion of the Epistle, and the existence of it can scarcely fail to be observed by a careful reader.

For examples of undesigned coincidence between this Epistle and the Acts of the Apostles, the reader is referred to Paley. The writers and commentators upon this Epistle, both English and foreign, have been exceedingly numerous.

RONDEAU (Fr.), or RONDO (It.), a kind of air consisting of two or more strains, in which, after finishing the second strain, the first is repeated, and again after the third, &c., always returning to and concluding with the first. (Rousseau.)

ROOD, the quarter of an acre. [Acre.]

ROOD-LOFT. In Roman Catholic churches a large crucifix usually occupies a conspicuous position at the entrance to the chancel. Prior to the Reformation the same custom was, of course, observed in English churches. The crucifix, here called a *Rood*, was placed on a beam—called the *Rood-Beam*—fixed across the chancel arch, or on the screen which divided the nave from the chancel; but more commonly in large churches the Rood was placed on a gallery called the *Rood-Loft*. The rood was of large size, painted in natural colours, sometimes ornamented in front with the emblems of the evangelists; and had figures of the Virgin and St. John standing one on each side of the foot of the cross—the figures being all turned towards the nave. The screen which supported the gallery was of wood or stone, often richly carved or panelled. A flight of stone steps in the wall of the nave usually led to the rood-loft; but in some instances the stairs were carried up an external turret. Roods are of great antiquity. A cross surmounting a chancel screen in the church of Santa Sophia, Constantinople, is mentioned by a writer of the 6th century; but there is no evidence of such a cross having a figure of Christ upon it before the 8th century. In England roods were introduced as early as the 11th century; but rood-lofts seem to have been first erected in English churches in the 14th century. The galleries as well as the roods were in most instances destroyed by authority in the reign of Edward VI., but more or less perfect examples remain in various country churches, among others at Banwell, Long-Sutton, Minehead and other churches in Somersetshire; Newark, Nottinghamshire; Great Handborough, Great Rollwright, and Charlton, Oxfordshire; Dartmouth and elsewhere in Devonshire; and Worm-Leighton, &c., Warwickshire. In some churches a small turret was erected over the chancel arch, and consequently over the rood, in which was hung the sanctus bell [Bell-Cote], and this was often called the *Rood-Tower*. The chancel-arch in like manner, from the rood being placed beneath it, was sometimes termed the *Rood-Arch*. On the continent the gallery-cross, in French *Croix de jubé*, had gradually fallen into disuse sometime before the present century, and old examples are now very rare. One of the most perfect is in the great church of Louvain. In Germany, France, and the Netherlands, the rood was often suspended from the chancel arch by three ornamental chains, of which fragments still remain in several churches.

ROOF, the covering of a house or other building. The name, in its most extended sense, embraces the external covering itself, and the framework by which it is supported; but, as a term in carpentry, it is limited to the carcass-roof or framing.

The importance of this part of a building can hardly be overrated, since on its right construction depends not only the comfort of those for whose shelter it is designed, but also the safety and durability of the edifice itself. For the former of these purposes it is desirable that a roof should exclude extremes of heat and cold, and be impervious to rain or snow. For the latter, the exclusion of water is equally necessary; and it is essential that the framework be so disposed as to throw the least possible strain on the walls. By a judicious arrangement in this particular, a roof may not only be prevented from pressing on the walls in an injurious manner, but may be made to contribute greatly to the stability of the whole structure. In order to the due combination of the requisite qualities, an intimate acquaintance with the principles of mechanical philosophy is indispensable; and a correct knowledge of the strength of different materials, when exposed to various kinds of strain, is necessary to the economical adjustment of the dimensions of the several parts of a roof. A roof of large span forms, indeed, one of the most interesting applications of the science of carpentry, theoretical or constructive.

In order to cover in a building in which the space to be spanned is greater than can be covered by single blocks of stone extending from one point of support to another, it is necessary either to have recourse to the principle of the arch, as in vaults and domes of stone or brick, or to form a framework of timber to support the covering. The former plan is objectionable in the case of ordinary buildings from its expense and weight, and from the great solidity required in the walls, where they have to be used as the abutments of an arch. The principles on which such coverings of masonry are formed are explained under Arch and Dome; and in this article the more usual kind of roof, that sustained by a wooden framing, will be described. Such structures occasionally partake of the character of an arch or dome, but more usually consist of flat planes variously disposed. Roofs formed of one level plane, which are extensively used in eastern countries, are not adapted for buildings in which a large space has to be spanned over, nor to resist the penetration of water, and are therefore unsuitable for climates in which rain and snow are common. A simple inclined plane is well adapted to resist injury from weather; but, as it is scarcely more favourable to an economical disposition of the timbers than a flat roof, it is only suited for small buildings, and is seldom used except as a lean-to. Another objection to its use on a large scale is the disproportionate height it requires on one side of the building. The best figure for a simple roof is that formed of two inclined planes, rising from the two opposite walls that approach nearest to each other and meeting over the centre of the edifice, so as to form a ridge. By this form, supposing the same slope to be maintained, one-half of the height of the single inclined plane is avoided; and the length of the timbers being diminished one-half, their scantling may be considerably reduced. *Fig.* 1 represents a plan with side and end views of such a roof, which is called a *common* or *gable-ended roof*. Frequently four inclined planes are used, disposed as shown in *fig.* 2, representing a *hipped roof*, which takes its name from the hips, or inclined ridges formed by the meeting of the sides and ends. Where a hipped roof covers a perfectly square building, the faces all meet in a point, and form a pyramid; but when, as in the diagram, the plan of the roof is oblong, the planes rising from the nearest opposite walls meet in a ridge. Sometimes the inclined faces are not continued upwards till they meet, but the roof is completed by a horizontal plane. Such a roof is called a *truncated*, *terrace*, or *cut roof*, and may have two, three, or four inclined faces. *Fig.* 3 represents a truncated roof hipped at one end, and terminating at the other in a vertical wall, like the gable-ended roof.

Fig. 1.

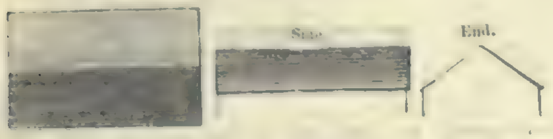

Fig. 2.

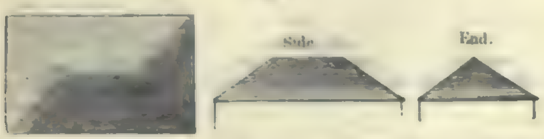

Fig. 3.

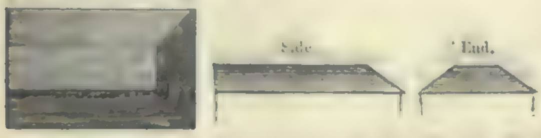
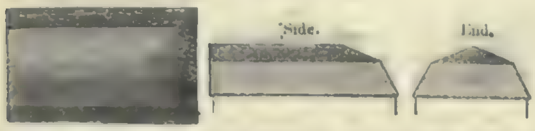


This arrangement is useful for diminishing the height of a roof, the level platform being covered with lead to compensate for the want of slope. It should be observed, however, that even this part is not perfectly level, the centre being slightly elevated to throw off water. A similar saving of height is frequently obtained by means of a roof in which each sloping face consists of two planes of different degrees of inclination. This form, which is denominated a *curb roof* (or, from its inventor, a *Mansarde roof*), is very common in London, because it affords more space for the formation of bedrooms in the roof than the simpler forms. A curbed roof may be hipped or not, according to circumstances. *Fig.* 4 represents it hipped at one end only, as the last figure, showing, like the previous diagrams, the plan, and side and end elevations.

Fig. 4.



Such are the principal forms of roof used in covering simple rectangular buildings, but they require many modifications to suit irregularities of shape or combinations of rectangular forms. Thus, in *figs.* 5 and 6, which represent the junction of different roofs or portions of roofing at right angles with each other, the lines *a a a* indicate *valleys*, or the junction of two planes in such a manner as to form hollows the reverse of hips. When two faces of a roof join so as to form an angle similar to a valley, but in a horizontal instead of an inclined position, the term *gutter* is applied instead of valley.

Fig. 5.

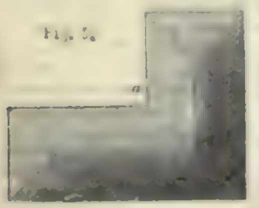


Fig. 6.

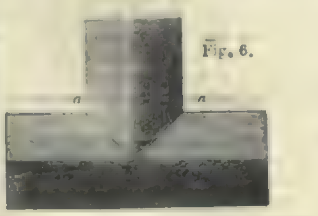

A further distinction, which it may be well to mention before entering upon the details of construction, is that between roofs with dripping eaves, and those in which the water is collected in gutters. In the former case the roof projects several inches, or even feet, beyond the walls, and the water running from the roof either drops at once on the ground, or is collected in troughs fixed under the margin of the eaves, and conducted by them to descending pipes. This arrangement has a clumsy appearance, and is perhaps unnecessary where a sufficient projection is given to the eaves, though it is essential to the dryness of the walls when they are of the diminutive size often adopted by modern builders. In gutter roofs the timbers do not extend to the outside of the walls, which are carried up as parapets, of a reduced thickness, to such a height as to conceal the roof either wholly or partially. The gutters, which are troughs of wood covered with lead or other metal, are laid at the bottom of the slopes, just within the parapets, and have a gentle inclination (usually about an inch in ten feet), to cause water to run freely towards the pipes. In extensive roofs it is well to use two or more falls instead of one, that the elevated end of the gutter may cover as little of the roof as need be. Similar troughs are often used in the valleys. Gutters are generally made wide enough for a man to walk along them, and should be sufficiently capacious to avoid all risk of overflowing during a sudden heavy fall of rain.

The degree of slope given to the inclined faces of a roof varies according to the covering material employed, as well as to the climate. The ancient Grecian temples had very low, or pediment roofs, varying from about 12° to about 16°, the height being from one-ninth to one-seventh of the span. In Roman buildings the inclination is somewhat greater, being usually 23° or 24°, or from one-fifth to two-ninths of the span. The general introduction of the pointed style of architecture led to the use of very high-pitched roofs, a very common proportion being that in which the length of the rafters is the same as the span, so that they formed an equilateral triangle. In comparatively modern domestic architecture in this country, it has been considered desirable for the length of the rafters to be three-fourths that of the span, and an angle of 45° is still considered by some to be the best pitch when plain tiles are used. As builders can, in the present day, obtain excellent covering materials, the pitch may be made of any required degree, down to the low Grecian pediment, and it therefore depends on the style of architecture and the taste of the builder; the most common height being from one-fourth to one-third of the span. High roofs discharge rain the most rapidly, and do not retain snow so much as those of low pitch; but where they have gutters they are liable to become choked by snow sliding into them, and to overflow from water running into them faster than the pipes can convey it away. Steep roofs may be covered with small slates, and are less likely to be stripped by violent winds. Low roofs, in consequence of their superior lightness, are less expensive, the timbers not only being shorter, but of proportionately smaller scantling, and they press less injuriously on the walls. The following table, extracted from Tredgold's 'Elementary Principles of Carpentry,' shows the proper angle for roofs covered with the materials specified in the first column, the last column indicating the comparative weight of each kind of covering:—

Covering.	Inclination to the horizon.	Height of roof in parts of the span.	Weight upon a square of roofing.*
Copper or lead	3° 50	$\frac{1}{48}$	copper 100 lead 700
Slates, large	22°	[illegible]	1120
„ ordinary	26° 33′	[illegible]	900 to 500
Stone slate	29° 41′	[illegible]	2380
Plain tiles	29° 41′	[illegible]	1780
Pan-tiles	24°	[illegible]	650
Thatch of straw, reeds, or heath	45°	$\frac{1}{2}$	

In describing the timber-work of an ordinary roof, each of the planes of which it is composed may be considered to be bounded by a frame, the parts of which have the general name of bordering pieces. Those which join the wall are the *wall-plates ;* that at the meeting of two faces, parallel to the wall-plates, is the *ridge-piece ;* and the inclined bars extending from the wall-plates to the ridge-piece are *rafters*, those which form the salient angles in hipped roofs being distinguished as *hip-rafters*. The support necessary for the external covering is given by a series of rafters or inclined bars, extending from the wall-plate to the ridge-piece, and placed parallel with each other at equal distances. In a hipped roof, the rafters near the ends, being parallel with the others, are necessarily diminished in length, extending from the wall-plate to the hip-rafter instead of the ridge-piece. All such pieces, being shorter than the length between the wall-plate and the ridge-piece, are called *jack rafters*.

It is not usual to vary the scantling, or transverse dimensions of rafters, in any considerable degree, on account of their various lengths; nearly the same scantling being used in all buildings, and the required strength being obtained by introducing intermediate supports between the wall plates and ridge-piece where the size of the roof renders such necessary. This additional support is supplied by horizontal rectangular bars called *purlins*, placed under the rafters in such a manner as to divide their length into two or more equal parts, the ends of the purlins being fixed to the sides of the bordering frame. Like the rafters, the purlins are not much varied in thickness according to the strain upon them, but they are in turn supported by a series of bars placed equidistant from each other, and parallel with the rafters. but with their upper face in the same plane as the lower face of the purlins. These are called *principal rafters*, or, for brevity, *principals*, to distinguish them from the first described, or *common rafters*. Where it is desirable to save room by reducing the thickness of a roof, the purlins may, as shown in *fig.* 15, be notched into the principals and common rafters, but this practice is not to be recommended, as it weakens the timbers. Where principals are used, their lower ends are morticed into the ends of a *tie-beam*, which stretches across the building, and rests upon the wall-plates. This beam keeps the lower extremities of the principals from separating, and discharges the weight of the roof on the walls in a vertical direction, relieving them entirely from the lateral thrust of the rafters. The triangular frame formed by the two principals and a tie-beam, with any bars it may comprise for additional strength, is called a *truss*, and such frames being placed at regular intervals, the timber work between any two of them is called a *bay of roofing*. The lower extremities of the common rafters, being elevated by this arrangement above the wall-plates, are supported by *pole-plates*, or pieces of timber parallel to the wall-plates, resting on the ends of the tie-beams. The supporting frame-work altogether is called a *carcass-roof*.

---

* A square of roofing contains 100 square feet.

Fig. 7, which represents a small carcass-roof supported by four trusses, and having one purlin only between the wall-plate and ridge-piece, may assist the reader in comprehending the arrangement of the parts enumerated; and their names will be found more distinctly by referring to the representation of a more complicated truss at *fig.* 11.

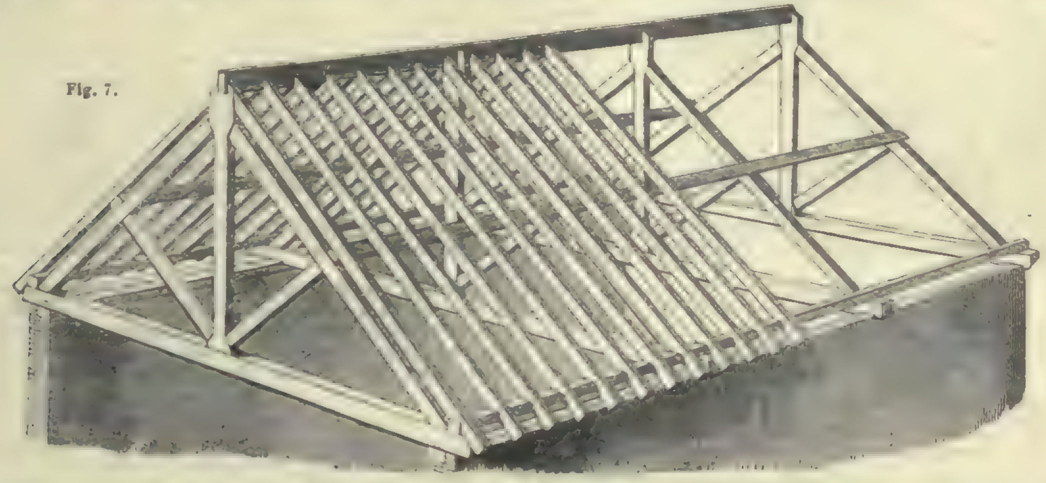

Fig. 7.

In *fig.* 7, the common rafters are represented on one half of the roof only, that the trusses may be more distinctly seen; and the end walls are omitted for the same reason.

The proper construction of the trusses of a roof, with reference to the size of the building, and the weight of the covering, is a matter requiring much scientific knowledge. For the want of this it is not unusual to encumber trusses with much more timber than is necessary or useful: and the disadvantage of this is not confined to the increased weight and cost of the roof, as superabundant timbers frequently occasion injurious strains, and the increased number of joints adds to the risk of derangement by the shrinking and warping common to all timber constructions. The general principles to be acted upon may be illustrated by a few diagrams; but in the limited space devoted to this article no attempt can be made to describe all the modifications required by the ever-varying forms of buildings; in the design of which it is too common, instead of assigning its due importance to the roof, to treat it as an unsightly feature, to be concealed as much as possible from view.

In a roof formed as shown in *fig.* 8, consisting simply of two inclined planes abutting on the walls, it is evident that the weight of the rafters *a b* and *b c*, as well as that of the covering sustained by them, will have a tendency to thrust out the walls. This tendency ordinary walls have not the strength to resist, and therefore it becomes necessary to add the beam *a c* (*fig.* 9), which by receiving the outward thrust of the rafters, relieves the walls of lateral strain. If the tension of the tie-beam *a c* be sufficient to resist the extending force of the rafters without sensible elongation, the only effect that such a roof can have upon the walls is a vertical pressure on each, equal to half its weight; and it cannot fall without the tie-beam, which acts the part of a cord or chain, being pulled asunder, or the rafters being crushed. If the materials were perfectly rigid, no additional parts would be required; but as they are not so in practice, it becomes necessary, when the timbers are of considerable length, to provide means for counteracting their tendency to sinking, or *sagging*. By adding a bar shaped like *b d* (*fig.* 10), the centre of the tie-beam may be suspended from the crown of the roof. This piece is called a *king-post*, but the name is perhaps not a good one, as, though it appears like a post to support the ridge or crown of the roof, it is in reality a *tie*, supported by it, and sustaining, instead of resting upon, the centre of the tie-beam. By cutting the king-post out of a piece of wood of larger scantling than the shank of the post itself, projections of the shape indicated in the cut may be formed at its ends. These are called *joggles*, and those at the upper end form a wedge between the heads of the rafters, like the keystone of an arch. It is evident that a weight pressing on the projecting joggles at the base of the king-post will be by it transmitted to the crown of the roof. These therefore form fixed points, from which support may be obtained, by means of *struts* or *braces*, *e* and *f*, for the centre of each rafter. Where purlins are added, they rest on those points of the principal rafters that are thus supported by struts, as may be seen by reference to *fig.* 7. It may be observed that this truss consists of two pieces (the tie-beam and king-post) in a state of tension, and four (the two rafters and the two struts) in a state of compression; and that in every well-contrived truss, however the number of its component parts may be increased, every bar is in one or other of these states. Those parts which are in a state of tension, acting merely as cords to bind the truss together, may be and sometimes are formed of slender rods of wrought-iron; but the others, needing stiffness as well as cohesion, require bars of considerable substance, and are therefore mostly formed of wood or cast-iron. Sometimes the king-post is dispensed with, and its office performed by two similar posts, called *queen-posts*, at equal distances from the centre of the truss. In order to keep these in their right position, a short horizontal beam, called a *collar-beam*, is inserted between their upper extremities, and another, termed a *straining sill*, between their lower ends. This arrangement is explained by *fig.* 11, which also shows the position of other parts of a truss. One side is represented as a gutter-roof, and the other with eaves.

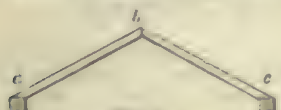

Fig. 8.

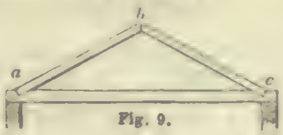

Fig. 9.

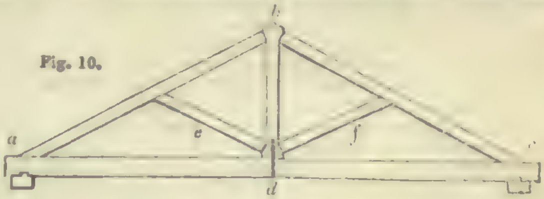

Fig. 10.

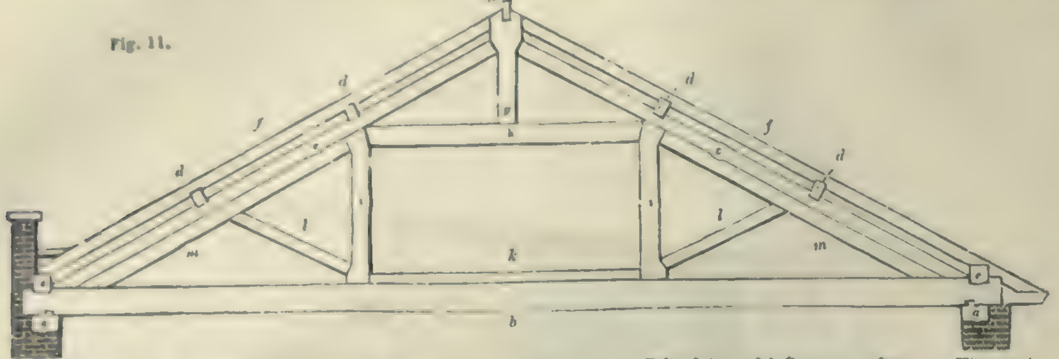
The *auxiliary* or *cushion rafters*, *m*, *m*, are pieces occasionally added, in large roofs, to strengthen the principals; and they, with the collar-beam, &c., form a complete truss within them. The trusses of truncated roofs are formed in this manner, the collar beam forming, as it were, the keystone of the arch, and being surmounted by a *camber-beam*, the upper edge of which is formed into two slightly inclined planes, to give the necessary slope to the lead covering. In such a roof, pieces of wood resembling ridge-pieces are inserted at the angles formed by the meeting of the rafters with the horizontal bars that support the flat.

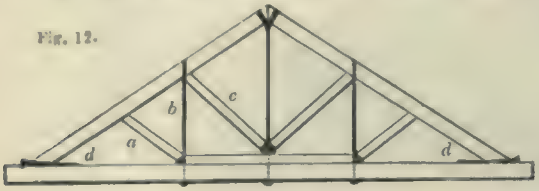
Fig. 12, is a representation of a very simple truss, from Nicholson's 'Carpenter and Joiner's Companion,' which illustrates the use of slender king-posts and queen-posts of wrought iron, and shows how the stress of every part of the roof may be brought to bear on the ridge. The lower ends of the struts rest in stirrups attached to the vertical rods and the weight bearing on the strut *a* is imparted, through *b* and *c*, to the king-post. The tie-beam is suspended by bolts from each of the vertical rods, and the ends of the rafters are secured to the tie-beam by iron straps passing round them, and bolted to the beam at *d*, *d*. Trusses on the same principle may be made of timber only.

Fig. 11.



a a, Wall-plates; *b*, Tie-beam; *c c*, Principal rafters; *d d d d*, Purlins; *e e*, Pole-plates; *f f*, Common rafters; *g*, King-post; *h*, Collar-beam; *i i*, Queen-posts; *k*, Straining-sill; *l l*, Struts or braces; *m m*, Auxiliary rafters; *n*, Ridge-piece.

Fig. 12.



In curb roofs the upper rows of rafters are called *curb-rafters*, and the horizontal bars that receive the upper ends of the lower rafters, and the feet of the curb-rafters, are known as *curb-plates*. The proper position of equilibrium for the rafters of a curb-roof may be ascertained by very simple means, within the reach of persons not possessed of sufficient mathematical knowledge for determining it by calculation. If the rafters are to be equally loaded, as in a roof entirely covered with one material, this position will be exactly the reverse of that which they would take by gravity, were they suspended in a chain or festoon, the joints being flexible. If they are framed together in this position of equilibrium, they will balance each other like the stones of an arch; and the tie-beams, posts, and braces will have no other office to perform than that of resisting such irregular strains as might tend to alter their arrangement. The rafters thus suspended would fall into the position *a b c d e*, *fig.* 13, a line drawn through the angles being a catenarian curve; and *a′ b′ c′ d′ e′*, in the same figure, represents the corresponding position in which they should be placed in an equally loaded roof. If the rafters *b′ c′* and *c′ d′* are to bear a greater weight than *a′ b′* and *d′ e′*, they will, if proportionately loaded when suspended in a curve, fall in such a way as to increase the angles *a b c* and *c d e*, and diminish *b c d*, thereby indicating their proper position in the roof. When the roof is to be loaded unequally, and more on one side of the ridge than the other, as it would be if *b′ c′* were to be covered with lead, and the other planes with slates, a corresponding weight added to the centre of gravity of *b c* will cause the bars to arrange themselves as *a b c d e*, *fig.* 14, the angles of which, being transferred to the roof, give the position of equilibrium *a′ b′ c′ d′ e′*. This practical method of finding the proper angles of a curb-roof may be applied under all circumstances, the dimensions of the experimental bars being proportionate to those of the rafters, and their centres of gravity being loaded according to the pressure to be sustained by each plane of the roof. The great advantage of curb-roofs consists in the space they afford for chambers in the roof, such chambers being lighted by dormer windows in the lower inclined faces. When the trusses of the roof form partitions between the bed-rooms, their posts and braces are so arranged as to leave one or more doorways for communication between them.

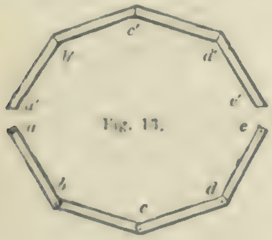


Fig. 13.

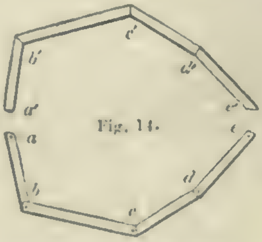

Fig. 14.

In roofs of very large span it is often desirable, in order to avoid running up to a great height, to form two or more ridges. When intermediate support can be obtained from partition walls, such constructions may be regarded as combinations of two or more distinct roofs placed side by side. *Fig.* 15 is an example of a roof of large span without any intermediate support, and having a large available space between the tie and collar beams. It represents the form of the trusses, which were placed fifteen feet apart, of a roof of eighty feet span, erected over Drury-Lane Theatre in 1793.

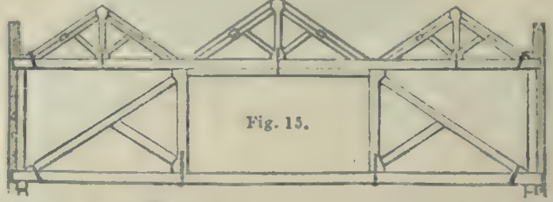

Fig. 15.

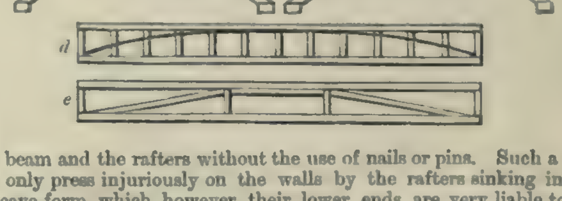
It is sometimes necessary, in order to obtain additional height inside a building, to raise the tie-beam above the level of the top of the walls. In small spans this may be done by the simple arrangement called the *carpenter's boast* (A, *fig.* 16), in which a firm union is effected between the beam and the rafters without the use of nails or pins. Such a roof can only press injuriously on the walls by the rafters sinking into a concave form, which however their lower ends are very liable to do. In such a case additional strength may be obtained by inserting a longitudinal truss, as in B, *fig.* 16, where *c* represents the end of the truss, which should be firmly built into the gables: *d* and *e* are side views of two longitudinal trusses suitable for such a situation, the first being stiffened by an arch of iron notched into the short vertical pieces, and the second formed of timber only. Similar trusses are occasionally introduced under the purlins. Roofs without ties may be greatly strengthened by the use of parabolic curves of iron, notched into the rafters of each inclined face, and abutting on the wall-plates, which in such a case are firmly bolted together. The timbers of such a roof may be framed together in planes, each having a distinct ridge-piece, and the ridges being screwed or otherwise firmly connected together. The curves may be cast in short segments, as they are compressed when in use, it being merely necessary to provide that the joints should always abut on a rafter. Tredgold, in his 'Elementary Principles of Carpentry,' recommends the use of similar curves, of either wood or iron, in the trusses of an ordinary roof, by which the derangement often arising from the shrinking of the king-posts and queen posts may be avoided. In this case the curves take the place of the principal rafters, and, if made of wood, may be constructed of

Fig. 16.



short straight pieces, arranged as shown in *fig.* 17, and held together by bolts or wooden keys. When curved timber can be obtained it is to be preferred, as it reduces the number of joints. For small roofs timbers may be bent into the required form, as it is found that a piece of wood the thickness of which does not exceed $\frac{1}{120}$th part of its length, may be bent into a curve rising one-eighth of its span without impairing its elasticity. Two such pieces may be laid together, and bent by twisting a rope attached to their ends, as is done in tightening the frame of a bow or pit saw; and, being bolted together while curved, they will spring back but little when the rope is relaxed. Another mode of forming such a rib is to take a piece of wood whose thickness is about one-sixtieth of its length, and cut along the middle with a thin saw from each end, leaving about eight feet in the centre solid. The beam may then be bent, and bolted or pinned together as before described. In either case the rib should be bent about one-fourth more than it is intended to remain, to allow for springing back. A parabolic curve is the form most recommended; but a circular arc, rising half the height of the roof, will answer the purpose. *Fig.* 18 represents the truss of a truncated roof strengthened by a curved rib, the suspended pieces being, when the rib is formed in the manner first described, placed at each joint, and each consisting of two pieces, one on each side of the rib, notched to it and the beam, and fastened by bolts and straps.

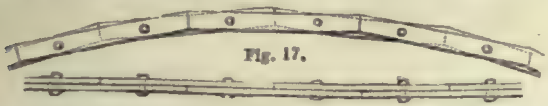


Fig. 17.

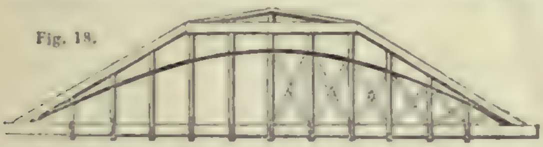

Fig. 18.

One of the advantages of this mode of construction is that the tie-beams may be suspended from any number of points, which is important in large spans, where the beams have to be formed of several pieces scarfed together. [SCARFING.] Diagonal braces, though unnecessary with parabolic curves, may be added to meet accidental strains, as shown by the dotted lines in the cut. This principle of construction, with an arc composed of several pieces of timber, was followed in one of the largest roofs ever built—that erected in 1791 over a riding-house at Moscow. The span of this roof, which has been said to be the most extensive wooden roof in the world, is stated by Tredgold at 235 feet, the slope being about 19°, and the external dimensions of the building 1920 by 310 feet. He states that it had sunk so much that it was proposed to add a second curve for additional strength.

A simple and economical roof, invented by Mr. A. H. Holdsworth, and rewarded by the Society of Arts in 1820, is supported by curved ribs of timber applied in a different manner. A detailed description is given in the 38th volume of the Society's 'Transactions;' but *fig.* 19 will sufficiently explain the principle of its construction: *a* is a beam serving as a tie-beam, and also to support the upper floor of the building; *b b* are curved ribs, formed in a similar manner to those just described, the lower ends of which are firmly secured to the tie-beam *a*. The principal rafters rest on these ribs, and their lower ends bear upon short timbers resting on the walls, these pieces being fastened by strong iron straps to the curved ribs, to counteract the outward thrust of the rafters. By this arrangement the whole of the interior of the roof, which is usually encumbered with king-posts, queen-posts, braces, &c., is rendered available for useful purposes, in addition to which it effects a considerable saving of timber.

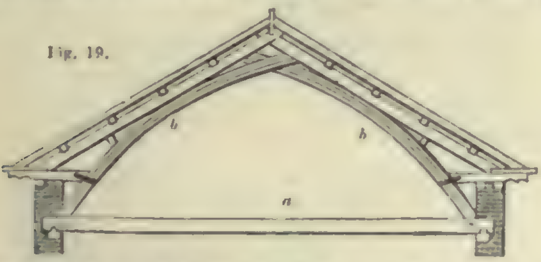

Fig. 19.

Wrought iron straps of various forms are very useful, when judiciously applied, in strengthening the joints of a roof. They should be fixed with regard to the unavoidable tendency of the timbers to shrinking, so that while they may, in some cases, counteract or lessen its effect, they may so far yield to it as to prevent a strain which should come upon a timber, being entirely thrown, by its alteration of form, upon the strap. Tie-beams are often suspended to the trussing-posts by means of straps, so arranged as to allow the beam to be keyed up to its true position in case of the roof sinking. When this is not the case, the ties are sometimes drawn up into a slightly convex or cambered form, to meet the same contingency. Height may be gained inside a building by disposing the timbers as in *fig.* 20, the want of a continuous tie-beam being compensated for by an iron strap to unite the ties to the bottom of the king-post at *a*; but it is evident that the safety of the plan must depend wholly on the straps, which alone counteract the outward thrust of the rafters.

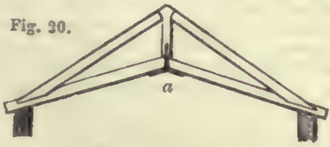

Fig. 20.

In roofing a church with a nave and side aisles, the continuity of the tie-beams may be dispensed with, intermediate support being obtained from columns. It is however necessary to guard carefully against any lateral strain to the columns.

Many of the high-pitched roofs of old Gothic churches and halls are very ingeniously contrived, but they often throw great pressure on the walls, owing to the absence or elevated position of the ties; thereby rendering very solid walls and buttresses necessary. The *Norman roof* is an ingenious but complicated contrivance for the construction of roofs of large span with small pieces of wood. *Fig.* 21 shows this arrangement, in which all the rafters abut on joggled king-posts, of which there are several, their relative position being maintained by diagonal braces. The timbers of this kind of roof are often left visible, being so carved as to have an ornamental effect. Such a roof may be made to exert very little injurious pressure on the walls.

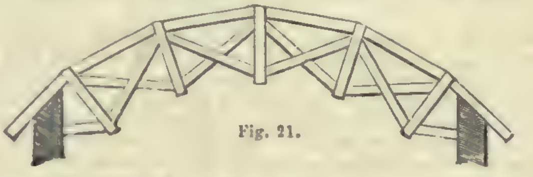

Fig. 21.

When the space covered in is of an irregular shape, it is best to arrange the inclined planes of the roof in a similar manner to those of a rectangular building, leaving a level platform in the centre, corresponding to the plan of the inclosed space. Where the space covered is circular, elliptical, or polygonal, although the construction of the roof may appear more complicated to the eye, it is, in fact, simpler and easier than that of a quadrangular building, the strain of the roof being more equally distributed. The nearer a roof approaches to a circle in plan, the stronger it will be, the parts deriving that mutual support from each other which forms the distinguishing character of the dome. Domes of wood, of great size, have been made without trussing, simply by forming the timbers into curved ribs abutting on the wall-plates, which then form a circle, and are kept in their proper positions by horizontal circles framed with them at intervals. As the ribs approach the upper part of the dome, the intervals between them diminish in width, to allow for which every second or third rib is discontinued at intervals, the ends of the ribs thus discontinued being received by the horizontal circles, which may be compared to purlins, the ribs taking the place of rafters. The wooden dome formerly existing at the Halle aux Blés, at Paris, was a remarkably bold example of this kind, being 200 feet in diameter, and having a large opening in the centre. It was built at the suggestion of M. Moulineau, and, having been destroyed by fire, has been replaced by a similar structure of iron, but of smaller dimensions.

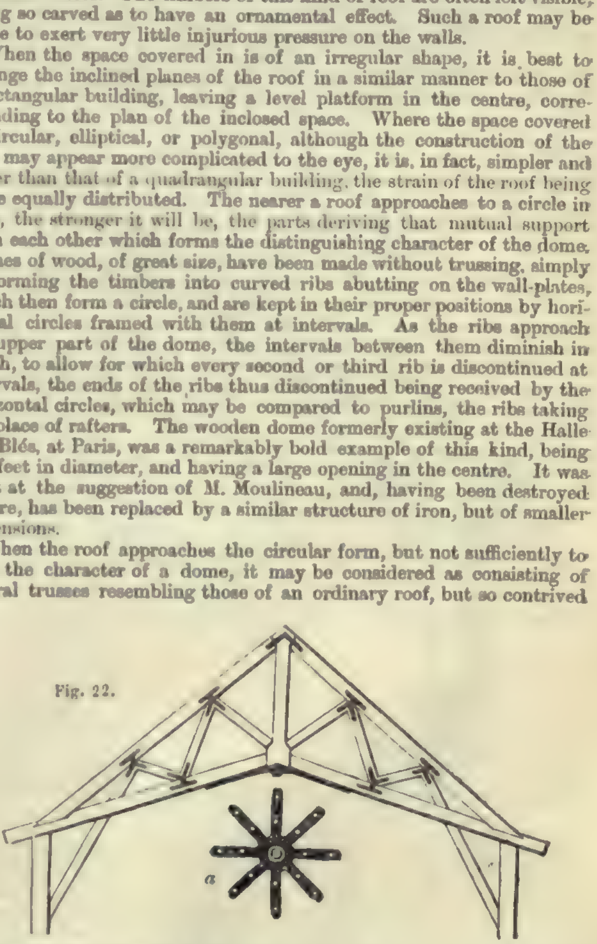

Fig. 22.

When the roof approaches the circular form, but not sufficiently to have the character of a dome, it may be considered as consisting of several trusses resembling those of an ordinary roof, but so contrived as to intersect each other in the centre; the king-post being common to all the trusses. *Fig.* 22, representing a design for a polygonal roof, from Nicholson, may illustrate this, and exemplify also some of the applications of iron straps: *a* shows the form of the strap by which the ties are secured to the king-post; the post having as many faces, and the strap as many arms, as there are trusses in the roof.

Though the number of contrivances for the construction of roofs is very great, as may be seen by reference to various works on carpentry, allusion can here be made to only one or two others. An admirably simple plan for making a very flat roof is described in the 37th volume of the 'Transactions' of the Society of Arts, in a communication from the inventor, Mr. Smart. The beams or rafters are cut, with a circular saw, as shown at *a*, *fig.* 23, while *b* represents their form when in use, a wedge being inserted between the ends of the parts that are elevated into a sloping position. These may be raised to an angle of 10° or 12°, and will bear a great weight, as they cannot be depressed without thrusting off the ends of the beam, or breaking the lower part of it by tension. This is called, by the inventor, the *bow and string rafter*, and was used by him to support a roof at the Ordnance Wharf, Westminster Bridge. Strong laths were nailed upon the rafters, and on these a platform of bricks was laid in cement, the whole being covered with tiles also bedded and pointed with cement, and twice coated with hot linseed-oil. The cost of this roof is stated to be not more than half that of lead.

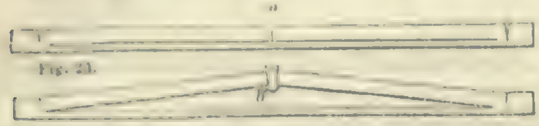

Fig. 23.

About thirty years since Colonel Emy, of the French Génie Militaire, applied, on a large scale, the system of bending thin planks into arched ribs to support the rafters of roofs of considerable span, erected over riding schools and building slips, &c.; and the system has also been applied in the construction of timber bridges for railways, with clear openings even of 133 feet. For the latter purpose the laminated timber arches have failed, on account of the entrance of moisture between the separate laminæ, and the consequent rotting of the beams; but in roofs, or in other positions where the arches are not exposed to occasional efforts of a nature to cause the laminæ to open, the beams do not rot, and there seem to be decided economical advantages in the application of Colonel Emy's system. It has been introduced in the Great Northern Railway Station in London, and in the station of the Baden Railway, at Freiburg, with great success; in both cases the spans are not less than 100 feet; the riding schools built by Colonel Emy, generally speaking, had a span of about 60 feet. A sketch of one of them is appended (*fig.* 24) and a description of the mode of putting the principals together is to be found in Emy's very valuable 'Traité de la Charpenterie.'

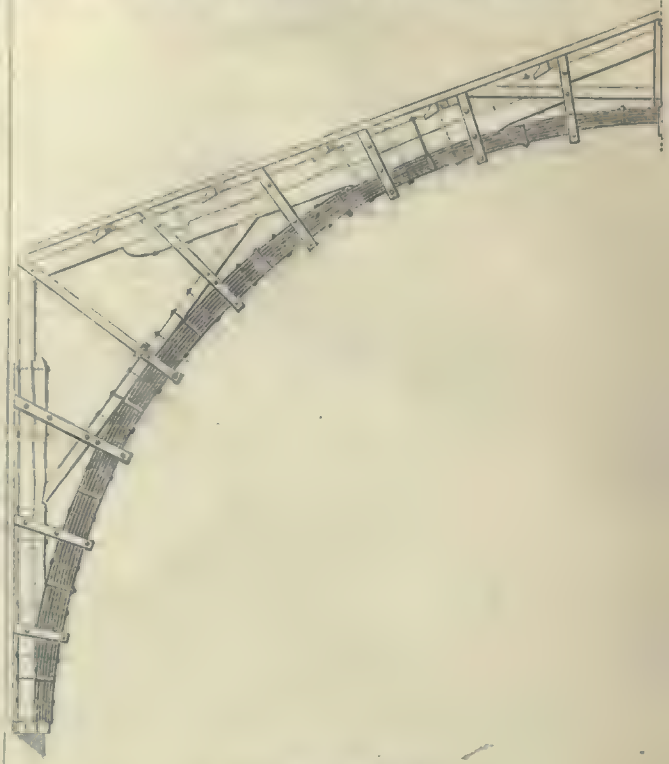

Fig. 24.—Riding School of Marac.

Colonel Ardant, also of the French Génie, has however published a work under the title of 'Études sur les Charpentes à grande portée,' in which he shows that these bent timber principals are not so advantageous, or so strong, as built beams of a polygonal form, of square timber, properly framed, and bolted together. The great objection to the use of the bent timber ribs was considered by Colonel Ardant to lie in their tendency to resume the straight line, or, in other words, the elasticity of the laminæ gave rise to a considerable force which tended to thrust out the side walls; and in fact this danger was actually found to exist at the Great Northern Railway Station, London, to so great an extent as nearly to lead to the overthrow of the whole shed. It would, however, be easy at any time to counteract the thrust of a principal of this description, and the bent timber ribs are no doubt very convenient and economical in many positions. Local considerations, therefore, ought alone to determine the selection of

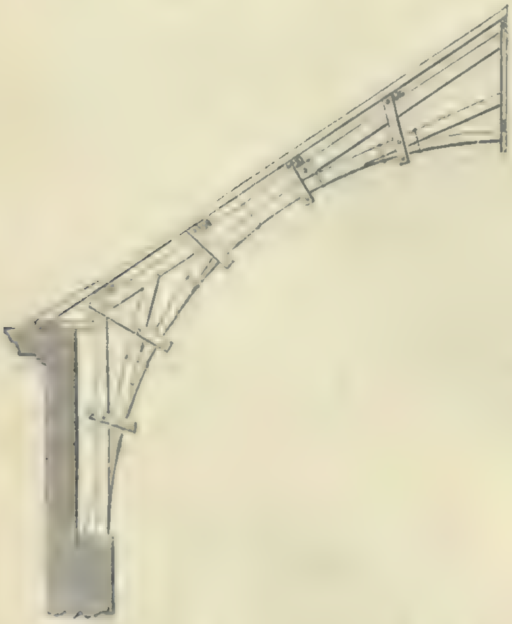

Fig. 25.—Ardant's Roof.

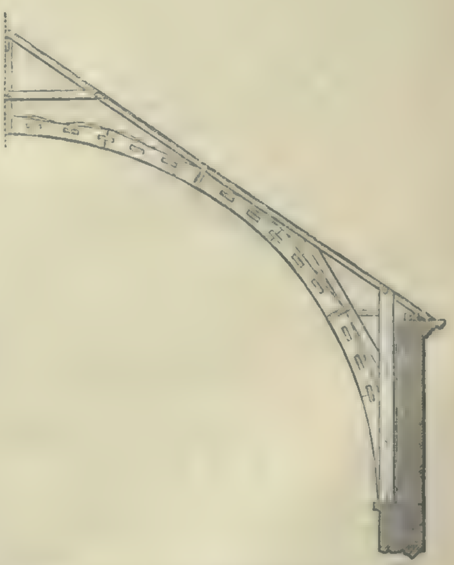

Fig. 26.—Roof of the Riding School, Metz.

either Emy, Ardant, or Philibert de l'Orme's systems of executing large timber roofs without tie-beams. In the main, they are all founded on the same principle—that of introducing a rigid beam for the purpose of supporting the principal rafter; the differences consist in the manner in which the physical properties of the wood are brought into action. In Emy's beam the elasticity of the bent planks is the great element of resistance; in Ardant and de l'Orme's principals, the wood resists mainly efforts of compression.

Some illustrations are appended of the most remarkable wrought-iron roofs executed of late years, principally to meet the requirements of the railway communications. They are, in their effect, light and elegant, even though costly; and it is precisely on account of these artistic qualities, and of the danger from the warping of complicated assemblages of timber, such as must be used in roofs of large span, that the preference is generally given to iron over wood roofs for railway sheds, wherein the principals are always exposed to view, and to the direct action of the atmosphere. The best work upon the strength and the construction of this class of roofs is Morin's, 'Leçons de Mécanique Pratique,' vol. iv. An important remark to be made with respect to these iron roofs is that the steam and smoke from the locomotives have a deleterious influence upon them; and for this reason they cannot be used where the locomotives in steam are likely to remain long under them.

In the valuable practical works of Nicholson, Tredgold, &c., the methods of calculating the strength necessary in the various parts of a roof may be found; and in the 'Principles of Carpentry,' by the latter author, tables are given of the dimensions suitable for different spans. The table here quoted refers to a roof similar to *fig. 7*; the trusses being not more than ten feet apart, and the pitch at an angle of about 27° with the horizon, for a covering of slates. The scantlings are suited for yellow fir, and must be somewhat increased for timber of inferior quality.

Span.	Tie-beam.	King-post.	Principal Rafters.	Braces.	Purlins.	Common Rafters.
Feet.	Inches.	Inches.	Inches.	Inches.	Inches.	Inches.
20	9½ × 4	4 × 3	4 × 4	3½ × 2	8 × 4¾	3¼ × 2
22	9½ × 5	5 × 3	5 × 3	3¾ × 2½	8½ × 5	3¾ × 2
24	10½ × 5	5 × 3½	5 × 3½	4 × 2½	8½ × 5	4 × 2
26	11½ × 5	5 × 4	5 × 4½	4½ × 2½	8¾ × 5	4¼ × 2
28	11½ × 6	6 × 4	6 × 3½	4½ × 2½	8¾ × 5½	4½ × 2
30	12½ × 6	6 × 4½	6 × 4	4¾ × 3	9 × 5½	4¾ × 2

For the strength of different materials, under various circumstances, the reader may consult Materials, Strength of. As a general remark, it may be observed that oak, when exposed to tension, is weaker than fir, and is therefore less adapted for ties. Being, however, less compressible, it is usually preferred for rafters, straining pieces, and struts; but Tredgold observes that its greater tendency to warping in summer renders it less fit for rafters and purlins than foreign fir. Cast-iron is not much used in the framing of wooden roofs, excepting for shoes, king-post heads, bolt-heads, and collars at the feet of struts and straining pieces. Wrought-iron is very useful for straps and fastenings, and also for ties and trussing-posts; but care is always necessary to guard against imperfections, which are more likely to pass unobserved than in wood. Wherever iron is applied, provision should be made for its expansion and contraction, and it is desirable to protect it from oxidation by painting. Though iron is far stronger for its size than any kind of timber, it is neither so strong nor so cheap as yellow fir, *weight for weight*, provided the spans of the roofs are moderate.

The joints in the frame-work of a timber roof are of various kinds according to the nature of the strain they have to resist. They should be formed with great care, and with due regard to such probable changes of form as all constructions of timber are liable to from shrinking and warping. *Cocking* or *cogging* is the name given to that kind of joining in which one piece of timber, in a state of tension, is so attached to another that it cannot be drawn away without one piece breaking. *Figs.* 32 and 33 represent two methods of cocking the ends of tie-beams on the wall-plates, giving a plan and elevation of each. In both figures *a* represents the beam, and *b* the wall-plate. In the first plan, which was formerly much practised, the contraction of the dovetailed end of the beam would allow it to be drawn considerably out of its place, and would therefore permit the walls to spread: but in the second the amount of contraction is diminished, owing to the small width of the rectangular tongue that enters the tie-beam, while its position is such as to prevent the beam being drawn out of its place beyond the actual extent of the contraction of the tongue. The shrinking of the joggles of king-posts and queen-posts is often productive of serious derangement, a circumstance greatly in favour of the substitution of iron for wood for such parts, especially in large roofs. This inconvenience is sometimes avoided by making the upper ends of the principal rafters abut immediately upon each other, as represented in *fig.* 12. A similar arrangement is made, in some cases, where wooden king-posts are used, the king-post and rafters being strapped together with iron. The sinking of a roof, particularly if it be of low pitch, is very injurious to the mortise-and-tenon joints of the struts and rafters, by throwing the strain on the shoulders of the tenons in such a way as to break off the tenons or splinter the wood. To guard against such injuries, it has been proposed by M. Perronet, a French engineer, instead of making the tenons and joggles square, to form them into circular arcs, the centres being at the opposite end of the strut or rafter. This plan appears worthy of general adoption, as it allows the joints to accommodate themselves to changes of form without injury. All the timbers of a roof are usually fitted and framed together on the ground, and taken to pieces again before being elevated to the building.

Fig. 32.

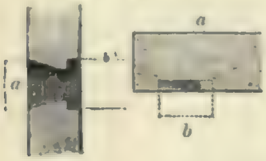

Fig. 33.

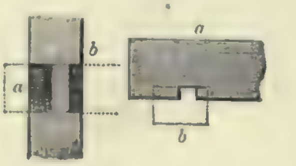

Allusion has been made in a previous column to the various materials used for the covering of roofs, with reference to the different degrees of inclination suitable for them. Thatched roofs have been considered by some to maintain the most equable temperature in the buildings covered by them, keeping out alike the extreme heat of summer and cold of winter. They are objectionable on account of their harbouring vermin, being easily damaged by wind, and dangerously combustible. The frequent repairs required make thatch also an expensive material. Besides straw, reeds and heath are sometimes used for thatching, and possess the advantage of greater durability. Tiles admit heat and moisture more than good slates. Pantiles, having no holes for nailing through, are simply hung, by ledges, upon laths nailed to the rafters. Plain tiles, laid in mortar, and over-lapping, so as to be of double thickness everywhere, make a very good though heavy covering. Tiles of a peculiar form, called *hip-tiles*, are used for covering salient angles; and *gutter-tiles*, which are similar to them, but placed with the concave side upwards, in the valleys or receding angles. Slates are laid in various ways. They are sometimes nailed down on a close boarding; or, if large, on *battens*, or pieces of wood from two and a half to three inches wide, and three-quarters of an inch to an inch thick, which are nailed to the rafters at intervals regulated by the length of the slates. Lozenge-shaped slating is occasionally used, and has an ornamental appearance, but is easily injured, as there is but one nail through each slate. It is always laid on boarding. For what is called patent slating the best large slates are selected, and fixed without either boarding or battening, the common rafter being placed at such a width as to come under the joints. The slates are screwed down, the courses over-lapping about two inches. The meeting joints are covered by fillets of slate about three inches wide, set in putty, and screwed down; and the hips and ridges are sometimes covered in the same manner, though it is best in all such cases to use lead. Patent slating, when well executed, is water-tight with as low a slope as one in six. In some districts laminæ of stone are used in lieu of slates or tiles. Shingles, which are like slates, but made of wood, were formerly much used in covering pyramidal steeples, and in roofs of steep pitch. They are still used in the United States, and are usually laid on boarding, in a similar manner to common slates.

Sheets of metal are very convenient for covering domes, and curved or angular surfaces generally; and also for flat roofs, or such as have too little slope for slating. Lead is the most common material for such purposes, though copper, iron, tinned iron, and recently zinc, are also used. Lead terraces or flats are commonly laid on boarding or plaster. The joints are sometimes soldered, but the most approved method is to roll or wrap the edges into each other, making allowance for expansion and contraction. A fall of a quarter of an inch in a foot is sufficient for surfaces covered with sheet metal.

Cements of various kinds have been applied to the formation of roofs, and in some cases with success, though they have often been found to crack, and thereby become permeable to water. Mixtures of tar with lime, sand, gravel, ashes, &c., have been recommended; and asphalte has been applied to this purpose, apparently with great advantage. Compositions of tar, resin, and similar substances, spread upon sheets of coarse paper, have also been used.

ROOT. The mathematical use of this term has gradually been extended, until it may be defined as follows: every value of an unknown quantity which satisfies a given equation is called a root of that equation. Thus, 2, 1, $1+\sqrt{(-3)}$ and $1-\sqrt{(-3)}$ are the roots, and all the roots, of the equation

$$x^4=5x^3-12x^2+16x-8,$$

since they are the only algebraical formulæ and arithmetical numbers which satisfy it. On this general use of the term root, see Theory of Equations and Involution.

The more common use of the term root is as follows: the seventh root of 8 is the incommensurable fraction whose seventh power is 8, or the solution of the equation $x^7=8$. There are altogether seven such solutions, one only arithmetical, the others of the form $a+b\sqrt{(-1)}$; the method of obtaining the arithmetical solution has already been discussed in the article Involution; the importance of the Square Root will justify its consideration in an article apart. We reserve for the present article the method of finding and using any root (in the common sense) of any algebraical quantity.

Every algebraical result is of the form $a+b\sqrt{(-1)}$ at widest, or may be reduced to that form. Here a and b are meant to be real algebraical quantities, that is, reducible to positive or negative whole numbers or fractions, commensurable or incommensurable. Thus, if $b=0$, we have the simple real quantity a; if $a=0$, we have the simple impossible quantity $b\sqrt{(-1)}$. It is indifferent, as to the present article, in what light the impossible quantity $\sqrt{(-1)}$ is considered; whether [Algebra] upon that extended system of definitions which makes it explicable and rational, or upon the more common system in which it is used without such explanation: for we are now merely considering all algebraic formulæ as results, subject to certain laws by which their use is to be regulated, and without any reference to interpretation. When we desire to consider only the arithmetical root of an arithmetical quantity, we shall use the symbols $\sqrt{}$, $\sqrt[3]{}$, $\sqrt[4]{}$, &c., but the exponential fractions $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, &c., will denote any one of the algebraical roots of a formula. Thus $\sqrt{16}$ means simply 4; but $(16)^{\frac{1}{2}}$ is an ambiguous symbol standing for either $+4$ or -4. And when we have an equation which presents an ambiguous formula equated to an unambiguous one, we mean that the unambiguous side of the equation is *one* of the values of the ambiguous one: in this sense $(1)^{\frac{1}{3}}=\frac{1}{2}(-1+\sqrt{(-3)})$. When we use the simple arithmetical symbol $\sqrt{}$ before an algebraical quantity, as in $\sqrt{(-3)}$, we merely mean to signify that the two values of $(-3)^{\frac{1}{2}}$ are distinguished into $+\sqrt{(-3)}$ and $-\sqrt{(-3)}$.

Let us now take a quantity of the form $a+b\sqrt{(-1)}$. Assume $r\cos\theta=a$, $r\sin\theta=b$, which gives

$$r=\pm\sqrt{(b^2+a^2)}\qquad\tan\theta=\frac{b}{a}.$$

Let us choose for r, which is called the *modulus* of the expression, the positive value $\sqrt{(b^2+a^2)}$. We can then always make the angle θ give the equation

$$a+b\sqrt{(-1)}=r\cos\theta+r\sin\theta\sqrt{(-1)}\,\ldots\ldots(1)$$

identically true. If a and b be both positive, θ must lie between 0 and a right angle, or between 0 and $\frac{1}{2}\pi$ [ANGLE]: if a be positive and b negative, θ must lie between $\frac{3}{2}\pi$ and 2π: if b be positive and a negative, θ must lie between $\frac{1}{2}\pi$ and π: and if both be negative, θ must lie between π and $\frac{3}{2}\pi$. Thus reducing angles to degrees and minutes,

$$2+3\sqrt{(-1)}=\sqrt{13}\left\{\cos\ 56^\circ\,19'+\sin 56^\circ\,19'.\sqrt{(-1)}\right\}$$
$$-2+3\sqrt{(-1)}=\sqrt{13}\left\{\cos 123^\circ\,41'+\sin 123^\circ\,41'\sqrt{(-1)}\right\}$$
$$2-3\sqrt{(-1)}=\sqrt{13}\left\{\cos 303^\circ\,41'+\sin 303^\circ\,41'\sqrt{(-1)}\right\}$$
$$-2-3\sqrt{(-1)}=\sqrt{13}\left\{\cos 236^\circ\,19'+\sin 236^\circ\,19'\sqrt{(-1)}\right\}$$

Generally, if a and b be positive, and if, returning to the arcual mode of measuring angles, θ be that angle which lies between 0 and $\frac{1}{2}\pi$ and has $b:a$ for its tangent, we must use θ for $a+b\sqrt{(-1)}$, $\pi-\theta$ for $-a+b\sqrt{(-1)}$, $2\pi-\theta$ for $a-b\sqrt{(-1)}$, and $\pi+\theta$ for $-a-b\sqrt{(-1)}$.

Again, since $\theta+2k\pi$ has the same sine and cosine as θ, when k is any whole number, positive or negative, if we take θ so as to satisfy (1), we find that the following is also satisfied:

$$a+b\sqrt{(-1)}=r\left\{\cos(\theta+2k\pi)+\sin(\theta+2k\pi).\sqrt{(-1)}\right\}\ldots.(2)$$

for all integer values of k positive or negative, but for no fractional value of k whatsoever. This and various other results of common trigonometry should be familiar to every student who attempts the present subject.

Common multiplication makes it obvious that

$$\left\{\cos x+\sin x.\sqrt{(-1)}\right\}\left\{\cos y+\sin y\sqrt{(-1)}\right\}=\cos(x+y)+\sin(x+y)\sqrt{(-1)}$$

for all real values of x and y; so that if we represent $\cos x+\sin x.\sqrt{(-1)}$ by ηx we have $\eta x\times\eta y=\eta(x+y)$. Now in BINOMIAL THEOREM it is proved that this equation cannot be universally true without giving as a consequence $(\eta x)^n=\eta(nx)$, for all values of n, whole or fractional, positive or negative. We have then

$$\left\{\cos x+\sin x\sqrt{(-1)}\right\}^n=\cos nx+\sin nx.\sqrt{(-1)}\ldots.(3)$$

an equation which goes by the name of De Moivre's Theorem. It is the key of the present subject.

Let it now be required to raise the nth power of $a+b\sqrt{(-1)}$, n being integer or fractional, positive or negative: this includes every case of raising a power, extracting a root, performing both operations, and taking the reciprocal of any result. Reduce $a+b\sqrt{(-1)}$ to its equivalent form $r\eta(\theta+2k\pi)$, or

$$r\left\{\cos(\theta+2k\pi)+\sin(\theta+2k\pi).\sqrt{(-1)}\right\},$$

whence $\left\{a+b\sqrt{(-1)}\right\}^n$ is $\left\{r\eta(\theta+2k\pi)\right\}^n$ or $r^n\eta(n\theta+2nk\pi)$, or $\left\{a+b\sqrt{(-1)}\right\}^n$

$$=r^n\left\{\cos(n\theta+2nk\pi)+\sin(n\theta+2nk\pi).\sqrt{(-1)}\right\},$$

in which r^n is found by purely arithmetical operation, and $\cos(n\theta+2nk\pi)$ and $\sin(n\theta+2nk\pi)$ by aid of the trigonometrical tables. So many distinct values as the variation of k enables us to give to $n\theta+2nk\pi$, so many values do we find of $\left\{a+b\sqrt{(-1)}\right\}^n$. Two angles are distinct when they are unequal, and do not differ by 2π or a multiple of 2π.

Firstly, let n be a whole number, positive or negative, then $2nk$ is always an integer even number, and there is only one value, namely,

$$\left\{a+b\sqrt{(-1)}\right\}^n=r^n\left\{\cos n\theta+\sin n\theta.\sqrt{(-1)}\right\}.$$

Next, let n be a fraction in its lowest terms, and, choosing an example, say $n=\frac{4}{5}$. Let us examine all the values of k, from $k=-5$ to $k=+5$, making $A_k=n\theta+2nk\pi$.

$$A_{-5}=\frac{4}{5}\theta-8\pi,\quad A_{-4}=\frac{4}{5}\theta-\frac{32}{5}\pi,\quad A_{-3}=\frac{4}{5}\theta-\frac{24}{5}\pi,$$
$$A_{-2}=\frac{4}{5}\theta-\frac{16}{5}\pi,\quad A_{-1}=\frac{4}{5}\theta-\frac{8}{5}\pi,\quad A_0=\frac{4}{5}\theta,\quad A_1=\frac{4}{5}\theta+\frac{8}{5}\pi,$$
$$A_2=\frac{4}{5}\theta+\frac{16}{5}\pi,\quad A_3=\frac{4}{5}\theta+\frac{24}{5}\pi,\quad A_4=\frac{4}{5}\theta+\frac{32}{5}\pi,\quad A_5=\frac{4}{5}\theta+8\pi.$$

Here it would seem as if from this set of the possible values of k, we get eleven distinct values of the fifth root of the fourth power of $a+b\sqrt{(-1)}$. But a moment's inspection shows that A_{-5}, A_0, A_5, are not distinct in effect, since they differ by multiples of 2π; neither are A_{-4} and A_1, nor A_{-3} and A_2, nor A_{-2} and A_3, nor A_{-1} and A_4. Also it will be found that for every value of k

$$A_{k\pm5},\ A_{k\pm10},\ A_{k\pm15},\ \&\text{c.},$$

are all angles which differ, each from its predecessor, by 2π; so that there are but five distinct angles in the whole series, which may be found by taking A_k, A_{k+1}, A_{k+2}, A_{k+3}, and A_{k+4}, with any value of k positive or negative. And generally, if n be a fraction whose denominator (when the fraction is reduced to its lowest terms) is q, it will be found that there are q distinct values of $\left\{a+b\sqrt{(-1)}\right\}^n$ and no more.

The most important cases are those in which $r=1$, or $a^2+b^2=1$, in which $\cos\theta+\sin\theta\sqrt{(-1)}$ may represent the expression. And of this particular case, the most important more particular cases are

$$\begin{array}{ll}\theta=0 & \cos\theta+\sin\theta\sqrt{(-1)}=1\\ \theta=\pi & \cos\theta+\sin\theta\sqrt{(-1)}=-1\\ \theta=\frac{1}{2}\pi & \cos\theta+\sin\theta\sqrt{(-1)}=\sqrt{(-1)}\\ \theta=\frac{3}{2}\pi & \cos\theta+\sin\theta\sqrt{(-1)}=-\sqrt{(-1)}\end{array}$$

Of these again, the two first are the most important.

Let $n=1:q$, and let the question be to find the q qth roots of 1. Putting unity in the form $\cos 2k\pi+\sin 2k\pi.\sqrt{(-1)}$, all these roots are the distinct values of $\cos\frac{2k\pi}{q}+\sin\frac{2k\pi}{q}\sqrt{(-1)}$ or $\left\{\cos\frac{2\pi}{q}+\sin\frac{2\pi}{q}\sqrt{(-1)}\right\}^k$.

Let $\cos\frac{2\pi}{q}+\sin\frac{2\pi}{q}.\sqrt{(-1)}=\alpha$, $\cos\frac{2\pi}{q}-\sin\frac{2\pi}{q}.\sqrt{(-1)}=\beta$.

Then $\alpha\beta=1$, as will be found by multiplication, and $\alpha^k=\beta^{-k}$: $\alpha^k=\alpha^{k\pm q}=\beta^{-k\pm q}$, since $\alpha^q=1$. Consequently, since the series of powers of α, positive and negative, are successions of qth roots of 1, the series of powers of β will be the same; and we may therefore select these roots at convenience from either series, or partly from one and partly from the other. Thus, if we would have the ten tenth roots of unity we may form them in pairs, as follows:—

$$\begin{array}{llll}\alpha^0\text{ and }\beta^0 & \text{give}\cos\frac{2.0\pi}{10} & \pm\sin\frac{2.0\pi}{10}\sqrt{(-1)} & \text{both}=1\\ \alpha^1\text{ and }\beta^1\text{ or }\alpha^9\ .\ . & \cos\frac{2\pi}{10} & \pm\sin\frac{2\pi}{10}\sqrt{(-1)} & \\ \alpha^2\text{ and }\beta^2\text{ or }\alpha^8\ .\ . & \cos\frac{4\pi}{10} & \pm\sin\frac{4\pi}{10}\sqrt{(-1)} & \\ \alpha^3\text{ and }\beta^3\text{ or }\alpha^7\ .\ . & \cos\frac{6\pi}{10} & \pm\sin\frac{6\pi}{10}\sqrt{(-1)} & \\ \alpha^4\text{ and }\beta^4\text{ or }\alpha^6\ .\ . & \cos\frac{8\pi}{10} & \pm\sin\frac{8\pi}{10}\sqrt{(-1)} & \\ \alpha^5\text{ and }\beta^5\text{ or }\alpha^5\ .\ . & \cos\frac{10\pi}{10} & \pm\sin\frac{10\pi}{10}\sqrt{(-1)} & \text{both}=-1\end{array}$$

Of these twelve forms, ten only are distinct, giving the ten tenth roots required. In this way the following theorems may be easily demonstrated.

1. The $(2m)$th roots of unity are $+1$, -1, and the $2m-2$ quantities contained in

$$\cos\frac{2k\pi}{2m}\pm\sin\frac{2k\pi}{2m}\sqrt{(-1)}$$

for all values of k, from $k=1$ to $k=m-1$, both inclusive.

2. The $(2m+1)$th roots of unity are 1 and $2m$ quantities contained in

$$\cos\frac{2k\pi}{2m+1}\pm\sin\frac{2k\pi}{2m+1}\sqrt{(-1)}$$

for all values of k, from $k=1$ to $k=m$, both inclusive.

3. If μ be one of the qth roots of unity, μ^2, μ^3, ... are also qth roots, but do not contain all the q roots, unless μ be made from a value of k which is prime to q. Thus, if $q=12$, and $k=1$, we get

$$a=\cos\frac{2\pi}{12}+\sin\frac{2\pi}{12}\sqrt{(-1)}$$

the list of roots is complete in 1, a, a^2, a^3, ... a^{11}, and a^{12} is 1, a^{13} is a, &c.

But if we make $k=8$, or take a^8 for μ, we have

$$\mu^2=a^{16}=a^4,\ \mu^3=a^{24}=1,\ \mu^4=a^{32}=a^8,\ \mu^5=a^{40}=a^4,\ \&\text{c.},$$

so that we get no roots from this series but a^8, a^4, 1, which are only the three cube roots of 1 (cube roots are among twelfth roots). But choose a^5 (5 is prime to 12) and its successive powers are a^5, a^{10}, a^{15} or a^3, a^{20} or a^8, a^{25} or a, a^{30} or a^6, a^{35} or a^{11}, a^{40} or a^4, a^{45} or a^9, a^{50} or a^2, a^{55} or a^7, a^{60} or 1, after which the series recurs in the same order.

4. If m be any factor of q, all the mth roots of unity are among the qth roots. Thus, if $q:m=v$, and if a be the first of the series of qth roots, the mth roots are a^v, a^{2v}, ... a^{mv} or 1. For $(a^v)^m=a^{vm}=a^q=1$, &c. All those powers of a which have exponents prime to q, may be called primary qth roots of unity: thus the primary 12th roots are a, a^5, a^7, a^{11}.

5. The qth roots of unity exist in pairs of the form $\cos\phi \pm \sin\phi \sqrt{(-1)}$. These pairs are a and a^{q-1}, a^2 and a^{q-2}, or a and a^{-1}, a^2 and a^{-2}, &c.

Let the question now be to find the qth roots of -1. If we now take

$$-1 = \cos(\pi + 2k\pi) + \sin(\pi + 2k\pi) \,.\, \sqrt{(-1)}$$

we have all the qth roots in the distinct values of the formula

$$(-1)^{\frac{1}{q}} = \cos\frac{(2k+1)\pi}{q} + \sin\frac{(2k+1)\pi}{q} \,.\, \sqrt{(-1)}.$$

Let $\alpha = \cos\frac{\pi}{q} + \sin\frac{\pi}{q}\sqrt{(-1)}$, then the qth roots required are α, α^3, α^5, ... α^{2q-1}, beginning with $k=0$, and ending with $k=q-1$. Thus, if μ be any one root, all the odd powers of μ (positive or negative) are also roots, but do not contain among them all the roots unless the value of $2k+1$, from which μ is derived, be prime to q. Thus if $q=15$, and if $\mu=\alpha^9$, we have (since $\alpha^{30}=1$)

$$\mu^3 = \alpha^{27},\ \mu^5 = \alpha^{45} = -1,\ \mu^7 = \alpha^{63} = \alpha^3,\ \mu^9 = \alpha^{81} = \alpha^{21},\ \mu^{11} = \alpha^{99} = \alpha^9\,;$$

so that we only get, from the powers of α^9, the distinct roots α^9, α^{27}, -1, α^3, α^{21}, which are also the fifth roots of -1. But if $2k+1$ be prime to q, all the qth roots of -1 may be obtained from μ. And if m be any factor of q with an odd quotient, all the mth roots of -1 are among the qth roots. Also these qth roots occur in pairs of the form $\cos\phi \pm \sin\phi\sqrt{(-1)}$, the pairs being α and α^{2q-1}, α^3 and α^{2q-3}, &c., or α and α^{-1}, α^3 and α^{-3}, &c.

Every qth root of -1 is one of the $(2q)$th roots of $+1$, and the $(2q)$th roots of $+1$ consist of all the qth roots of -1 and all the qth roots of $+1$.

The following equations will also be easily proved;

$$\{\sqrt{(-1)}\}^{\frac{1}{q}} = \cos\frac{(2k+\frac{1}{2})\pi}{q} + \sin\frac{(2k+\frac{1}{2})\pi}{q}\sqrt{(-1)}\,;$$

$$\{-\sqrt{(-1)}\}^{\frac{1}{q}} = \cos\frac{(2k+\frac{3}{2})\pi}{q} + \sin\frac{(2k+\frac{3}{2})}{q}\sqrt{(-1)}.$$

As it is not our object here to write on the applications of these formulæ, but only to supply an article of reference for those who may have forgotten or imperfectly learnt the groundwork of this very important branch of analysis, we finish here, referring to SERIES for such applications as fall within the plan of this work.

ROPE MAKING. A rope is a combination of fibres of hemp, or other material, so arranged as to form a flexible and tenacious cord or band; retaining, as far as possible, their collective strength. The name rope is generally confined to the larger descriptions of cordage, such as exceed an inch in circumference; though the principles of formation are much the same for cordage of every size.

If the fibres used by the ropemaker were of sufficient length, the most effectual way of obtaining their united strength would be to lay them side by side, fastened together at each end, so as to form a bundle or skein; but, as the fibres of hemp do not, on an average, exceed the length of 3½ feet, it becomes necessary, in order to obtain rope of greater length, so to twine them together that the strength of any single fibre shall be insufficient to overcome the resistance caused by the friction of those surrounding and compressing it; so that it will sooner break than be drawn out from the mass. This requisite entanglement is produced by twisting, which causes the fibres to compress each other; and it not only enables the ropemaker to produce cordage of any required length, but also, by making the rope hard and compact, increases its durability, and enables it to resist the penetration of water, which would rapidly impair its strength. While however some degree of twist is absolutely essential to the cohesion of a rope, any twist beyond that which simply prevents the fibres being drawn out without breaking, is injurious. A skein of fibres, or a rope, may be twisted so hard that any further attempt at twisting would break it; and such a skein will evidently have no power to support a weight, each fibre being already strained to the utmost extent that it will bear. In fact, whatever force is exerted by any fibre in compressing the rest, may be considered the same as a weight hanging on that fibre, and must be subtracted from its absolute strength before its useful effect can be ascertained; the available strength of a rope being the remainder of the absolute strength of its component fibres after deducting the force exerted in twisting them.

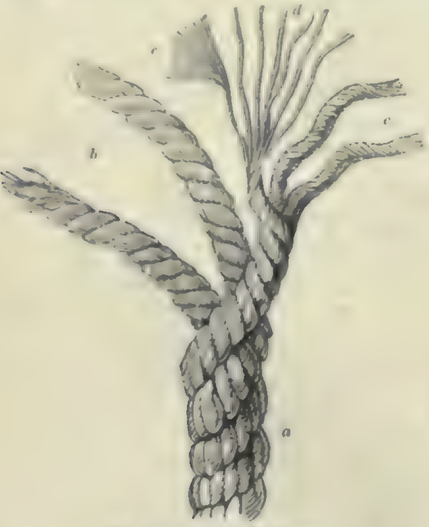

Fig. 1.—Analysis of a Rope.

Were a rope to be formed by simply twisting together, in one direction, the whole of the fibres of which it is composed, there would be nothing to prevent its untwisting as soon as left to itself. It is therefore necessary to twist the fibres in comparatively small portions, and so to combine these into a rope that the tendency to untwist in one part may counteract the like tendency in another. Thus the same force which would cause the component parts, if separate, to become loose or untwisted, is employed, when they are combined into a rope, to keep the whole firm and compact. This is illustrated in *fig.* 1, which may be considered as the unravelled end of a cablet or small cable. The cablet *a* may be untwisted into three smaller ropes, *b*; untwisting either of these in the opposite direction, we find it to consist of three smaller ropes, *c*; each of these may be untwisted into several small strings, *d*; and each of these consists of several distinct fibres of hemp, *e*. Thus several fibres form a *yarn*, several yarns a *strand*, three strands a *rope*, and three ropes a *cablet*.

With *fig.* 2 as an illustration, we may briefly describe the hand method of rope-making. The first process consists in twisting the hemp into thick threads, called rope-yarns. This process, which resembles ordinary spinning, is performed with various kinds of machinery. The common mode of spinning rope-yarns by hand is performed in the rope-ground, or rope-walk, an enclosed slip of level ground 600 feet or more in length. As many of the operations of a ropery would be impeded by wet weather, or by the unchecked heat of the sun, it is not unusual to cover the walk with a slight roof. At one end of this ground a spinning-wheel is set up, which gives motion by a band to several small rollers or whirls. Each whirl has a small hook formed on the end of its axis next the walk. Each of the spinners is provided with a bundle of dressed hemp, laid round his waist, with the bight or double in front, and the ends passing each other at his back. He draws out a sufficient number of fibres to form a rope-yarn of the required size; and, after slightly twisting them together with his fingers, he attaches them to the hook of a whirl. The whirl being now set in motion by turning the wheel, the skein is twisted into a rope-yarn; the spinner walking backwards down the rope-walk, supporting the yarn with one hand, which is protected by a wetted piece of coarse cloth or flannel, while with the other he regulates the quantity of fibres drawn from the bundle of hemp by the revolution of the yarn. The degree of twist depends on the velocity with which the wheel is turned, combined with the retrograde pace of the spinner. Great care is necessary in this operation to make the yarn of uniform thickness, and to supply the hemp equally from both sides of the bundle; because, if a considerable body of hemp be supplied to a yarn that is becoming too thin, it will not combine perfectly with it, but will form a loosely connected wrapper; and any irregularity in the last-mentioned particular will cause the fibres to bear the strain unequally.

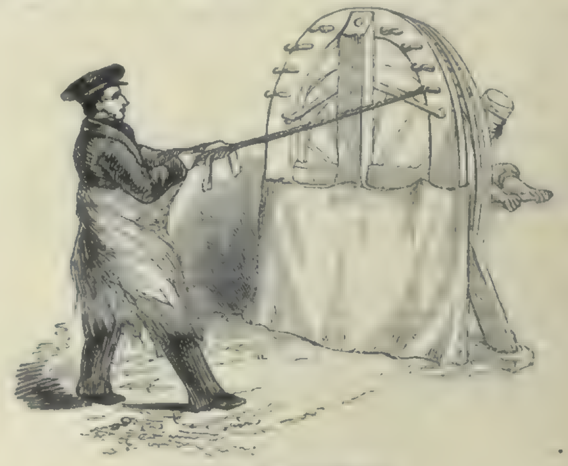

Fig. 2.—Rope-yarn Spinning.

The best mode of supplying the hemp is in the form of a thin flat skein. When the spinner has traversed the whole length of the rope-walk (or sooner, if the yarns are not required to be so long), another spinner detaches the yarn from the whirl, and gives it to a person who carries it aside to a reel; while the second spinner attaches his own hemp to the whirl-hook. The hemp, being dry and elastic, would instantly untwist if the yarn were now set at liberty. The first spinner therefore keeps fast hold of it all the while that the reeler winds it up, walking slowly up the walk, so as to keep the yarn equally tight all the way. When it is all wound up, the spinner holds it until another is ready to follow it on the reel. Sometimes, instead of being wound on a reel as they are made, the yarns are laid together in large hooks attached to posts at the side of the walk until about four hundred are collected together, when they are coiled up in a *haul* or skein, in which state they are ready for tarring.

The common size of rope-yarns is from one-twelfth to rather more than one-ninth of an inch diameter; 160 fathoms of white or untarred yarn weighing from two and a half to four pounds.

The next process is *warping* the yarns, or stretching them to a given length, in order that they may, when formed into a strand, bear the strain equally. When the rope is to be tarred, that operation is usually performed upon the yarns immediately after their being warped; as the application of tar to the yarns previous to their combination is necessary to the complete penetration of the whole substance of the rope. The most common method of tarring the yarns is to draw them in hauls or skeins through the tar-kettle by a capstan; but sometimes the yarns are passed singly through the tar, being wound off one reel on to another, and the superfluous tar being taken off by passing the yarn through a hole surrounded with spongy oakum. Great care is required in this process that the tar may boil neither too fast nor too slow, the common heat being from 212° to 250° Fahr. The degree of impregnation necessary depends on the kind of cordage; cables and water ropes needing a considerable quantity of tar, while for standing and running rigging it is sufficient that the yarns be well covered.

In making large cordage, it is not usual to twist together, at once, as many yarns as would suffice to form a rope of the required thickness; a suitable number of yarns, frequently from fifteen to twenty-five, are formed into a strand, and three or more such strands are afterwards combined into a rope. The twist of the strand is in an opposite direction to that of the yarns of which it is composed; in order that, as before mentioned, the tendency to untwist in the individual yarns may be counteracted, and taken advantage of to prevent the untwisting of the strand. In closing or laying the rope, three strands, or sometimes four, (in which case a small central strand or heart is added) are stretched at length along the walk and attached at one end to separate but contiguous hooks, and at the other to a single hook; and they are twisted together by turning the single hook in a direction contrary to that of the other three. A piece of wood called a *top* (see *fig.* 3), in the form of a truncated cone, is placed between the strands, and kept during the whole operation gently forced into the angle formed by the strands, where they are united by the closing or twisting of the rope. As the rope shortens in closing, one end only of the apparatus is fixed, the other being on a moveable sledge, whose motion up the ropewalk is capable of regulation by suitable tackle attached to it, or by loading it with weights. The top also is mounted on a sledge, for closing large cordage; and its rate of motion may be retarded, in order to give greater firmness to the twist of the rope. The art of the ropemaker, in this operation, consists in so regulating the various movements that the strands may receive separately at one end just as much twist as is taken out of them at the opposite end, by their twisting the contrary way in the process of combination.

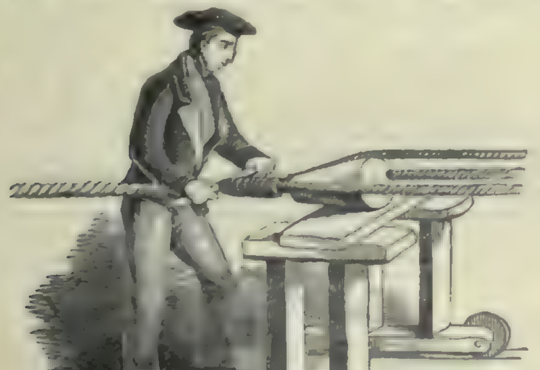

Fig. 3.—Laying a Rope.

Such is the method, more or less modified by the kind of machinery employed, of forming a *shroud-laid* or *hawser-laid* rope; and such appears to have been the whole process of rope-making until cordage of very large size was called for by the progress of navigation. In making such it was not found advisable to increase the number of yarns in a strand; it being difficult, when their number is very great, to throw an equal strain upon each, and thereby obtain their aggregate strength. To obviate this inconvenience, cables, or such large ropes as are said to be *cable-laid*, are formed by the combination of smaller ropes twisted round their common axis, just as shroud-laid ropes are composed of strands twisted round their common axis. As cable-laid ropes are harder and more compact than others, this mode of formation is adopted for ropes to be exposed to the action of water, even though their thickness may not be very great.

Ropes formed by plaiting instead of twisting are made use of for some purposes in which pliability is especially needed; they being more supple and less liable to entanglement than those of the ordinary make. Such ropes are preferred for sash-lines, clock-lines, &c., and generally where the rope has to pass over pulleys of small diameter.

Originally all the yarns composing a strand were selected of the same length. This arrangement was defective, as it is evident that when a number of yarns are stretched at length in a cylindrical mass, they will lie at different distances from the centre of the cylinder; so that, when twisted together, as all the yarns must form spirals of the same number of turns, those which are near the outside, forming spirals of large diameter, will be stretched to their full extent; while those near the centre, forming spirals of smaller diameter, will be less shortened by the process of twisting, and must therefore be more or less puckered up, according to their proximity to the centre of the mass. The first successful attempt to remedy this defect by varying the length of the yarns according to their position in the strand, was that under Captain Huddart's patent of 1793; since which time many further improvements have been effected in this essential point.

This brings us to notice briefly the application of machinery to rope-making, which may be said to have begun about the year 1783, and to have been the subject of numerous ingenious inventions since that date. One series of machines relates to the combining of the hempen fibres into yarns; another to the twisting of yarns into ropes; while the more complex kinds include both of these actions. Mr. Lang, of Greenock, was the first to produce successfully machine-spun yarns, intended to get rid of the irregularities and defects of those formed by hand. By his process the hemp is more completely heckled, or divided into fibres, than in the common mode of proceeding; and the advantage of each fibre being laid at full length in the yarn, instead of being doubled, as in hand-spinning, is ensured. By a modification of the usual process, the fibres of hand-spun yarns may be laid in at full length, instead of being doubled, as when they enter the yarn by their bight; but experiment has not shown any great advantage from such a mode of spinning. That some improvement in this operation was needful, may be inferred from the result of a comparison between Mr. Lang's machine-spun yarns and those of equal grist spun by hand; the result showing the strength of the former to exceed the latter by fifty-five per cent. Mr. Sherman, of Liverpool, patented a method of rope-making intended to obviate the necessity for a long shed or rope-walk. The machinery comprises rotating tables with hollow shafts or axes; spindles project from the surfaces of the tables; bobbins are mounted on the spindles; and hemp is wound on the bobbins. The number of bobbins depends on the number of yarns and strands. The ends of the yarns are passed through holes in a draw-plate beyond the hollow shaft of one table, then through the hollow shaft, then through another shaft; and so on. The yarn from each bobbin thus becomes twisted round that of the other bobbins on the same table; then round the similarly twisted strands of another series; and then of a third. The finished strand or rope is drawn from the tube of the last table, and is wound upon a reel ready for use. A modification of this planetary system, as the inventor calls it, suffices for twisting the strands into a rope.

Captain Huddart's rope-making machinery, above adverted to, is very ingenious. In order to get rid of the unequal strain upon the exterior and interior of a rope, Huddart saw that the outer yarns of every strand ought to be somewhat longer than the inner, to compensate for the greater circumference round which they have to turn. This he accomplished in a beautiful way. Bobbins are arranged in a skeleton frame, each poised on a pivot and loaded with yarn; the number of bobbins depends on the thickness of the strands to be made. The ends of all the yarns are passed through an equal number of small holes in a plate, and combined into one close group, which is slightly compressed by passing through a tube, and then wound on a reel. The mechanism between the plate and the reel rotates on a horizontal axis, thereby imparting a twist to the assemblage of yarns. The free rotation of the bobbins, the arrangement of the holes in the plate, the position of the tube, and the velocity of revolution—all combine to produce a strand of any desired hardness of twist, without undue strain upon any of the yarns. The strand thus produced is a smooth uniform piece of cordage, varying in thickness according to the size of the rope to be made; for a 12-inch cable, the strand is about an inch thick and contains 80 yarns. Being worked by steam power and having facilities for renewing the bobbins as they are exhausted, this machine can produce a rope any length.

The strength of twisted cordage has been made the subject of numerous experiments. Réaumur, early in the last century, found that a well-made small hempen cord broke in different places with 58, 63, 67, and 72 lbs., its mean breaking weight being 65 lbs.; while the three strands of which it was composed bore 29¼, 33¾, and 35 lbs. respectively; so that the united absolute strength of the strands was 98 lbs., although the average real strength of the rope was only 65 lbs., showing a loss of strength from twisting equal to 33 lbs. It appears that the cord used by Réaumur was of very unequal quality, as another portion of it broke with 72 lbs., while its strands bore separately 26, 28, and 30 lbs.; which shows the diminution of strength from twisting to have been from 84 to 72 lbs., the loss being in this instance only 12 lbs. The later experiments of Sir Charles Knowles indicates a diminution of strength nearly equal in amount to the first-mentioned of Réaumur. He found a white or untarred rope of 3¾ inches in circumference break, on an average of several trials, with 4552 lbs.; while the aggregate strength of its yarns, which were 72 in number, and bore on an average 90 lbs. each, was 6480 lbs.; the loss being equal to 1928 lbs., or about 30 per cent. Duhamel endeavoured to ascertain what degree of twist would produce the most useful effect. He caused some ropes to be made, so that only one-fourth of the length of the yarns was absorbed in twisting, instead of the usual proportion of one-third. These ropes were tried in shipping, and found to be lighter, thinner, and more pliant than those of the ordinary make. The following statement shows the comparative strength of ropes formed of the same hemp, and the same weight per fathom, but twisted respectively to two-thirds, three-fourths, and four-fifths of the length of their component yarns :—

Degree of twist.	Weight borne in two experiments.	
⅔	4098 lbs.	4250 lbs.
¾	4850	6753
⅘	6205	7397

The result of these experiments led Duhamel to try the practicability of making ropes without any twist, the yarns being wrapped round to keep them together. These had great strength, but very little durability, the outer covering soon wearing off, or opening at bendings, so as to admit water, and occasion the rope to rot. But while such untwisted skeins of rope-yarns, or *salvages*, are unfit for most of the purposes to which cordage is applied, they are used with advantage for the tackle of great guns and some other purposes for which the greatest strength and pliancy are required. The usual reduction of length by twisting is one-third; this applies to *shroud* or *hawser*-laid ropes; those which are *cable*-laid are further shortened, so that 200 fathoms of yarn are required to make 120 fathoms of cable. Ropes formed in the common manner, with three strands, do not require a *heart*, or central strand; because the angles formed by the union of the three cylindrical strands are so obtuse that the pressure of the operation of laying or closing the rope causes the strands to fill them up completely; but when the number of strands exceeds three, a heart is essential to keep them equidistant from the axis of the rope, and to fill up the vacuity that would otherwise be left by their not meeting in the centre. The heart can however add very little to the strength of the rope; as its fibres lie much straighter than those of the outer strands, and, not being able to extend with them when the rope is stretched, are soon pulled asunder. The following simple rule for calculating the strength of ropes is given by Robison:—Multiply the circumference of the rope in inches by itself, and the fifth part of the product will express the number of tons the rope will carry. For example, if the rope be 6 inches in circumference, 6 × 6 = 36, the fifth of which is 7⅕, the number of tons which such a rope will sustain. The following rules for calculating the *weight* of cordage may also prove useful:—To find the weight of shroud or hawser-laid rope, multiply the circumference in inches by itself, then multiply the product by the length of the rope in fathoms, and divide by 420, the product will be the weight in cwts. Example: to find the weight of a 6-inch hawser-laid rope, 120 fathoms long, 6 × 6 = 36 × 120 = 4320, which, divided by 420 gives the weight of the rope, 10 cwt. 1 qr. 4 lbs. Again: to find the weight of cable-laid cordage, multiply its circumference in inches by itself, and divide by 4. The product will be the weight, in cwts., of a cable 120 fathoms long; from which the weight of any other length may be readily deduced. Example: required the weight of a 12-inch cable, 120 fathoms long; 12 × 12 = 144, divide by 4, and the product, 36, is the weight in cwts.

Mr. Chapman, master ropemaker at Deptford Dockyard, in a treatise recently published on this subject, gives the following names, lengths, and weights of certain kinds of rope or line as usually made in England :—

Kinds.	Length.	Weight.
Deep sea lines	120 fathoms	36 lbs.
,,	,,	34
,,	,,	32
,,	,,	28
Hand lead lines	20	4
Hambro' lines, 12 threads . . .	28	3
,, 9 ,,	,,	2¼
,, 6 ,,	,,	1½
Fishing lines	25	1
,,	,,	¾
,,	,,	½
,,	,,	¼
Samson lines	30	1½
,,	,,	1¼
,,	,,	1
,,	,,	¾
Log lines	25	1 to 3
Marline	12 skeins	4
Sewing twine	24 ,,	8 to 9
Reefing twine	24 ,,	8 to 9

Much of the cordage used on shipboard requires the process of *serving* before it is fitted for its work. This consists in binding a smaller rope very tightly round a larger one, to preserve it from rotting after friction. It is done as shown in *fig.* 4, where a horizontally-stretched rope is being "served" or covered with spun yarns. A mallet, having a concave groove on the side furthest from the handle, is laid on the rope; two or three turns of spun yarn are passed tightly round the rope and round the body of the mallet. A boy passes a ball of yarn continually round the rope; while a man winds it on by means of the mallet, the handle of which serves as a lever to enable him to strain every turn as tightly as possible. The yarn thus appears like a screw whose threads pass almost transversely round the rope.

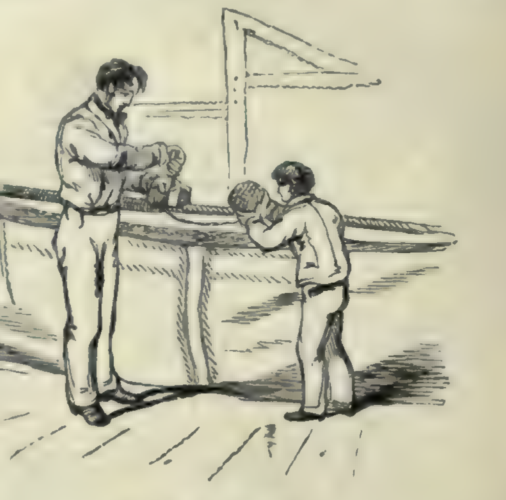

Fig. 4.—Serving a Rope.

All the ropes hitherto described are round or cylindrical; but *flat* ropes are also made, chiefly for mining purposes. They are either formed of two or more small ropes placed side by side, and united by sewing, lapping, or interlacing with thread or smaller ropes; or of a number of strands of shroud-laid rope similarly united. In either case it is necessary that the component ropes or strands be alternately of a right-hand and left-hand twist, that the rope may remain in a quiescent state. The latter method of making flat ropes was first patented by Mr. Chapman, in 1807; and he considered it to afford the strongest possible combination of rope-yarns, his belts or flat ropes appearing to be even stronger than *salvages* (which are skeins of rope-yarns without any twist) of the same number of yarns. This seeming inconsistency is occasioned by the imperfection of hand-spun yarns; because if each

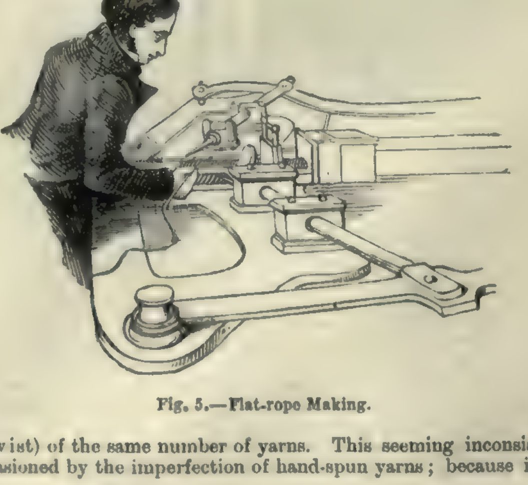

Fig. 5.—Flat-rope Making.

yarn bears its own strain unaided, it will break at its weakest part; whereas, if combined, the mean strength of each will be rendered available. Huddart's flat-rope machine, of more recent invention, is shown in part in *fig. 5*. Supposing four round ropes be needed to make one flat rope, four reels are so placed that the ropes can unwind from them with facility, and pass side by side through a steam-heated box, where the tar becomes a little softened, and the ropes more easily worked. They next pass through a groove or recess closed in tightly at top, bottom, and sides, except holes at the sides to admit large needles. A piercer, or sharp-pointed rod of steel, is then forced entirely through the whole of the four ropes, by leverage produced by steam power; and a man immediately passes a needle and thread through the hole. Two piercers are employed alternately, one on either edge, making holes as fast as two men can introduce needles and thread. The thread here spoken of is sometimes yarn as much as half an inch in thickness, requiring great force to draw it tightly.

Much attention has been devoted to the discovery of the best method of preserving ropes from decay, especially when exposed to the action of water. The operation of tarring, which has been almost universally practised for this purpose, effects it very imperfectly, and materially diminishes the strength of the cordage. Taking the mean of several experiments by Duhamel, it seems that untarred ropes bore a greater weight, by nearly 30 per cent, than those to which the tarring process had been applied; and he states that it is decided by experience that white cordage in continual service is one-third more durable than tarred, that it retains its force much longer when kept in store, and that it resists the ordinary injuries of the weather one fourth longer. Notwithstanding these facts, it is found that for cables and ground tackle, which are much exposed to the alternate action of water and air, tarring is a valuable preservative; though cordage that is only superficially tarred is said to be stronger than such as is tarred throughout, and better able to bear the alternations of wet and dry. The removal of the defects and bad qualities of common tar was the object of a patent taken out by Mr. Chapman. Unsuccessful attempts had been made to substitute oils and various fat substances, which would be insoluble in water, for tar; but they had been found to impede the operation of twisting. Chapman improved the ordinary tar, first, "by boiling the tar in water one or more times, each of which extracts a portion of its superabundant acid, and its mucilage, which contains a disengaged acid;" and, secondly, "by continuing these processes until the tar has thrown off a larger portion of its essential oil, and becomes more pitchy than usual; and, finally, by restoring the requisite plasticity through the addition of substances less injurious and less volatile, and therefore more continuous: namely, by the addition of suet, tallow, animal oils, or suitable expressed oils." Of the advantages attending this process, an idea may be formed from the subjoined statement of the relative strength of the cordage without any tar, with common tar, and with Chapman's purified tar. The rope contained twelve yarns in each strand; part was tried immediately, and the rest steeped in water for about three months, then removed to a foundry stove for three months, and finally kept at the ropery nine months; when another trial gave the following results:—

Description of Rope.	Portion of original strength retained.
White	5·7 per cent.
Common tarred	33·6 "
Tarred with purified tar	43·8

Sir Joseph Banks had some ropes tarred with *teak* tar, by way of experiment, and found them to be one-third stronger than those done with common tar. Tanning has been tried for the preservation of ropes, but apparently without realising any decided advantage. The solution employed in kyanising, and a solution of caoutchouc, have also been tried as preservatives; but common tar still continues to be the chief substance used for this purpose.

Mr. Chapman gives the following notice of the mode of classifying the work in her majesty's dockyards. Petersburg hemp is mostly used for cables and cablets; Italian hemp for bolt rope and breechings; and Riga hemp for all other cordage. To make Petersburg hemp into No. 20's, the hemp is given to the hatcheller in bundles of 70 lbs.; he takes out 7 lbs. of shorts, and gives 63 lbs. of heckled hemp to the spinner, who spins it into 18 threads of 170 fathoms and 3½ lbs. each. To make Riga hemp into No. 25's, the hemp is given to the hatcheller in bundles of 56 lbs.; he takes out 5 lbs. of shorts, and gives 51 lbs. of heckled hemp to the spinner, who spins 18 threads of 170 fathoms and 2⅚ lbs. each. In using Italian hemp, 16 lbs. of shorts are taken out of 112 lbs of hemp; and the remaining 96 lbs. are made up into bands of 1¾ to 3½ lbs. each, according to the size of the yarns to be made. Much old-fashioned routine still prevails in the royal dockyards, in defining exactly how many porters, parters, hatchellers, wheelturners, spinners, &c., shall be employed for each ton of hemp.

We have hitherto spoken only of hemp as the material employed; but several other kinds of vegetable fibre have been made use of in the manufacture of cordage; and some appear greatly to exceed hemp in strength. In a comparative trial made at Paris between ropes made of hemp and of the aloe from Algiers, the latter was found to bear 2000 kilogrammes, while the former, of equal size, bore only 400. Ropes have been formed also of long wool; but they are only about one-third as strong as the best hempen cordage of the same size. Ropes composed of fibres of hemp intermixed with threads of caoutchouc are very valuable for some purposes, owing to their superior strength and elasticity. Their power of bearing sudden jerks without injury is a highly important property. Such a rope was used with the grapnel or anchor of the great Nassau balloon, and was found to arrest the balloon without any unpleasant check when the grapnel caught. Ropes made of thongs of ox-hide twisted together are used in the rope-bridges of Peru, and for some other purposes. Coir or cocoa-nut fibre has lately been much used for this purpose, owing to the high price of Russian hemp; it wears well, weighs little, and is cheap; and is useful for hawsers and warps owing to its great elasticity.

Wire Ropes.—Iron is the substitute which is now engaging most attention. Ropes formed of this metal are found to effect a great saving of expense from their durability and superior lightness. From a paper communicated by Count Breunner to the British Association in 1838, it appears that such ropes had been introduced about seven years before, in the silver mines of the Harz Mountains, and had been found so advantageous as almost entirely to supersede flat and round ropes of hemp in the mines of Hungary, and most of those in the Austrian dominions. The count observes that these iron ropes are nearly equal in strength to solid bars of the same diameter, and equal to hempen ropes of four times their weight. One of them had been in use for upwards of two years without any perceptible wear, though a common flat rope performing the same work would not have lasted much more than one year. The diameter of the largest rope in ordinary use is one inch and a half, and it is composed of three strands, each containing five wires. Great care is observed in the manufacture of these ropes, that the ends of the wires may be set deep in the interior of the rope, and that two ends may not occur near the same part. In use, it is necessary that the ropes be wound on a cylinder of not less than eight feet diameter, and be kept well coated with tar, to prevent oxidation. In one case mentioned by Count Breunner, so great a saving of power was effected, that four horses were doing as much work with a wire rope as six with a flat hempen rope.

Prior to the date of this memoir, patents had been obtained in this country for the manufacture of wire ropes; and they have since been improved and acted upon. The wire ropes of Mr. Andrew Smith are formed in various ways, according to their intended use. For standing rigging straight untwisted wires are employed, bound round with cloth or small hempen cordage saturated with a solution of caoutchouc, asphaltum, or other preservative from rust. Flat ropes may likewise be made of straight wires, interwoven or wrapped with hempen yarn, or sewed between canvas, &c.; but the patentee prefers using them with a slight twist. Other ropes are formed much in the same way as those of hemp; the wires taking the place of rope-yarns, and being twisted into strands, and combined into ropes, both hawser-laid and cable-laid. The twisting should not be so hard as in hempen cordage; and all the wires must be protected by an anti-corrosive composition, or by coating with tin, zinc, &c. In a patent obtained by Mr. Newall of Dundee, for improvements in wire ropes, coating with the following mixture is recommended:—Tar, six parts; linseed oil, two parts; and tallow, one part: the whole being melted together, and applied while hot. In this patent it is proposed to twist wires round a core, either of wire, hemp cord, spun yarn, or other material, to form a strand; and to lay such strands round a similar core when there are more than three strands in a rope. For joining the wires, Messrs. Smith and Newall both recommend twisting their ends together for a few inches; and the latter also suggests the possibility in some cases, of welding them. Wire ropes may be very conveniently and firmly secured at their ends by passing them through the small end of a conical collar, and doubling up, or *upsetting*, the ends of the wires, which may then be welded into a solid mass, or secured by running melted brass or solder among them. The collars may then be attached, in various ways, to anything with which it is desired to connect the rope; or they may, as suggested in Newall's patent, be screwed together, so as to unite several lengths of rope. Iron is the material usually employed for wire ropes, but copper and other metals may also be used. The annexed table, showing the comparative size and weight per fathom for equal strength, gives the result of experiments with the wire ropes of Mr. Andrew Smith, and may serve to show their great superiority to those of hemp, which they surpass even in flexibility:—

Hemp Rope.			Patent Wire Rope.			Equal to a strain of	
Size.	Weight per fathom.		Size.	Weight per fathom.			
Inches.	lbs.	oz.	Inches.	lbs.	oz.	tons.	cwts.
3	2	4	1¼	1	4	2	10
4	3	15	1½	1	9	3	10
5	6	0	1¾	1	14	6	15
6	9	0	2	2	2	8	0
7	12	3	2¼	2	9	8	11
8	14	5	2½	4	1	9	18
9	19	6	3	5	4	15	6
10	25	0	3½	7	1	24	6
11	30	0	4	11	6	29	5
12	36	5	4½	15	12	35	4

Experiments were made at Liverpool in 1857, to find the relative strength of hempen rope and wire rope for the standing rigging of ships, as determined by the corporation testing machine at King's Dock. All the ropes were made by Messrs Garnock and Bibby, with equal care. The following results were obtained :—

3	inch galvanised iron wire rope bore a strain of . .	20 tons.
3	inch Manilla hemp rope ,, . . .	5
3	inch Russia hemp rope ,, . .	4
3	inch galvanised iron wire rope ,, . . .	16
3	,, ,, ,, . . .	8

The advantage of iron is here very obvious; indeed this metal is found to be, for a given strength, less heavy, less bulky, one-fourth cheaper, and less affected by the atmosphere, than hemp. Soft wire makes the most pliable rope for splicing; but hard wire is stronger. Three-fourths of all the ships now rigged at Liverpool are provided with iron wire standing rigging.

Some of the machines for making wire rope act in the following way. The wire is wound in bobbins mounted in frames set on the periphery of a larger frame like a cage. The cage revolves round an axis, on the bottom of which is a fixed spur-wheel; and the lower end of the vertical axis of each bobbin-frame carries a spur-wheel gearing into this. There is thus obtained a sort of 'sun-and-planet' motion, the cage carrying the bobbin round the central axis, and each bobbin-frame revolving also on its own axis. The wires, in their progress from the bobbins, pass through holes in the top of the central axis, and are there united to form the strand or rope. In Mr. Newall's patent of 1857, the strand-wire for electric cables is drawn through dies or between rollers after the twisting, to bring it to a close cylindrical form, and thereby aid the electric conduction.

The demand for wire rope being now very extensive, for shipping and for telegraphic cables, the patents are or have been regarded as valuable property. Mr. Newall's first patent, which expired in 1854, was a subject of many legal contests, arising out of infringements.

ROPES, RIGIDITY OF. [RIGIDITY OF ROPES.]

ROSA. *Medical Properties of.* Of the numerous species or varieties of this genus, three only are indicated in the 'Pharmacopœia' as the sources of the officinal articles; but a very considerable number of them contribute the different materials. Those indicated in the 'Pharmacopœia' are: the *Rosa canina*, or common dog-rose; *Rosa gallica*, the French or red rose; and *Rosa centifolia*, the hundred-leaved or cabbage-rose. Of the first, the so-called fruit (hips) is the officinal part. This is truly the enlarged persistent calyx, enclosing the real fruits, which are numerous small achenia, clothed, as well as the inside of the calyx, with silky hairs. The hairs and achenia are to be carefully removed, and the fleshy calyx beaten into a pulp, to which gradually thrice their own weight of white sugar is to be added. The employment of heat in the preparation of this conserve, though directed by the 'Pharmacopœia,' is better omitted. The pulp consists chiefly of malic and citric acids, in combination mostly with some salts, tannin, resins, a small quantity of volatile and fixed oils, fibre, and a large quantity of sugar. The action on the stomach is slightly refrigerant and aperient, its sweetness recommending it to children, and as a vehicle for other medicines. It is apt to candy or concrete by keeping. The fresh hips, freed from the fruits and hairs, bruised, and having a little sugar added, yield, by pouring warm water upon them, a cooling mildly astringent drink, which would be grateful to the poor suffering from autumnal fevers.

The petals of both the *Rosa gallica* and *R. damascena* are supplied to herbalists for medical and chemical purposes. The latter is most extensively cultivated at Mitcham for the London market. The buds are collected before they expand, and the calyx and lower part of the petals, termed claws, being cut off, they are quickly dried. If this last process be conducted slowly, it impairs both their astringency and fine Modena colour. Their astringency and odour are greatest when collected before the process of anthesis, or bursting of the anthers. About 2000 flowers yield 100 lbs. of fresh petals, which when dry weigh only 10 lbs. After drying the odour is faint, the taste bitter and astringent. As by exposure to the light and air they lose their fine colour, and soon become mouldy or worm-eaten, they must be carefully preserved in well-stopped bottles or canisters.

According to the analysis of Cartier, they consist of volatile oil, colouring matter, fatty matter, gallic acid, tannin, albumen, soluble salts of potash, insoluble salts of lime, silica, and oxide of iron. The tannic and gallic acids are the cause of the astringency, and also of the dark colour, which results on adding a solution of any salt of iron to an infusion of roses, and of a slight precipitate when a solution of gelatine is added to the infusion. The property of forming a black compound with iron is taken advantage of by beating the petals with cloves and other spices in an iron mortar, till a thick black paste is formed, which hardens on exposure to the air, and is then polished or turned, so as to form the perfumed beads for necklaces or rosaries. The petals of R. centifolia are often preferred. The exact nature of the colouring principle has not been ascertained, but it is not owing to oxide of iron, as the quantity of iron is much greater in white than red roses, Cartier having obtained from 1000 grains of white roses 99 grains of ashes, containing 12·4 of iron, while a similar quantity of red roses yielded only 50 grains of ashes, containing only 4 grains of iron.

The petals of the *Rosa damascena* are the most laxative, except perhaps the *R. semperflorens*, but it is seldom that they are used as aperients, though the petals of the *R. gallica* are formed into a confection which has the advantage over that of the *R. canina*, inasmuch as it neither candies nor becomes mouldy. In forming this or the other preparations, a stone (not an iron) mortar must be used. The chief employment of the conserve of the Gallic rose is as a vehicle for other medicines and as the basis of blue pill.

The infusion of roses is made by pouring boiling distilled water on the petals, and adding dilute sulphuric acid, which are allowed to macerate for six hours, and when strained, refined sugar is to be added. The vessel in which this process is conducted should not be glazed with lead. By this means is obtained an elegant, fragrant, and mildly astringent tonic and refrigerant liquid, which is of great utility, either alone, especially to check the wasting perspirations of consumption, or as a vehicle for most salts which are formed with sulphuric acid. It is likewise employed as a gargle, alone, or with various adjuncts, one of the best of which is the mel rosarum, or honey of roses, made with the petals of this kind of rose. A syrup is sometimes made with them, which is only used to sweeten and colour other medicines.

The *Rosa centifolia*, hundred-leaved rose, especially the variety of it termed the *Provence* or *cabbage rose*, is cultivated both on account of its exquisite perfume and the uses to which it, with its products, can be applied. The petals are the officinal article. They are directed to be collected when the flower is full blown; and to be plucked off, not allowed to fall off. It is better to collect them before the flower is fully expanded, as the odour rapidly diminishes as the anthesis proceeds; 100 parts dry into 18 only. They are to be dried in the open air, and not in an oven, as desiccation impairs their fragrance, while it heightens that of the *R. gallica*. Their odour is said to be singularly exalted by iodine. When dried, they are of a pale red, with a faint rose odour, and an astringent taste. They easily part with their colour, and are therefore to be protected from air and light: if salted, they may be preserved unimpaired for years. With the addition of salt, pepper, and cloves, they are used to form the rose-pots which adorn the apartments of the rich, but which may equally be made to contribute to the enjoyment of the poor, as the expense of this perpetual feast is so small as not to be felt by the poorest occupier of a room. The colouring matter extracted by alcohol furnishes a most delicate test for the presence of alkalies.

A syrup is also made of this sort, but the chief use of it in England and France is to yield by distillation rose-water, the medical properties of which are too slight to merit further notice here. That to which spirit of wine has been added is unfit for medical purposes. In hot countries a large quantity of volatile oil is elaborated by the flowers of this and several other species, such as the *Rosa moschata*, *Rosa damascena*, and in Italy the *Rosa sempervirens*, which constitutes the *athar*, *ather*, *attar*, *utter*, or *otto* of roses. [ATTAR OF ROSES.]

(Pereira's *Materia Medica.*)

ROSARY. [BEADS.]

ROSE, *Culture of the.* To obtain roses in their full perfection they require a situation open to the south, and free from buildings, trees, and the effects of smoke. They must also be sheltered from the wind. The tenderer sorts should be trained on a wall; the hardier dwarfs in beds or on the lawn, and standards arranged in lines along the walks. In planting, care should be taken to give room for the roots. A hole three feet in diameter and two feet deep should be filled with rich loamy soil, or a mixture of leaf mould, or rotted cow or pig manure, the straggling rootlets removed, and the plant be fixed in the centre, supported by a stake to prevent it being loosened by the wind. November and December are the general months for planting, but February is perhaps better in moist soils if the holes are made previously and exposed to a winter's frost. Standards should be at least three feet apart, dwarfs may be one-third closer. When planting in pots, the same soil should be prepared, taking care to have the bottom of the pot well supplied with broken crocks, and, to ensure sufficient drainage, the hole for the pot should be made of such a size and such a depth, that on pressing the pot into it, till about an inch below the surface, it may drive some of the side soil down so as to form a shoulder, and leave a vacancy of an inch or two below the pot. This not only ensures drainage, as the plant requires good watering, but is less likely to attract the roots to the adjacent soil. Roses are all the better for such surface-manuring during the autumn, either with compost of night-soil, or guano and wood ashes.

In raising roses from seed, the hips, gathered when quite ripe, should be kept dry and whole till February, then broken and sown in a seed-pan about 8 or 9 inches deep, filled with rotten manure mixed with sandy loam or peat, covering the seed with about half an inch of the mould. Care must be taken to guard the seed from the attacks of mice; this is best done by covering with a wire web, which also preserves the pan moist. Water occasionally, and the young plants will begin to appear in April or May. After having made three or four leaves, pot them in small pots, and in about a month they will be fit to remove to the border; and the free-growers by August will have made shoots sufficient to take buds from. The stocks must be cut down and budded, and they will then flower in the following summer if left unpruned.

Summer and autumnal roses are propagated by layers, cuttings, budding, and grafting. These operations are the same for the rose as for many other plants, and the budding is performed with even more facility than with many other plants, as the bark opens and closes firmly. Strong plants are also raised by budding on the roots, which are divided from the parent stem, and by this practice a year is gained for bushes flowering on their own roots.

The usual stock for grafting on is the common briar; but almost any rose of a hardy nature will afford stocks for a more valued variety, where the stocks are not required of a great height for standards, and one of the most favoured is the Minetti, a variety introduced from Italy, which has the advantage of not throwing up suckers. Of other roses, from which stocks are wished for, the suckers may be allowed to spring. The forcing of roses for early show or for the greenhouse depends on the same principles as other plants—a somewhat earlier budding, protection from cold, and moderate heat applied in the early spring.

The varieties are now almost endless, and every season produces new ones. All the chief families are mentioned under Rosa, in the Nat. Hist. Div., and a list of the principal varieties will be found in Rivers's 'Rose Amateur's Guide,' last edition.

ROSE ENGINE TURNING. [Turning.]

ROSEO-CHROME. [Chromium.]

ROSEO-COBALTIN. [Cobalt. *Ammoniacal Compounds of Cobalt.*]

ROSETTA STONE is the name given to a stone in the British Museum, which was originally found by the French in 1799 among the ruins of Fort St. Julien, which is near the Rosetta mouth of the Nile. It was delivered up to the British on the capitulation of Alexandria, and was brought to England in the year 1802. This stone, which is a piece of black basalt, contains parts of three distinct inscriptions: the highest on the stone is in what we generally call hieroglyphic; the second is in that character commonly called the "enchorial," or "the characters of the country;" and the third, which is in Greek, declares, at the end, that the decree which this stone contains was cut in three different characters, the "sacred characters," "those of the country" or the "enchorial," and the "Greek." In its present state the stone is much mutilated, chiefly at the top and at the right side. Its greatest length, in its present condition, is about three feet, measured on the flat surface which contains the writing; its breadth, which in some parts is entire, is about two feet five inches. A large part of the hieroglyphic inscription is broken off, but it probably contained in its entire state about twenty or at the utmost twenty-one lines; the enchorial or second inscription consists of thirty-two lines, but the beginning of the first fifteen lines are wanting, and the Greek text contained, when entire, fifty-four lines, but the end of it is at present mutilated. We learn from the Greek text that the Rosetta stone was erected in the reign of Ptolemy V., Epiphanes, and probably about B.C. 196. Epiphanes succeeded to the throne on the death of his father Philopator, B.C. 205, when he was a child only four or five years old. In this monument the acts done during the prince's minority are attributed to him, and he is commended for his piety, his liberality to the temples, his remission of the arrears of taxes and diminution of the imposts, his victories over the rebels, and his protection of the lands by dams against the inundations of the Nile.

It appears to have been placed in a temple dedicated by Necho to the god Tcum, the setting sun. The Rosetta stone was the key to the interpretation to the hieroglyphs, the first attempts of De Sacy to decipher the demotic or enchorial having been followed by the more successful results of Young and Champollion, in deciphering the hieroglyphic text. Lately a critical translation of the hieroglyphical portion has been made by M. Brugsch.

A critical examination and restorations of the Greek text have been made by Ameilhon, Heyne, Villoison, Drumann, Porson, and Letronne. The enchorial text has been also published and translated by Young and Brugsch. As the inscriptions are paraphrases and not literal translations, and the hieroglyphical portion is much mutilated, it does not add a great deal to the hieroglyphical vocabulary. [Hieroglyphics.] (Brugsch. H., 'Die Inschrift von Rosette,' fo. Berlin, 1850; 'Inscriptio Rosettana,' 4to, Berlin, 1851; Letronne, 'Inscription Grecque de Rosette,' 8vo, Paris, 1840.)

ROSICRUCIANS is the name of a secret society whose existence became first known to the public in the 17th century, by means of several publications which have been attributed to John Valentine Andreæ, a German scholar, born at Herrenberg, in the duchy of Würtemberg, in 1586, who, after studying at Tubingen, became a minister of the Lutheran church, and in course of time was made almoner of the Duke of Würtemberg and abbot of Adelberg. Andreæ died in 1654. He was a man of a mystical turn of mind, who had conceived the idea of effecting a general reform of mankind. He wrote many works, chiefly on mystic subjects. It is doubtful, however, whether those particular works which would establish his connection with the Rosicrucian Society are really his. The following are the titles of three of his works:—1. 'Eleucidarius Major, über die Reformation der ganzen weiten Welt, F. C. R. aus ihren chymischen Hochzeit,' 1617, in which there is a mixture of precepts of alchemy with maxims of ethics. 2. 'Fama Fraternitatis des löblichen Ordens des Rosenkreuzes,' Frankfort, 1617, in which there is a story of a certain Christian Rosenkreuz, a German noble of the 14th century, who, after travelling long in the East, returned to Germany, and there established a fraternity, or secret society, of a few adepts, under certain regulations, living together in a building which he raised under the name of Sancti Spiritus, where he died, at 106 years of age. The place of his burial was kept a profound secret by the adepts, and the society renewed itself by the admission of successive new members in silence and obscurity, according to the last injunction of its founder, who directed the following inscription to be placed on a door of Sancti Spiritus:—"Post CXX. annos patebo." 3. 'Confessio Fraternitatis Rosese Crucis ad Eruditos Europæ,' which is appended to the preceding, and in which it is stated that the order does not interfere with the religion or polity of states, but only seeks for the true philosophy; that many absurd fables have been told of the fraternity, either by its enemies or by fantastic people. It states also that once a year the members are to meet at appointed places to converse together upon secret matters, and that new members are to be admitted to supply the place of those who are deceased, and to work for the common purpose of the order, giving no clue however for discovering what that purpose was. In fact the secret, if secret there was, has been effectually kept to the present day. The Rosicrucians have not been heard of as a separate order for a century past; but some have thought that they continued to exist under the name of the Illuminati, who were much talked of in Germany and France in the latter part of the 18th century; and a connection has been supposed by some writers to exist between the Rosicrucians and the Templars and Freemasons. The reader who wishes to investigate this obscure subject may consult F. Nicolai, 'On the Crimes ascribed to the Templars;' Chr. Murr, 'On the True Origin of the Rosicrucians,' 1803; and J. G. Buhle, 'Ueber den Ursprung und die vornehmsten Schicksale der Orden der Rosenkreuzer und Freymaurer,' Göttingen, 1804.

ROSIN. [Resins.]

ROSMARI'NUS OFFICINA'LIS, *Rosemary*, a term which is apt to lead to the confounding of Rosemary with the Ledum palustre or wild marsh-rosemary, which has very different and even dangerous properties. Genuine rosemary is a shrub, a native of the south of Europe, Asia Minor, and China. To the bees feeding on the flowers, the flavour of Narbonne honey is said to be owing. The officinal part is the top or upper part of the twigs. The flowers were termed *Anthos*, being so highly esteemed, as if it were the flower of flowers. This name it is necessary to know, as many of the earlier preparations come under it, rather than under rosmarinus. The leaves are about an inch long, linear, slightly revolute at the margins, dark green and reticulate on the upper surface, hoary and white on the under. The leaves and calyces of the flowers have a strong, penetrating, aromatic odour, which is rendered stronger by bruising them; and a bitter, burning, camphor-like taste. They owe this to the presence of tannic acid, bitter matter, perhaps resin, and especially to a volatile oil, of which one drachm may, by distillation, be obtained from one pound of the leaves.

Oil of rosemary (Oleum Rorismarini, or Ol. Anthos) is chiefly prepared in Spain and the south of France, by distillation of the leaves and flowers. At first it is nearly transparent and very limpid, but by time it becomes both yellowish and thicker. It possesses the strong penetrating odour of rosemary, with a camphor-like intermixture, and a burning taste. It has an acid re-action. The specific gravity varies with the purity and age of the specimen; it is commonly 0·91, but by rectification with alcohol it is brought to 0·89 or 0·85. It mixes with alcohol of ·83 in every proportion. By shaking with potass, or by the evaporation and absorption of oxygen which time effects, it deposits a stearopten, or rosemary-camphor, to the extent of a tenth part. Hydrochloric acid gas blackens it, but does not form an artificial camphor. With iodine it partially explodes.

The oil of rosemary of commerce is an artificial preparation of oil of turpentine distilled with rosemary; it is also adulterated with spike oil, obtained from the Lavandula Spica. This may always be distinguished from the genuine by not reddening litmus-paper.

Rosemary possesses valuable stimulant and carminative properties; but it is chiefly employed as a perfume, entering into the composition of the Queen of Hungary's Water, Eau de Cologne, and aromatic vinegar. Properly diluted it forms a useful evaporating lotion. It is also used in preparations for promoting the growth of hair and preventing baldness.

ROSOLIC ACID was discovered by Runge in 1834, and was so called from the rosy-red colour of its salts. It is formed occasionally in gas works when Carbolic Acid is exposed to the air in contact with lime. Rosolic acid may be artificially prepared by heating together a mixture of manganate of soda and crude carbolic acid. On decomposing the dark red rosolate of soda by hydrochloric acid, the rosolic acid is precipitated in resinous flakes which unite to an amorphous mass.

Pure rosolic acid is a dark green lustrous resin. Its powder is of a bright red colour, soluble in ether, alcohol, creasote, the alkalies, and in concentrated acids. Its acid characters are very feeble, and its compounds unstable. Were it less fugitive it would be valuable as a dyeing agent.

Rosolic acid has lately been examined by Hugo Müller and by Angus Smith, with the following results in regard to per-centage composition:—

	Smith.	Müller.
Carbon	70·837	75·92
Hydrogen	5·814	5·83
Oxygen	23·349	18·25
	100·000	100·000

At present the data are insufficient for the calculation of its formula.

ROSTRUM, or, more properly, ROSTRA, was a platform or elevated space of ground in the Roman forum, from which the orators used to address the people, and which derived its name from the circumstance that after the conquest of Latium the beaks (rostra) of the Antiatian ships were affixed to the front of it. (Liv., viii. 14.) The rostra was between the Comitium, or place of assembly for the Curiæ, and the Forum, properly so called, or place of assembly for the Comitia Tributa. Bunsen, in his work on the Roman Forum, quoted by Arnold ('History of Rome,' vol. ii., p. 165), judging from the views of the rostra given on coins, supposes that "it was a circular building, raised on arches, with a stand or platform on the top, bordered by a parapet, the access to it being by two flights of steps, one on each side. It fronted towards the comitium, and the rostra were affixed to the front of it, just under the arches. Its form has been, in all the main points, preserved in the ambones, or circular pulpits, of the most ancient churches, which also had two flights of steps leading up to them, one on the east side, by which the preacher ascended, and another on the west side, for his descent. Specimens of these old pulpits are still to be seen at Rome, in the churches of S. Clement and S. Lorenzo fuori le Mure." The orators appear to have walked up and down the rostra in addressing the people, and did not, like modern speakers, remain standing in one spot. Down to the time of Caius Gracchus even the tribunes in speaking used to front the comitium; but he turned his back to it, and spoke with his face towards the forum. (Niebuhr, 'History of Rome,' vol. i., note 990; vol. iii., note 268.)

ROTATION (*Rota*, a wheel). The popular conception of a body in rotation is vague, except only in the case in which the rotation is made about an immoveable axis. This subject has accordingly been usually treated by mathematical methods; and mathematicians content with their results, and with their power of interpreting them, did nothing towards the improvement of the manner of presenting the elementary view of rotation. M. Poinsot first divested the subject of its previous complexity, in a Memoir read to the Academy of Sciences, May 19, 1834.

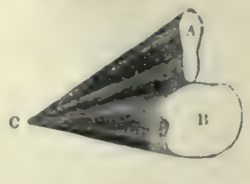
There is this parallel between the conception we form of the simple motion of a point and that of a solid body, namely, that each has a case of peculiar simplicity, by which others are rendered more easy to describe. A point may move in a straight line, or may preserve its direction unaltered; a body may revolve round a fixed axis, or each point may preserve its circle of revolution unaltered. But owing to the comparative simplicity of the motion of a point, it is easy [DIRECTION] to carry with us, when it moves in a curve, the idea of its still having a different direction at every point of the motion, namely, that of the TANGENT of the curve. It is not so easy to see that whenever a body moves about a fixed point, no matter how irregularly, there is always, at every instant of the motion, some one axis which is, for that instant, at rest. This notion of an instantaneous axis of repose, not continuing to be such for any finite time—answering to that of an instantaneous direction in curvilinear motion, which does not continue for any finite time to represent the direction—must be first distinctly formed, before any satisfactory account of the rotation of a body can be given.

Let us suppose a uniform sphere, with a fixed centre, but otherwise free to move in any way. Let a succession of forces act upon it, gradual or not, in such a manner that it will never move round one axis for any finite time during the continuance of their action. At a certain moment, let all the forces cease entirely, leaving the sphere to itself. It is easy enough to see that from and after the moment of discontinuance, the sphere will move round an axis which remains unaltered. There must then, at the very moment of discontinuance of the forces, have been an axis which was for that moment at rest, namely, the axis on which the motion is to continue after the forces cease. In this way, knowing that curvilinear motion would become rectilinear the moment that the deflecting forces are removed, we may form an idea of the tangent of a curve, the line of direction for the time being.

One of M. Poinsot's remarkable propositions is the following:—Any motion of a system round a fixed point may be attained by cutting a cone (in the most general sense of the word) out of the body, with the fixed point for a vertex, and fixing in space another cone for it to roll upon, also with the fixed point for a vertex.

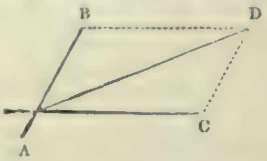
Thus if, in the adjoining diagram, the cone A be made to roll upon the cone B, both being supposed destitute of impenetrability, so that the contact of the curves of A and B can always be made, and if the system out of which A is cut be then restored (also without impenetrability), there will be a complete geometrical representation of one possible motion of the system about C. Moreover, there is no possible motion which might not be represented in the same manner by properly choosing the cones A and B, and the axis of repose for the instant is the line in which the two cones touch.

If we suppose no fixed point in the system, so that motion of translation, as well as of rotation, is possible, M. Poinsot has given another equally distinct notion of the state of the motion during an infinitely small time. The most simple notion which we can form of a combined translation and rotation is the screw-like motion, in which a uniform motion of translation is accompanied by a uniform motion of rotation round a line parallel to the motion of translation. M. Poinsot has shown that every motion of a system must be, at any one instant, either a simple motion of translation, or one of rotation, or the screw-like motion above described. That is to say, at every point of time in the motion of a system there exists a line (whether internal or external to the *material* system matters not, so long as they are immoveably connected) along which the system is at that instant sliding, while all the rest of the motion at that instant is simple rotation about that *slipping axis*.



Let us now suppose a system to receive at the same time two motions, round two different axes of repose: that is to say, given two different motions, required the motion which will result from the two motions impressed on the system at once. There will be at the first instant an instantaneous axis of repose, which it is required to find. First let the two axes pass through the same point A (*Fig.* 1), and choose the angle B A C out of the four angles made by the two axes, in such manner that points of the system lying in the angle B A C would be elevated by the rotation round B A, and depressed by that round C A, or *vice versâ*. On the axes take A B and A C, lines proportional to the angular velocities about those axes, complete the parallelogram A D, and draw the diagonal A D. Then A D is the axis of repose at starting (which however it may not continue to be), and A D represents the angular velocity round that axis at starting, in the same manner as A B and A C represent the impressed angular velocities about A B and A C. [COMPOSITION.]

Fig. 1.



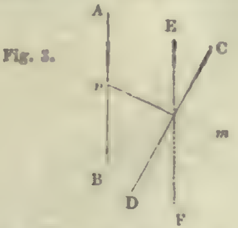
Next let the axes be parallel to one another, say perpendicular to the plane of the paper, passing through A and B (*Fig.* 2). If the rotations be such that A and B would both rise, or both fall, on the paper, each by the rotation about the other, take a point C in B A produced, nearest to the axis about which the angular velocity is greatest (say that of A), and such that C A is to C B as the angular velocity about B to the angular velocity about A. Then the axis of repose at starting is a line passing through C parallel to the former axes, and the angular velocity is the difference of the angular velocities about A and B, and in the direction of the greater. In this case the directions of the rotations about A and B [DIRECTION OF MOTION] are different. There is one remarkable case, namely, when the rotations about A and B are equal. In this case the rule would lead us to a rotation equal to nothing made about a point at an infinite distance—one of those extreme conclusions which require interpretation. The fact is that these two rotations give only a simple motion of translation = A B × Angular Velocity per second, and such as to make the system move upwards or downwards on the paper according as the separate rotations would make the points A and B move upwards or downwards. This particular case will be more intelligible when looked at with the help of the THEORY OF COUPLES.

Fig. 2.

But if the rotations be in the same direction, so that A will be lowered and B raised, or *vice versâ*, each by the rotation about the other:—Take a point D, dividing A B so that A D is to D B as the angular velocity about B is to that about A. Then will the axis of repose at starting be a parallel drawn through D to the axes passing through A and B, and the angular velocity will be the sum of the angular velocities about A and B, its direction being that which lowers A on the paper and raises B, or *vice versâ*, according as is done by the given angular velocities.

Lastly, let the axes be neither parallel nor intersecting (*Fig.* 3), as A B and C D:—Through the point *m*, in which C D meets the common perpendicular, *m n*, draw E F parallel to A B, and at the instant at which the rotations round A B and C D commence, impress two equal and contrary rotations about E F, each equal to that about A B. These produce no effect, so that the composition of the four rotations gives the same result as that of the two. Now, as above stated, the rotation round A B, and its equal and contrary round E F, produce nothing but a motion of translation, while the remaining rotation about E F, compounded by the first rule with that about C D, gives what would be an axis of repose, if it were not for that translation. The whole result then is, that the system begins to move about an axis, which axis begins to undergo a translation in space.

Fig. 3.



For higher theoretical investigations in this subject, the reader is referred to the writings of M. Poinsot. The best practical view will be derived from experiments with the GYROSCOPE. See also an article on the Gyroscope by Mr. John Bridge in the 'Philosophical Magazine' for November, 1857.

ROTATION OF CROPS. It has been observed in a former article [ARABLE LAND] that a repetition of the same crops in succession has a peculiar effect on the soil, so that if grain of the same nature be sown year after year in the same ground, it will not produce the same return of the seed, even when abundantly manured. The reason of this is not satisfactorily explained, but the experiments which have been made by men of science lead us to conclude that the real cause will be gradually discovered; and considerable advances have been made towards a rational solution of the question. It has been observed that it is the formation of the seed which principally causes the deterioration of the soil; for if the crop be fed off in a green state, or mown before the seed is formed, the same may be safely repeated, and no diminution of the plants is apparent. Thus grasses in a meadow which are mown before the blossom is faded or the seed formed, will spring up again vigorously; but if the seed be allowed to ripen, the roots die away, and the best grasses gradually disappear. It is thus that when a meadow is mown year after year for hay, and the earliest grasses are allowed to ripen their seed, the crop will be later and later, and all the earliest grasses will disappear. Irrigation prevents this, and seems to restore to the land whatever the grasses require for their continuance. Feeding off the meadows does the same; and this leads to the conclusion that water restores the power of production; and that the grasses not being permitted to run to seed, the deteriorating effect is not produced.

If it had been a mere exhaustion of the nutritious particles in the soil which caused the deterioration of the subsequent crops, some kind of manure might restore the fertility; but this is not the case. However judiciously the land may be manured, it is not practicable to raise a crop of wheat or clover, or of many other plants, on a soil which has shown that, as the farmers say, it is *tired* of that crop; but clover grows well after wheat, and wheat after clover, so that the same effect is not produced in the soil by these two crops. A plant which has fibrous roots, and throws up a seed-stem with few leaves, thrives best after one which has a fleshy root and many succulent leaves on a branching stem. Thus, wheat and oats thrive after beans or clover; barley and oats after turnips, carrots, or potatoes. Independently of the manure which may be put into the ground, the crops will be better where the proper succession is attended to, than where plants of a similar kind are made to follow each other.

In all countries where peculiar attention has been paid to agriculture, the most advantageous succession of crops is generally known; and if any deviation takes place, it is as an exception to the rule, and is not looked upon as a model for imitation, but rather as an experiment of a doubtful result. Certain general principles are commonly admitted as fully established; the chief of these is, that a plant with a naked stem and farinaceous seed should follow one with a branching stem and a fleshy root, which has been taken from the ground by mowing or feeding before the seed was ripe; or if all these conditions cannot be obtained, that some of them at least should be complied with. Wheat sown after clover, which is allowed to be the best succession on light soils, fulfils all the conditions: when it is sown after beans, the condition of the preceding crop not ripening its seed is given up; and consequently this succession is inferior to the other, but it is admirably effective nevertheless on all heavy soils. Potatoes, at first sight, appear to fulfil all the necessary conditions; but although they do not often ripen the seed above ground, in the formation of the tubers the soil is notoriously deteriorated.

In order to find the crops which may advantageously succeed each other in rotation, many circumstances must be taken into consideration. First of all the quality of the soil, and its fitness for particular crops; next the wants of the farmer and his family, and the maintenance of the stock required to produce a sufficient supply of manure. It is unreasonable to expect poor light land to produce wheat and beans, although by high cultivation these crops may be forced. Rye, oats, and roots may give the farmer a better profit, by being raised at a less expense than more valuable crops, which must be forced with manure, and at best are precarious in soils not adapted to their growth. In moderate loams wheat may recur every fourth or fifth year, whereas in very rich compact loams it may recur every third, and even every alternate year. Clover and many artificial grasses do not succeed well if they recur oftener than every sixth year, or with even a longer interval. Rape, flax, and potatoes require a still more distant recurrence on the same ground. All these considerations lead the farmer to the selection of the most advantageous rotation for the soil of his farm; and where the land in a considerable district is nearly of an uniform quality experience soon establishes a course which no one finds it prudent to deviate from. It happens frequently however that a great variety of soils, very different in their nature and fertility, are intermixed; and then, unless the farmer can apply the true principles of rotations, he may greatly err by following the course, which may be very judicious for the prevailing soil of the district, but not at all suited to some of his fields. Hence a knowledge of the crops suited to any particular soil, and the order in which these crops should succeed each other, is indispensable to the advantageous cultivation of a farm.

That which forms the food of man is always the principal object in the cultivation; and, excepting rice, which only grows in warm climates, there is no food more universally used than that which is made from wheat. Rye, barley, oats, and pulse are only substitutes where wheat cannot be raised in sufficient quantities. Next to grain comes meat, chiefly beef, mutton, and pork, of which the consumption increases with the wealth of a nation and the advance of its agriculture. Wheat and fat cattle are therefore primary objects with every good farmer; and he who can raise most wheat and fatten most oxen or sheep or pigs will realise the greatest profit.

Many circumstances may indicate a deviation from the course which, as a general rule, is most advantageous. The facility of purchasing manure from neighbouring towns may allow of more frequent crops of corn, and of nutritious roots which require much manure, such as potatoes, and which give no return to the land in the shape of dung. But we must lay down rules for those who are to rely on their own resources to recruit the land with manure, so that it may give the greatest produce without diminishing in fertility; and this can only be done by a judicious feeding of livestock.

The simple rotation of wheat and beans alternately would be by far the most profitable in rich clay soil, as both these crops always obtain a good price in the market; but if a whole farm were so cropped, nearly all the manure must be purchased; for, after a few crops, the wheat-straw and bean-halm would not produce half the manure required for the land. Hay and oats must be purchased for the horses required for the tillage, which might not be procured so readily or so cheap as they may be raised on the farm. On very light sands wheat or beans cannot be raised, except by a very expensive mode of cultivation; but rye, oats, peas, buckwheat, and roots for cattle must be substituted. On chalky loams the principal crops are barley and artificial grasses for sheep. In short, no particular rotation can be prescribed without a complete knowledge of the soil, the locality, and every circumstance connected with any particular farm. As the most universal rule, it may be laid down that every alternate crop should be consumed by animals on the farm, and that, as much as possible, the plants which succeed each other should be of different natural botanic families. Experience has generally shown the time that should be allowed to intervene between the recurrence of the same kind of crop, and we have only to form our plans accordingly.

Of the old triennial course (fallow, wheat, barley or oats) it must be observed that the two corn-crops so rapidly deteriorate the soil, that a complete year of fallow is required to purify it, and a good manuring to keep the land in heart, and that all the industry of the farmer cannot keep up the fertility of the land without extraneous help, either from the manure made in towns, or in the farm-yard by cattle bred and kept in commons or pasture-grounds. This system, which prevailed so long, cannot be called a rotation; and no real improvement was introduced into agriculture until the notion of its perfection was exploded, and tenants were permitted to deviate from it. The rotations adopted in the place of this old system necessarily partook at first of its main defects. Green crops were introduced of necessity to supply the loss of the commons and pastures, which, as the population increased, were gradually cultivated as arable land: but the two white crops remained in succession, and even now, such is the force of habit and early impression, that one of the most difficult points to be gained with practical farmers, accustomed to the old rotations, is to make them have patience when their land is in a good state, and to prevent their sowing a white crop, which is immediately profitable, instead of a green crop, which will keep the land in heart and improve it for future crops, but which does not figure in the account of sales. Yet it can be clearly shown, that in most cases the second corn crop is dearly purchased by the expense required to restore the land to the state in which it was when the seed was sown a second time: manure alone will not do this; fallowing and repeated ploughing can alone effect it: and whether you plough several times before a crop, or are forced to do so after it, there is no difference in the expense of labour, although there may be much in the value of the subsequent crops.

The Norfolk course (turnips, barley, clover, wheat), which is so well known and deservedly in repute for light sands, has only one defect, which is the too frequent recurrence of clover. Rye grass, the usual substitute in sandy soils, unless it be fed off young, is far inferior to clover as a preparation for wheat, and this accords with theory; for wheat and rye grass are both of the natural family of the *gramineæ*. Tares or vetches are a good substitute in heavy soils, as well as beans, both of which are *leguminosæ*, but not well suited to light sandy soils. Peas are sometimes introduced; but they are apt to encourage weeds, unless the crop be very heavy, and then they exhaust the soil, and leave little vegetable matter behind them in their roots.

In many countries there are other vegetable products, which are required for the food of the inhabitants, or supply the raw materials of manufactures: these must be introduced into the rotations, according to their effect on the soil and the cultivation they require. Indian corn, or maize, and French beans, for their seed, are cultivated in more southern climates as field crops. Potatoes are now an essential product in some districts, and one which, after maize, produces the greatest quantity of food for man from a given portion of land. But potatoes require much manure, and cannot profitably be cultivated to a very great extent as a farm produce, nor repeated on the same land, for any length of time, oftener than once in eight or ten years; they should however always enter into the rotation in that portion of the land which is to be much worked, cleaned, and manured after a crop of corn.

We have ourselves for many years adopted a rotation without being tied down to any positive rule, which has been suggested by circumstances, and in some measure regulated by our conviction of the truth of the theory we have attempted to elucidate. In a clayey loam on an impervious subsoil, but mostly completely drained, we have had turnips and swedes on high ridges, tares, mangel-wurzel, potatoes, and a portion of rye to cut up green; succeeded by barley and oats sown with clover, rye-grass, and other biennial grass seeds. These were mown for hay the first year, and sometimes the second also, but generally depastured one year at least; then followed beans, and after these wheat. The green crops were put in after repeated and deep tillage, and with an ample allowance of manure. The whole of the layer was top-dressed with peat or coal ashes in the first year, and what manure could be got or spared was put on the second year before winter, when it was ploughed up. All the corn crops were put in upon one shallow ploughing. We have had no reason ro repent of pursuing this course: but we allow that one year only in clover would probably be more profitable. The land is not sufficiently fertile by nature to bear wheat after the first year of clover, instead of feeding or making it into hay. This would bring it to some of the rotations adopted in rich alluvial soils. It is a rule which should never be transgressed, that after every crop reaped there should be a remnant of manure sufficient to ensure a good crop the next year; and that this should always be in the land, and considered as stock in trade or capital invested at good interest. By means of judicious rotations and thus a much greater quantity of produce may be raised at a certain expense of labour and capital, than by any desultory and experimental mode of cropping. The farmer should find it his own interest to cultivate his land according to the most approved principles, and the landlord should impose only such restriction as will prevent the tenant from injuring himself by diminishing the produce of his farm.

It is in the relation of crops to manure—to the need of it for them, and the supply of it through them, that the practical man sees the advantage of rotations. There is a need of rotations arising out of our relations to our labourers who want constant employment—to our live stock, which need constant food—to the soil, which will not continue to produce the same plant perpetually—to the plants we cultivate, which grow more luxuriantly in rotation than in constant succession. And the explanation of this last fact has been founded on the ideas that (1) crops poison the land for themselves; (2) that they exhaust the land for themselves; (3) that they improve the ground for their successors. Turnips for instance consumed on the land bring on it more nitrogenous matter than was given them in their manure; and so the land is enriched by this practice and rendered fit for grain, which on the other hand uses more nitrogenous matter than it can in general naturally obtain.

The following are our common rotations—

1, is the Norfolk rotation—2, the North of England modification of it—3, Mr. Thomas's, of Lidlington, modification of it—4, a common modification of it in Norfolk—5, the East Lothian 6-field rotation—6, a common modification of it—7, the Whitfield 8-field course—8, Hewitt Davis's light land rotation—9, the rotation of the Cotteswold district, Gloucestershire—10, common in the fens of Lincolnshire—11, in clay-lands, East Lothian—12, carse-lands of Scotland—13, clay-lands of Essex. These rotations vary greatly in their manure producing power. By some one cwt. of meat may be made per acre—by others not a quarter of a cwt.—By some therefore there is food per acre for an ox, making 20 tons of dung for every 4 acres, and on others hardly one for every 16 acres.

ROTATORY OR CIRCULAR POLARIZATION. [POLARIZATION.]

ROTE, a musical instrument of former times, mentioned by the early French writers of romance, and by Chaucer, as well as others among our early poets: it seems to have been similar to what the French call a *vielle*, and the English a hurdy-gurdy.

ROTTENSTONE. [EMERY; *Tripoli Powder*.]

ROTUNDA, a term applied to buildings which are circular in their plan both externally and internally, or else to halls and other apartments of that shape, included within and forming merely a portion of the edifice containing them. The technical application of the term is however restricted to circular buildings whose height does not much exceed their diameter, for we should not describe a lofty cylindrical edifice, such as a round tower, by the term rotunda; while on the contrary it is frequently employed to designate polygonal buildings which approach in their general form to the circle.

In ecclesiastical architecture circular and polygonal structures were by no means uncommon among the early Christians, especially for baptisteries and sepulchral chapels. The tomb of Theodoric, or what is now called Santa Maria Rotunda, at Ravenna, is a singular example, having a flattish or segmental dome (about 34 feet in diameter) cut out of a single block of stone. Of San Stefano Rotundo and Santa Costanza mention has been made under ROMAN ARCHITECTURE, and to them may be here added the Rotunda or Church of Santa Maria Maggiore at Nocera, a work of about the same period. While it greatly resembles Santa Costanza in plan, having coupled columns placed on the radiating lines from the centre, and with arches springing from them, it differs altogether in section from both those examples, there being no cylindrical wall or tambour above the colonnade, but the dome springs immediately from the columns, and the arches groining into it. Consequently the proportions are much lower, the diameter of the space enclosed by the columns being 39 feet, and the height to the top of the dome 42,—proportions differing very little from those of the Pantheon. The extreme internal diameter is 78 feet. The earlier edifices of this class are, for the most part, of moderate dimensions, but others were afterwards erected on a larger scale, and among them is the celebrated baptistery at Pisa [BAPTISTERY], which is externally about 120 feet in diameter, and 100 in height, exclusive of the dome. Circular churches, or baptisteries, are also of frequent occurrence in Germany and France; and in England are three or four round churches of semi-Norman (12th century) character which are supposed to have been designed in imitation of the Church of the Holy Sepulchre at Jerusalem: such are the round churches at Cambridge and Northampton, and the Temple Church, London.

The rotunda became afterwards in a manner incorporated with or added to the cruciform plan, being raised aloft and placed over that part of it where the transepts intersect the body of the edifice. Nearly all modern cupolas may be described as rotundas elevated above the rest of the building and viewed by looking up into them from below. Thus supposing there was a floor at the level of the whispering gallery at St. Paul's, the dome and space beneath it would form a perfect and well proportioned rotunda, whose height and diameter would very nearly be the same.

In itself alone the rotunda form does not accommodate itself to the purposes of a church: it does not afford space for the processions and occasional ceremonies required by the Roman Catholic worship; nor is it better fitted for the Protestant service from its requiring an amphitheatrical arrangement of seats in concentric curves. Rotundas are accordingly rare even in Roman Catholic churches, yet although such structures are necessarily limited by their form to a moderate size, they derive from it also a grandeur which would not be produced by the same scale according to any other plan. Neither grandeur nor beauty however results as matter of course from the plan alone, because whatever charm that possesses may be nullified by other circumstances. There is, for instance, nothing of the one and not very much more of the other in the rotunda interior of St. Peter-le-Poor's, London, one of the few instances we are acquainted with of such plan being adopted for a Protestant Church. The arrangement of the pews and seats in parallel rows, strikes as a disagreeable contradiction to the shape of the building; and in this case the vaulted dome, which is almost essential to such plan, is wanting, a cove and lantern with windows being substituted for it. Some few dissenting chapels have been built of a circular form, but they are equally unsatisfactory, whether regarded as architectural objects, or for congregational purposes.

Instead of attempting to describe these and other examples of rotundas, we shall put our notices relative to them into a condensed form, and for convenience sake shall include those already mentioned, as their relative sizes can thereby be more readily compared.

Pantheon, Rome. External diameter 188 feet, internal 142, internal height 142. [ROMAN ARCHITECTURE.]

Temple of Minerva Medica. External diameter 110 feet. Interior a decagon 78 feet in diameter and 105 high.

Santa Costanza, Rome. Extreme internal diameter 140 feet; diameter of rotunda within the peristyle and beneath dome 70; height of dome 130.

Nocera, Santa Maria. Extreme internal diameter 78 feet, diameter of dome and peristyle 39, height 42.

Rotunda, Forum Caracalla. Exterior diameter about 100 feet. Corinthian portico hexastyle, triprostyle. Interior diameter 80 feet, height of order 48, entire height 90.

Rotunda at S. Pietro in Montorio, Rome. (Bramante.) Exterior enclosed by a Doric peristyle of 16 columns. Internal diameter 22 feet, height 48. This edifice is generally admired as a classical piece of architecture, but it has many striking defects, and the balustrade (without pedestals) over the peristyle is intolerable.

Madonna di Campagna, Verona. (Sanmicheli.) Exterior 74 feet in diameter, nearly surrounded by a low Doric peristyle of 28 columns, making the entire diameter below 118 feet. Interior an octagon 64 feet in diameter and 101 high.

Capella Pelligrini, Verona. (Sanmicheli.) Elegant in plan, but enormously disproportioned in section. External diameter 40 feet, internal 30. Two orders within. Height to spring of dome 46 feet, entire height 64.

La Maddelina, Venice. (Temanza.) Internal diameter 55½ feet, height to spring of dome 36, entire height 63, or 7½ more than diameter. Arrangement hexagonal, that is, six arched compartments.

Halle des Blés, Paris. (De Mezières.) External diameter 228 feet, interior diameter of the rotunda beneath the dome 127, height to spring of dome 42½, to summit 105.

Possagno. (Canova.) External diameter 116 feet; width of portico 90, projection of portico 55, height of stylobate 10½, internal diameter 90, height 90.

Madre di Iddio, Turin. (Buonsignore.) A rotunda about 130 feet in diameter, with hexastyle, diprostyle, Corinthian portico. Internal diameter 74 feet, height 100; plan four semicircular tribunes, with two Corinthian columns in front of each, bearing the entablature continued over those spaces. Attic with a long panel over each of the four recesses.

Museum of the Vatican, Rotunda. (Simonetti.) Divided into ten recessed compartments: diameter 50 feet.

Radcliffe Library, Oxford. (Gibbs.) Basement a polygon of 16 sides, and 104 feet in diameter. Extreme exterior height 140 feet, interior diameter 88, interior diameter of central space and dome 52, height 90.

Berlin Museum, Central Hall. (Schinkel.) Diameter 67 feet, height of gallery supported by a peristyle of twenty Corinthian columns, around the lower part 21; height to spring of dome 42 feet, entire height 70.

Catholic Church, Darmstadt. (Moller.) Extreme internal diameter 135 feet, peristyle of twenty-eight Corinthian columns supporting dome; diameter of dome and peristyle 102 feet, height to spring of dome 48 feet, to summit 102.

Reading Room, British Museum. (S. Smirke.) Diameter 140 feet; height 106 feet. [BRITISH MUSEUM.]

ROUGE. [METALS. *Iron, peroxide of iron.*]

ROUND (*rotundus*, from *rota*, a wheel) is a term which is indiscriminately applied in common language to everything which has no very sharp corners. A cylinder and a sphere, a wheel and a ball, are equally styled *round*. In geometry, the sphere, cylinder, and cone, are sometimes denominated the "three round bodies," and it would certainly add much to many persons' power of describing shapes if they would learn the meaning of the terms circular, cylindrical, conical, spherical, spheroidal, and annular, for all of which the term *round* is employed without any distinction.

ROUND, a short vocal composition in three or more parts, in the performance of which the first voice begins alone, singing to the end of the first part, then passes on to the second, and afterward to the third, &c., the other voices following successively the same routine, till all are joined together, the round ending at the mark of a pause (𝄐) or at a signal agreed on. This is frequently, but most erroneously, called a *catch*, and sometimes, not less incorrectly, a "Canon in the unison."

ROUND TOWER. Numerous lofty towers, tapering from the base to a conical cap or roof, which crowns the summit, are found in Ireland, and are almost peculiar to that country. That they are of great antiquity appears from their having been considered ancient even in the 12th century, when the British connection with Ireland began. Had they been then in actual use, it is not probable that so accurate a writer as Giraldus Cambrensis, who had been in Ireland, and circumstantially describes them, should not also have mentioned to what purpose they were applied. Dr. Petrie, 'Ecclesiastical Architecture of Ireland,' however, quotes several records between the years 948 and 1170, in which bell towers are referred to, which he seems to be able to identify, in some instances at least, with the existing round-towers.

There are 117 of these towers, or of the sites where they once stood, now known, and there is reason to believe they were formerly more numerous. Some of them are still perfect, and preserve their conical roofs; but only one, the tower of Devenish, possesses the singular ornament of an obtuse crescent rising from the cone, and somewhat resembling what is called the trident of Seeva.

Ardmore tower, near Waterford, had also, within the memory of man, this finishing ornament. In the other towers, the conical caps are either more or less injured, or have altogether vanished. Some few are topped by battlements, but these are all of more modern construction than the towers.

Though most of these round towers were evidently divided into stories, yet Cashel tower is smooth, and even polished on the inside from top to bottom. That at Ardmore was plastered with a very fine and durable cement. The divisions are usually formed by projecting ledges for the flooring joists, which however in some instances were inserted in square holes in the wall, where the ends were still visible not many years ago.

On each floor there is one very small window, and immediately below the conical cap four windows may be traced in the greater number of towers; in one there are five and in a few six windows; and so many as eight appear in one or two of the towers. In a few of these buildings no windows appear in the upper story—only one small loophole. In most of the towers the doors are at a considerable height above the ground, in one even twenty-four feet, in several fourteen, and in others only eight, seven, or six feet, but in none of them are there any traces to assist conjecture as to the mode of reaching those doors, except in those where the door is on the ground, or raised from it by a couple of steps.

The height of these towers varies greatly, one being only thirty-five feet, while the loftiest is one hundred and thirty, but the common range is between eighty and a hundred feet. Some stand on circular bases, which form one or two deep steps round the tower. Thus Donoughmore has a two-step base, each step or plinth being composed of very large blocks of stone. The basement of Kell's tower is square, and the stones are of great size. Killree and Aghaviller, both in the county of Kilkenny, have circular plinths fourteen inches deep, projecting six inches and resting upon a square base formed of great blocks of stone. The tower of Clondalkin, about five miles from Dublin, stands on massive stone-work; and St. Columb's tower, at Londonderry, rises from a vaulted crypt. So also does that at Oughterard, in the county of Kilkenny.

In external character all the towers may be said to agree, since there is only one which does not taper, and in that case the tower is cylindrical throughout its entire height. It is nicely faced, inside and out, with coggle-stones, and filled up with rubble. Though all bear to each other the strongest family likeness, there are many striking differences in the mason-work and in the minor details. The stones in some are truly chiselled, and closely and beautifully laid in fine cement. Some are only coarsely hammered, others merely faced, and of various shapes and sizes, but still well fitted to each other. Some towers are built of round coggle-stones. In all the mortar is as hard as the imbedded stones.

The above and various other little diversities prove that these remarkable structures were erected by various workmen and at very different times, and, as Giraldus Cambrensis says, "according to the manner of the country." Some excellent Irish archæologists imagine that they range in date from the 5th or 6th to the 10th or 12th century.

Their situation on hill or dale is equally variable, nor does any one circumstance respecting their situations seem to be common to all, except their immediate vicinity to a small and very ancient church, though in some instances this ancient building has been replaced by a more modern fabric.

It is a well known fact that the early missionaries usually chose the sites of Pagan places of worship for their churches, and the undoubted relics of Pagan places of worship still remain in close association with these towers, and even in the same churchyard; the pillar stone of witness, the tapering sun-stone, the crombac, the fire-house, and the holy spring of sacred water necessary in the mystic rites, all these, according to some Irish archæologists, are found along with the tower, and the little ancient church, within the same narrow boundary.

The speculations of antiquaries as to the objects of rearing these, mysterious towers have indeed been manifold—penitentiaries, the abode of anchorites, beacon-towers, alarm-posts, places of safety for goods, sepulchral stelæ, bell-towers, trumpet-towers, from whence, by means of the great brazen trumpet, the people were invited to worship, fire-towers, where the sacred fires of Bel or Baal, who was undoubtedly worshipped in Ireland and Scotland, were kept alive, the tower itself being an emblem of the sun-beam or ray of heavenly fire, or finally that they were Buddhic in their origin, and sepulchral in their immediate application, they having been erected over the bones or relics of saints. It now seems to be the opinion of the best authorities that they are the work of Christian architects, and were built for ecclesiastical purposes. They appear to have always stood in proximity to a church or monastery, and in fact to have been employed both for bell-towers and as keeps, or strongholds, into which the ecclesiastics might retreat with the church plate and records, in case of an attack. Their origin, or the type from which they were in the first instance imitated, is however still matter of conjecture.

Before closing this article, it should be mentioned that though these towers are almost peculiar to Ireland, there are two in Scotland, but in that district which, in the very early ages, was in close and constant connection with Ireland.

In other parts of the world, as Andalusia, the Caucasus, Persia, and part of India, towers of all sizes and shapes, and in various situations, have been discovered. As in all these there are some points of resemblance, they may all perhaps prove to be successive links of that long chain of evidence by which these remarkable buildings may even yet be traced downwards from their origin to the pagan rites of the Scoti or Irish.

ROUNDHEADS, a name given to the republicans in England, at the end of the reign of Charles I. and during the Commonwealth. The name seems to have been first applied to the Puritans because they wore their hair cut close, but to have been afterwards extended to the whole republican party. The Cavaliers, or royal party, wore their hair in long ringlets. [CAVALIER.]

ROUT. [RIOT.]

ROYAL ACADEMY OF ARTS IN LONDON. At the accession of George III., painting, sculpture, and architecture, notwithstanding there were eminent artists in all these branches, were in a lower state in Great Britain than in most parts of Europe. Foreign critics did not hesitate to assert, that the ungenial climate or the physical defects of the English presented insuperable obstacles to the attainment of excellence in the arts. Whether these opinions induced the young king to turn his attention to the subject, and endeavour to remove this national stigma, cannot now be known, but it is certain that he soon began to show a strong disposition to encourage the arts.

This avowed disposition of the king encouraged the artists of the metropolis to endeavour to establish an academy of art somewhat similar to that which had long been in successful operation in France. A private academy or association of painters had been formed as early as 1711, under the presidency of Sir Godfrey Kneller; but differences arose between the foreign artists (then an important and comparatively numerous body in London) and the English members, when the latter, with Sir James Thornhill at their head, seceded and opened in 1724 a new academy. On the death of Thornhill, ten years later, his son-in-law proposed to the old society to reunite, and the two bodies formed the well-known "Academy in St. Martin's Lane." All these were, however, rather schools for drawing from the living model and the antique, and promoting mutual intercourse among the artists, than academies on the continental model: that is, in which instruction should be given in painting, sculpture, and architecture, and certain marks of distinction be conferred on the most successful professors of those arts. Several projects had, however, been put forward for the foundation of a royal academy: among others one by Sir James Thornhill, prior to the establishment of the private one above mentioned; one by Gwynn, the architect, in 1749; one in 1753 by the members of the St. Martin's Lane Academy, which probably fell to the ground through the opposition of Hogarth; and another, of which the proposals were issued in 1755. The next effort was more successful. An institution which had been formed in 1754, called "A Society for the Encouragement of Arts, Manufactures, and Commerce in Great Britain," was the first which included among its objects the offering of rewards to the fine arts. In 1760, with the assistance of the above-mentioned Society, who liberally allowed the use of their great room for the purpose, the artists were enabled to open the first public exhibition, which though not entirely satisfactory to the promoters, attracted great attention, and was for several seasons successfully followed by a similar display of their talents at a large room of their own in Spring Gardens. The associated artists were in consequence induced to apply to the king for a charter, which they readily obtained, and in 1765 they were constituted a body corporate under the title of "The Incorporated Society of Artists." The way was thus paved for the institution of the Royal Academy; but its immediate cause was a schism which took place in the "Society" soon after their incorporation. It arose from the claim set up by the directors to fill up all vacancies in their own body; this the members refused to allow, and the directors seceded. They were all men of position and influence, and they at once determined to establish a new and more restricted institution on the model of the French Academy, if they could obtain the protection and patronage of the king. W. Chambers, F. Cotes, G. M. Moser, and B. West presented to him a memorial signed by twenty-two artists, the purport of which was to show the probability that with his royal sanction and encouragement, and by means of an annual exhibition of their works, they would soon be able to raise sufficient funds for the support of a gratuitous national school of art. The memorial stated, "The two principal objects which we have in view are the establishing a well-regulated school or academy of design, and an annual exhibition open to all artists of distinguished merit; we apprehending that the profits arising from the last of these institutions will fully answer all the expenses of the first; we even flatter ourselves that they will be more than necessary for that purpose, and that we shall be enabled annually to distribute somewhat in useful charities." The proposal was graciously received. The plan of a constitution was drawn up by Mr. Chambers, and laid before the king, which he approved, and signed on the 10th of December, 1768. Thus was founded "The Royal Academy of Arts in London, for the purpose of cultivating and improving the arts of painting, sculpture, and architecture."

The artists who signed this memorial were: Benjamin West, Francesco Zuccarelli, Nathaniel Dance, Richard Wilson, George Michael Moser, Samuel Wale, J. Baptist Cipriani, Jeremiah Meyer, Angelica Kauffman, Charles Cotton, Francesco Bartolozzi, Francis Cotes, Edward Penny, George Barrett, Paul Sandby, Richard Yeo, Mary Moser, Agostino Carlini, William Chambers, Joseph Wilton, Francis Milner Newton, Francis Hayman. These, with John Baker, Mason Chamberlin, John Gwynn, Thomas Gainsborough, Dominick Serres, Peter Toms, Nathaniel Hone, Joshua Reynolds, John Richards, Thomas Sandby, George Dance, Francis Hayman, William Hoare of Bath, and Johan Zoffani, composed the original thirty-six academicians. The number forty was not completed till 1780—by the addition of Edward Burch, Richard Cosway, Joseph Nollekens, and James Barry. Their first meeting was held on the 14th of December, when the following officers were elected, namely: J. Reynolds, *President*; G. M. Moser, *Keeper*; F. M. Newton, *Secretary*; E. Penny, *Professor of Painting*; T. Sandby, *Professor of Architecture*; J. Wall, *Professor of Perspective*: Dr. William Hunter, *Professor of Anatomy*. The king appointed William Chambers *Treasurer*, and R. Wilson *Librarian*.

The other academies of Europe which have been established for the advancement of the fine arts and the promotion of public taste, are supported entirely at the expense of their respective governments as *national* objects, and are usually under the control of some person of distinction. Such is the Royal Academy of Paris, founded just a century before. The Royal Academy of London is essentially different from these, inasmuch as it originated in the private munificence of the reigning king, and, since the first years of its existence, has been entirely maintained by the proceeds of the annual exhibition.

The king's adoption of the artists was immediately followed by the most liberal and effective support. He caused apartments for the schools to be fitted up in his own palace of Somerset House, supplied the Society with rooms in Pall Mall for their exhibitions, and for several years made up every deficiency in their expenditure from his privy purse; at the same time he allowed them to reserve 100*l.* a-year to form a fund for necessitous members or their widows, and twice that sum to administer occasional relief to artists in distress, whether they were members of the Society or not. When Old Somerset House was purchased by the nation as a site for a number of public offices, the king took care to reserve a portion of the new building for the Academy. In 1766 the plans of a new site were submitted to the approval of the president and council, and the apartments devoted to this purpose were fitted up with a degree of magnificence worthy of a royal palace, the talents of many of the principal members having been employed in their decoration. In July, 1780, the preparations being completed, the Royal Academy obtained possession of their new residence, by an order from the Treasury to the surveyor-general of the works, and their first exhibition in Somerset House took place in the following year. This friendly superintendence of its affairs and anxious desire to promote the welfare and utility of the Society continued till the unfortunate illness of the king; and a like patronage has been vouchsafed by his successors.

In 1834, a proposal having been made by Lord Grey and the existing ministry to transfer the establishment from Somerset House to Trafalgar Square, where an edifice was proposed to be raised which would be also large enough for a national gallery of paintings, the sanction of the king (William IV.) was obtained, and the necessary arrangements were made with the president and council of the Academy. The apartments, which comprise the whole of the east wing of the National Gallery, were put into their possession in 1836; and they are still occupied by the Academy, though formal notice has been more than once given by the government of their intention to resume possession of them, in order to appropriate them to the use of the National Gallery.

The Royal Academy consists of forty academicians, painters, sculptors, and architects. There is a second order of members, styled associates, twenty in number, from whom alone the vacancies that occur among the academicians are supplied. The body of academicians elect, but the approbation and signature of Her Majesty are necessary to make this election valid.

There are also six associate engravers, who are classed—two as "academician engravers," two as "associate engravers of the new class," and two as "associate engravers." Associates are elected by the body of academicians, from a list of exhibitors who declare themselves candidates for this honour.

There are a treasurer, a librarian, a keeper, and a secretary. A bye-law of the Academy requires that they shall be academicians. These offices are filled by Her Majesty's nomination.

There are four professors, academicians, elected by the general assembly, and approved by the queen, who read lectures on painting, sculpture, architecture, and perspective.

There is also a professor of anatomy, elected by the academicians, with the approbation of Her Majesty.

There are three schools: a school for study from casts from celebrated works of antiquity; a school for study from living models; and a painting school. The first is under the care and direction of the keeper; and the other two are under the care of visitors, annually appointed.

The council consists of nine members, including the president, and has the management of all the concerns of the Society. All bye-laws of the Academy must originate in the council, and have the approbation of the general assembly, and the sanction of Her Majesty's signature to give them effect. The president, council, and visitors are annually elected, and confirmed by Her Majesty's signature.

There are also several honorary members of the Royal Academy, namely, a professor of ancient literature, a professor of ancient history, a chaplain of high rank in the church, an antiquary, and a secretary for foreign correspondence; these, who are always persons of eminence in literature, are elected by the general assembly and approved by the queen.

All persons are admissible as students of the Academy. Nothing but indication of talent and a respectable character are required from them. Their names remain unknown till judgment is passed on the specimens which they send in, and when admitted they receive a gratuitous education from the best masters. All painters, sculptors, or architects, whose works show sufficient merit, are allowed to exhibit with the Academy, and, being admitted exhibitors, they are immediately eligible as associates.

The executive government of the Academy passes in rotation to all the academicians, and half the council retires, and is renewed annually.

The schools of drawing, painting, and modelling are open daily from ten to three and from six to eight, under the direction of the keeper and visitors. A practical course of lectures on perspective is given during the spring. The lectures on anatomy are delivered before the Christmas recess; those on painting, sculpture, and architecture are given twice a week, from January to the end of March. The library is open three times a week.

Prizes are annually given to encourage meritorious students, and those who have gained the biennial gold medal have from time to time an opportunity of being sent abroad to study for three years at the expense of the Academy.

The library of the Academy contains all the best works on art, besides a considerable number of modern prints and a valuable collection of engravings of the Italian school from the earliest period, formed by George Cumberland, for which they paid 600*l*. On the death of Sir Thomas Lawrence, the Academy purchased his collection of architectural casts for 250*l*. (although their apartments could not accommodate them): they are at present deposited in the South Kensington Museum.

Considerably over two thousand students have been reared under the tuition and auspices of the Royal Academy, and among them are included by far the greater number of those who have distinguished themselves as painters and sculptors in this country.

The attention which the Royal Academy has uniformly shown to unfortunate artists in general, and the liberal assistance they have bestowed to such out of their funds, should not be omitted. It appeared in evidence before a committee of the House of Commons, in 1836, that the gross sum which they had expended in pensions to distressed members amounted to 11,106*l*., and the donations to artists, not members, and their families, to 19,249*l*.; and since then, with increased funds, the Academy has acted with still greater liberality. With this generosity the Academy has combined a prudent degree of economy in the management of its funds, both for the purpose of providing against casualties and for the gradual improvement of the establishment. Notwithstanding the large sum they have expended in carrying out the objects for which they were associated, the academicians have accumulated a reserve fund sufficient, as they informed the Chancellor of the Exchequer when the question was mooted of the removal of the Academy to Burlington House, to erect a new building more adequate to their requirements than their present apartments, provided the government would furnish the necessary site.

It will appear from what has been stated, that the Royal Academy owes its corporate existence entirely to the crown, and is neither supported nor aided by any public funds. It has also been shown in what manner it became entitled to accommodation in the National Gallery. Though the exertions of the Academy have been directed to a public object—the improvement of the arts—it differs in no respect from any other body incorporated for literary or scientific purposes, such as the Astronomical Society for instance, and others, which support themselves by their own funds.

Accordingly when in the year 1834 the House of Commons had addressed the king, William IV., requesting him to direct the Royal Academy to furnish them with certain returns explanatory of the constitution of the body and its proceedings, the Academy, though protesting against the attempt to withdraw the Royal Academy from its immediate connection with the crown and to bring it under the control of the House of Commons, having first asked the permission of the king, gave the House all the information that was desired. But in 1839, when an order was made to furnish the House with similar returns in continuation, as well as with the particulars of their domestic expenditure, these returns were not made, and a petition was presented to the House, in which the position and claims of the Royal Academy were fully explained. The petition seems to have produced its effect, and the order was rescinded.

Within the last few years it has seemed on more than one occasion probable that the question of the position of the Academy, both as a private institution and with reference to the public benefit, would come under discussion in parliament, but it has been deferred. This question it does not fall within our province to consider, nor to notice the various attacks made on its constitution and administration. It is sufficient here to have stated what these are.

ROYAL SOCIETY (of London), consists of a number of persons associated together for the purpose of promoting mathematical and physical science. At its formation the more particular object of the members was to assist each other in extending their knowledge of natural and experimental philosophy.

Philosophical societies for the cultivation or advancement of particular branches of human knowledge existed, both on the Continent and in this country, before the end of the 16th century. In Italy, the Florentine Academy and the Academia della Crusca had been founded with the view of improving the language and literature of that country. France had its Academy of Painting and Sculpture, and its Royal Academy of Inscriptions; and the Antiquarian Society in England was founded in 1572.

England appears to have led the way to the formation of a body of men who sought by mutual co-operation to advance the *new philosophy*, as it was called; for Dr. Wallis, in an account of his own life, relates that in 1645, which must therefore have been while the civil war was raging in the country, several persons who then resided in London, at the suggestion of a Mr. Haak, a native of Germany, joined themselves into a club, in which, purposely excluding politics and theology, they agreed to communicate to each other the results of their researches in chemistry, medicine, geometry, astronomy, mechanics, magnetism, navigation, and experimental philosophy in general. Among those who first met for this worthy purpose were Drs. Wilkins, Wallis, Goddard, Ent, and Glisson, and Messrs. Haak and Forster (the professor of astronomy at Gresham College); and the place of their meeting was generally at Dr. Goddard's lodgings, but they occasionally assembled in Gresham College or in its neighbourhood. This is supposed to be the club which Mr. Boyle, in a letter (1646), designates the invisible or philosophical society.

Before the year 1651, Drs. Wilkins, Wallis, and Goddard, having obtained appointments at Oxford, went to reside in that city, where, being joined by Drs. Seth Ward, Bathurst, Petty, and Willis (the last an eminent physician), and Mr. Rooke, they constituted themselves a society similar to that which they had left in London. They met at first at Dr. Petty's lodgings, which were in the house of an apothecary, where they had access to such drugs as they wished to examine; and as often as any of the members had occasion to visit the metropolis, they did not fail to attend the meetings of their former associates. When Dr. Petty went to Ireland in 1652, the meetings at Oxford appear to have been for a time suspended; for that gentleman, writing from Dublin to Mr. Boyle, in the beginning of 1658, expresses his gratification that the club was revived; and in the same year the members met either at the apartments of Dr. Wilkins, in Wadham College, or at the lodgings of Mr. Boyle: the Oxford society continued to exist till 1690, when the meetings terminated. It appears, however, that, in the beginning of 1659, all of them, except Mr. Boyle, who continued to reside at Oxford till 1668, came to London, where they rejoined the friends who had remained there, and where the united clubs were almost immediately strengthened by the accession of several new members. At that time the lectures on astronomy and geometry in Gresham College were delivered, the former by Mr. Christopher Wren, on every Wednesday, and the latter by Mr. Rooke (who had been appointed in 1652), on every Thursday; and these gentlemen, together with Viscount Brouncker, Mr. Brereton (afterwards Lord Brereton), Sir Paul Neile, Mr. John Evelyn, Mr. Ball, Dr. Croone, and others, besides the Oxford members, used after the lectures to assemble for philosophical conversation in an adjoining room. This state of things did not, however, continue long, for during the same year, in consequence of the troubles which ensued on the resignation of the Protectorship by Richard Cromwell, the apartments which had been occupied for scientific purposes were converted into quarters for soldiers, and the members of the society were obliged to disperse.

We learn also from Dr. Wallis that, upon the restoration in 1660, the meetings were revived; and on the 28th of November, in that year, the members came to a resolution that they would assemble during term time in Mr. Rooke's chambers at Gresham College, and during the vacation at Mr. Ball's chambers in the Temple. It was further resolved that the members should constitute themselves a society for promoting physico-mathematical learning, similar to the voluntary associations of men for other branches of knowledge in foreign countries. At this time also a series of resolutions relating to the objects proposed by the society was drawn up, of which the following is a brief outline:—It was agreed that records should be made of all the works of nature and art of which any account could be obtained; so that the present age and posterity might be able to mark the errors which have been strengthened by long prescription, to restore truths which have long been neglected, and to extend the uses of those already known; thus making the way easier to those which are yet unknown. It was also resolved to admit men of different religions, professions, and nations, in order that the knowledge of nature might be freed from the prejudices of sects, and from a bias in favour of any particular branch of learning, and that all mankind might as much as possible be engaged in the pursuit of philosophy, which it was proposed to reform, not by laws and ceremonies, but by practice and example. It was further resolved that the society should not be a school where some might teach and others be taught, but rather a sort of laboratory where all persons might operate independently of one another. Lastly, it was resolved that each member should subscribe his name to an agreement that he would constantly attend the society's meetings, if not prevented by illness or some indispensable business; that he should pay 10*s.* on his admission, and that he should subscribe 1*s.* weekly while he continued to belong to the society; but from this obligation he was to be freed if he chose to withdraw. At the same time Dr. Wilkins was chosen chairman, Mr. Ball, treasurer, and Mr. Croone, registrar. It was agreed to meet every Wednesday, from 3 to 6 o'clock in the afternoon.

The revenue thus raised from the members was intended to enable the society to accomplish the various objects for which it was instituted, and particularly to defray the expenses of the philosophical experiments which it was proposed to make. The intention was, that persons should be sent to travel abroad, for the purpose of collecting information, while others should remain in London, and present the results of their researches at the weekly meetings. It was determined that the members should be formed into committees for the consideration of the subjects which were to be illustrated by experiments, and that the performance of the latter should be assigned to persons who, by their particular talents, were best qualified for the duty. Some of the members also were to be appointed to examine all works on the natural history of foreign countries, that out of them they might prepare directions as a guide in making inquiries concerning the phenomena of the atmosphere and the currents of the sea, and in performing experiments on light, magnetism, &c. It was proposed to bring the results of the researches into one common stock, and to consign them in public registers for the benefit of future generations, without regard to any order in the arrangement; it being considered, that if subjects of a like nature were brought together, persons might be tempted too early to form general systems, which might be detrimental to the progress of philosophy. (Dr. Sprat, 'History of the Royal Society.')

Such were the plan and constitution of the infant society, which was destined, in its maturity, to hold so distinguished a place in the annals of science. Its first recorded steps, which took place Dec. 5, 1660, consisted in appointing Mr. Wren, at the next weekly meeting, to perform an experiment on the vibrations of pendulums, and Lord Brouncker to bring in a series of instructions for conducting some experiments (relating to the temperature, moisture, &c., of the air), the performance of which on the Peak of Teneriffe it was intended to procure.

A week afterwards it was resolved that persons desiring to be admitted should be recommended by some member, and that the election should take place by ballot. No one below the rank of a baron was to be admitted without a scrutiny; and the number of members was to be limited to fifty-five, of whom twenty-one were to be a quorum for elections and nine for other matters. It was agreed also that the fellows of the Royal College of Physicians and the professors of mathematics and natural philosophy in both universities should, if they desired, be admitted as supernumeraries on paying the fees and lending their assistance when convenient. The restriction respecting the number of members was however soon afterwards taken off; and, at this time, candidates who were proposed on one evening were often admitted at the next, or at the second following meeting, though the practice respecting the interval between the application and the admission seems to have been very variable. The president or chairman held his post sometimes during the evening only, sometimes he was appointed for a month, and he was occasionally re-elected. Two persons were appointed to superintend the arrangements for performing the proposed experiments, and one of the members acted as a reporter at the meetings. An amanuensis for copying minutes, and an operator under the superintendents, were engaged as servants, and received salaries.

In that age, the constitution and qualities of material bodies being very imperfectly known, suggestions founded on ill-observed phenomena, and the marvellous relations of credulous travellers, were often thought deserving of consideration from the bare possibility that they might lead to the discovery of useful truths; and this circumstance may serve to account for the apparently absurd inquiries and experiments which appear in the notices of the society's first labours. Thus, in 1661, Mr. Boyle was requested to ascertain the name of the place in Brazil where there was said to have been a kind of wood which attracts fishes; he was also desired to inquire into the truth of the circumstance mentioned by Schotter—that a fish suspended by a thread would turn towards the wind. And in the same year, the opinion that a spider could not get out of a space enclosed within a circle formed of powdered unicorn's horn was actually made the subject of an experiment. The philosopher will however forget these early occupations of the society when he meditates on the works of a Newton and a Davy, which are also recorded in the pages of its history.

The society having presented an address to the king (Charles II.) on his restoration, his majesty expressed much satisfaction that the institution had originated in his reign, and promised to support it with his influence. And in 1662, by the concurrence, it is said, of Lord Clarendon, the chancellor, Sir Geoffry Palmer, the attorney-general, and Sir Heneage Finch, the solicitor-general, he granted a charter, by which the members were incorporated into a society consisting of a president, council, and fellows, under the name of the Royal Society. In this they were declared capable of holding lands, tenements, &c. in perpetuity or otherwise, and of suing or defending in any court of law; a coat of arms was given them, and they were allowed to have a common seal for their use. William Viscount Brouncker was appointed president, and twenty-one persons were appointed by name to form a council. It was further regulated that the president should be elected annually on St. Andrew's day, and that ten of the council should, at the same time, be replaced by ten other persons chosen from among the fellows. (Birch, 'History of the Royal Society,' vol. i.; Weld, 'Hist. of Royal Soc.' vol. i.) This charter being found not sufficiently explicit, in the following year another was obtained, in which the president and fellows are designated the president of the council and the fellows of the Royal Society of London for promoting natural knowledge; and in which, after declaring that the society might hold lands, &c., there is added "Statuto *de alienatione in manum mortuam* non obstante." (Birch, *ut sup.*) Between 1661 and 1664, the king made several visits to the society, and on those occasions experiments were exhibited, for the preparation of which committees of the members were appointed. In 1663 his majesty bestowed a mace on the society, and in 1664 he signed himself, in the Charter-book, its founder; at the same time the duke of York (afterwards James II.) signed himself a fellow.

The Royal Society of London may now be said to have been completely formed, and it must be considered as the oldest of its kind in Europe, if we except the Academy of the Lyncei at Rome. The Académie Française, which, in 1635, had been established by Richelieu, had for its object only the improvement of the French language; and though, in 1657, a number of learned men, among whom were Descartes, Gassendi, and Roberval, were accustomed to assemble at the apartments of Père Mersenne in Paris, for the purpose of making philosophical experiments, and of reading the solutions of such mathematical problems as, according to the general practice of that age, had been proposed to them, yet it was not till 1666 that Louis XIV., at the suggestion of M. Colbert, founded what was then called the Royal Academy of Sciences for purposes similar to those which engaged the attention of the Royal Society. To the latter therefore belongs the honour of having preceded the former in time, and probably that of having in some measure led to its formation. It must also be considered as having been the parent of the numerous scientific institutions which have since been formed in the British Isles as well as on the continent.

From the time of the charter being granted, the business of the society assumed more importance, and in 1664 Mr. Hooke was appointed curator, with a salary of 80*l.* per annum. The west gallery of Gresham College was appointed as a repository for the instruments which were under his charge, and for a museum of natural curiosities which had been given by Mr. Colwal, one of the members. Sir John Cutler also settled on Mr. Hooke 50*l.* per annum, in consideration of his delivering a course of lectures on the History of Nature and Art, under the regulation of the society; and the latter, in the same year, formed itself into seven committees for the purpose of considering the different subjects of which it was cognizant. These were mechanics, astronomy and optics, anatomy, chemistry, agriculture, the history of trade, natural phenomena; and there was, besides, a committee to manage the correspondence. The Royal Society early received many tokens of approbation from foreign nations, as well as from the nobility and the learned in this country. It corresponded frequently with the scientific men in France, and it was invited by Prince Leopold, the brother of the grand-duke of Tuscany, to keep up a mutual communication with the philosophers of Florence. The Germans published in their books favourable testimonials of its labours, and foreigners of distinction often attended its weekly meetings.

The first portion, or number, of the 'Philosophical Transactions,' as the work which the society published was designated, appeared on Monday, March 6, 1665. It contained sixteen quarto pages, with an introduction by the secretary of the society, Mr. Oldenburg, who was considered as the editor; and it was intended that one such number should be published on the first Monday of every month. After the fifth number came out (June, 1665), the public meetings of the members were discontinued on account of the plague which then raged; but it appears from a letter written by Mr. Boyle, at Oxford, to Oldenburg, who remained in London, that several of the members were then in the former city, and that they met and made experiments at his lodgings. From these experiments and the communications made by some of the members, there were formed three more numbers of the 'Transactions;' these were published at Oxford; but the ninth and all the succeeding numbers came out in London. The title of the work was changed in 1679 to that of 'Philosophical Collections,' when Dr. Hooke became the editor; but the former title was restored in January, 1683, with No. 143, which was published by Dr. Plot, who was then the secretary.

The council met again in Gresham College, in February, 1666, but the public meetings of the society did not take place till June in that year. In the same year the great fire, which laid nearly all London in ashes, having compelled the authorities of the city to take possession of the rooms hitherto occupied by the society, the latter gratefully accepted the offer of apartments in Arundel House, and it met there for the first time in January, 1667. The munificent owner of the mansion, Mr. Henry Howard of Norfolk (afterwards earl marshal of England), at the same time presented the society with the library which had been purchased by his grandfather, Thomas, earl of Arundel, and which had formerly belonged to Matthew Corvinus, king of Hungary. This valuable library, consisting of several thousand printed volumes and numerous manuscripts, thus became the property of the society, which immediately took measures to put it under the care of its own officers, and it has been subsequently greatly increased by donations and purchases. Being probably anxious to trespass as little as possible on the hospitality of the noble family to whom the mansion belonged, the society proposed (November, 1667) to raise, by subscription among its members, money to build a college for itself; and by May in the following year 1000*l.* were subscribed. Mr. Howard at the same time generously promised to give the ground for the purpose. The same gentleman also offered a design for the building, and both Dr. Christopher Wren and Mr. Hooke gave plans; but it does not appear that the project was carried any further. In October, 1674, at the invitation of the Gresham professors, the society returned to its former apartments in that college, which had now the name of the Royal Exchange. The west gallery was cleared out for the society as a repository, and the long gallery as a library for the reception of the books, which had till then remained at Arundel House.

Soon after this time the prosperity of the society seems to have suffered some diminution. In 1667, when Dr. Sprat's 'History' was published, there were nearly 200 members; in 1673, it appears that the number was only 146, and of these 79 were persons who had long neglected to pay their subscriptions. This great number of defaulters gave much uneasiness to those who wished well to the society; and the latter, besides making pressing applications for the arrears, seriously contemplated an attempt to enforce payment by legal processes. It does not appear that this last measure was ever put in practice, and the council adopted a more effectual means of promoting the welfare of the society in charging themselves with the duty of delivering lectures on philosophical subjects, and in providing a number of good experiments. The first lecture, in pursuance of this plan, appears to have been delivered in 1674, by Sir William Petty, and it was ordered to be printed. The president (Lord Brouncker) also proposed, in 1668, that a silver medal, worth about twenty shillings, should be given to any fellow, not a curator, who should make before the society any particularly meritorious experiment.

Dame Lady Sadleir, the relict of Dr. Croone, one of the earliest members, left by her will, in 1706, a sum of money for the purpose of founding a lecture *for the advancement of natural knowledge*, to be read before the Royal Society; this did not however come into operation till 1738, when the first was delivered by Dr. Stuart. The Bakerian lecture on electro-chemistry was founded in 1774, and the first was delivered in 1775, by Mr. Peter Woulfe.

In the infancy of the society a due attention to the characters of the persons admitted as fellows does not appear to have been always given; and, in consequence, many joined who neither paid the fees nor contributed any information at the meetings, and, at the same time, the number of those who were excused the payments was found to bear too great a proportion to the whole. In order to remedy these evils, in 1682, the president, Sir Christopher Wren, brought in the draught of a statute in which it was provided that any person proposing a candidate for admission should give his name to some member of the council; at the next or at some following meeting of the council, it was to be considered whether the proposed candidate was likely to be useful to the society or not; if the members were satisfied on this head, the candidate was to be formally proposed at the next meeting, and afterwards balloted for as usual. On his election he was to sign the statute book, and on or before being admitted, he was to pay the prescribed fees. In the same year it was agreed that none except foreigners should be exempted from the payments. It is to be presumed that the persons who were excused the payment of the admission fees or the weekly subscriptions were such as, from the pressure of their circumstances, were unable to incur the expense, or such as, from the services which they rendered to the society, might justly claim the exemption: among those who petitioned to be excused on the former ground is to be found the name of Newton, then resident at Cambridge.

It was proposed, in October, 1674, to refuse to strangers the permission, which had been before granted, to be present at the meetings of the society, from an opinion that members might be unwilling to bring forward their communications in the presence of such persons. And at the same time it was proposed that the members should bind themselves not to divulge what passed in their meetings, it being thought prejudicial to the interests of the society that the particulars of the experiments and communications should be made known before they appeared in the printed 'Transactions.' We read that, on one occasion only, a lady was permitted to be present at the meetings of the society; this was in 1667, when the Duchess of Newcastle, having expressed a wish to that effect, it was agreed to invite her grace, and some experiments, which had been prepared for the purpose, were repeated in her presence.

By the death of Dr. Wilkins (then bishop of Chester), one of the earliest members, the society obtained a legacy of 400*l.*, which, in January, 1675, was laid out in the purchase of an annual income of 24*l.* from certain fee farm rents at Lewes, in Sussex; and in January, 1682, the college and lands in Chelsea, which had been granted to the society, were sold to the king for 1300*l.*; this sum was soon afterwards vested in African and East Indian stock, and from that time the society began to possess a permanent revenue. Till the year 1668 no fixed salary was allowed to the secretary; but Mr. Oldenburg, who had long held that post, received 50*l.* occasionally, and in that year it was agreed to allow him 40*l.* per annum. After his death (1677) two secretaries were appointed, with salaries; but in 1685, Mr. Aston and Mr. Robinson declining on a sudden to serve the society, the council resolved, in order to avoid the inconvenience of being so deserted in future, to have two honorary secretaries; it was agreed also to have a secretary with a fixed salary to transact the business, and the qualifications required in the person who should fill the latter post are stated at length in Birch's 'History,' vol. iv. Of the former, Sir John Hoskyns and Dr. Gale were the two first; and in January, 1686, Mr. Edmund Halley was appointed the paid secretary, at 50*l.* per annum.

In 1701, the society, which till this time had continued to hold its meetings in Gresham College, removed to a spacious house which it purchased in Crane Court, Fleet Street. This house afforded room for the meetings, for the library, and for the museum of curiosities; and here the reading of papers and the exhibition of experiments took place, as before, till the year 1782, when the government assigned to the society apartments in Somerset House. On removing to the latter place, it became necessary to dispose of the museum for want of room; but this inconvenience was obviated in 1826, when the rooms formerly used by the commissioners of the lottery were given up to the society. The rooms in Somerset House were resumed by the government in 1857, other and more commodious apartments being granted in their stead in Burlington House, Piccadilly.

In 1703 Sir Isaac Newton was appointed president of the society, and this honourable post was held by the greatest of philosophers till his death, which happened in 1727. The experiments of Newton on telescopes and on light and colours were amongst the first subjects which gave a value to the 'Transactions' of the society; and the latter showed its sense of the honour which it derived from being able to number him among its fellows, by publishing in 1686, the first edition of the 'Principia.' [PRINCIPIA.]

The service rendered to the cause of science from the beginning of the 18th century has earned for the society the respect and gratitude of every man to whom the advancement of the human intellect is an object of high consideration. The society numbers among those who are and who have been its members some of the brightest ornaments of philosophy and human nature; and it may be said that a large proportion of the discoveries by which the face of science has been changed have been made known to the world through the papers published in the volumes of its 'Transactions.'

It has been said above that the 'Philosophical Transactions' were at first published in monthly numbers: these were afterwards collected into volumes, and, from the commencement in 1665 to the year 1800, the work consisted of 90 volumes. From that time a volume has come out annually, and, up to the present year (1861), 150 volumes have been published. It appears that, till the 47th volume was published, the printing of the 'Transactions' was entirely the act of the several secretaries, the society never interesting itself further in that matter than by occasionally recommending the revival of the publication, when from any circumstance it appeared to be suspended. But in 1752 a committee was appointed to consider the papers which were read before the society, and to select such as should be judged most proper to appear in the future 'Transactions,' and this practice has ever since been followed. The society, however, constantly declares that it never, as a body, gives its opinion on any subject, whether of nature or art, which comes before it, the facts and reasonings stated in their papers resting entirely on the credit and judgment of their respective authors.

Honorary recompenses have been liberally bestowed by the society on persons distinguished by their discoveries in pure science or in philosophy. The first occasion on which the society became possessed of the means of so rewarding merit arose from a bequest of Sir Godfrey Copley, one of its members; this gentleman, at his death in 1709, left 100*l.*, the interest of which, or 5*l.*, was to be given annually to the person who, in the course of the preceding year, had written the best paper on any subject relating to experimental philosophy. The donation has since been put in the more liberal form of a gold medal, and it is awarded indifferently either to foreigners or Englishmen, for the sake of encouraging an honourable competition among the philosophers of all countries.

In 1796, Sir Benjamin Thomson (Count Rumford) presented to the society 1000*l.* in the 3 per cent. stock, for the purpose of forming, with the interest for two years (60*l.*), a biennial prize to be given for the most important discovery, or the most useful improvement, made during the two preceding years on heat or on light. The prize is given in the form of a gold and a silver medal, both of which are struck in the same die. During several of the biennial periods no opportunity occurred of awarding the prize, and at these times the interest was added to the principal sum. The interest of this additional sum is always given with the two medals; and the first who received the prize was Count Rumford himself, in 1800, and the second was Professor Leslie (1804). In 1825 his Majesty George IV., for the purpose of further promoting the objects and progress of science, made to the society an annual grant of 100 guineas in order to establish two prize medals, which are to be presented to the persons who during the year shall make the most important discovery in science or art; and in 1826 the medals were awarded to Mr. John Dalton and Mr. James Ivory.

On delivering to a gentleman the medal which had been awarded to him for his discoveries in science, Sir John Pringle, who held the office of president from 1772 to 1778, made it a rule to deliver a speech, in which, after touching on the history of that branch of philosophy to which the discovery or communication referred, he stated the particular points in which the individual had distinguished himself. The first of these speeches was made on presenting to Dr. Priestley the gold medal for his paper entitled 'Observations on the Different Kinds of Air,' which had been read before the society in March, 1772. This liberal practice, by which the value of the testimonial to the receiver is so much enhanced, is still continued; and it is also become customary, at every anniversary meeting, to notice, in an appropriate speech, the principal circumstances in the life of any distinguished member who may have died during the year.

It is perhaps impossible that, in a large body of men engaged in similar pursuits, differences should not arise; and the Royal Society has not been entirely free from the evils attending disagreements among its members. It will be enough to refer to the dispute about the comparative advantages of blunt and pointed conductors for protecting buildings from the effects of lightning, which in 1778 arose to such a height that the president, Sir John Pringle, felt himself compelled to resign [Pringle, John, in Biog. Div.]; and to the accusations at a later period against Sir Joseph Banks of partiality in the disposal of the medals and even in the election of members. In the first instance, the president may have erred in putting himself at the head of a party in the society; but it is probable that most of the grievances subsequently complained of originated mainly in the disappointed expectations of ambitious individuals. If at any time, however, the complaints have not been without foundation, the elevated character of the papers which for many years have been published in the 'Transactions' shows that the interests of science have been generously placed above every private consideration.

According to the present statutes of the society, every candidate for admission must be recommended by a certificate in writing signed by six or more fellows, of whom three at least must certify that the recommendation is from personal knowledge; and the name, qualifications, &c., of the candidate must be entered in a book kept for the purpose. At the first ordinary meeting in March of each year a list of the names of all candidates proposed subsequently to March 1 of the preceding year, is suspended in the meeting-room till the day of election; and a printed list is forwarded to every fellow of the society. From this list the council select by ballot fifteen names to be recommended to the society for election. The election takes place on the first Thursday in June, when the person elected must appear for admission on or before the fourth ordinary meeting of the society after his election; and previously to such appearance he must pay the sum of 10*l.* for admission money; he must also pay 4*l.* per annum as long as he continues a fellow of the society; but the annual payments may be compounded for by paying at once the sum of 60*l.* Fellows are entitled gratis to a copy of the 'Philosophical Transactions,' commencing with that volume which is published next after their admission. Any fellow disobeying the statutes or orders of the society or council, or defaming the society by speaking, writing, or printing, or doing anything detrimental or dishonourable to the society, will be ejected from it.

A prince of the blood, a peer of the United Kingdom, a member of the privy council, any foreign sovereign prince, or the son of such prince, may be proposed at one of the ordinary meetings of the society and voted for on the same day, notice having been given of such proposal at the preceding meeting of the society. Foreign members are exempted from the obligations which ordinary fellows are enjoined to perform; but their number is not to exceed fifty.

The council and officers for the ensuing year are elected on the 30th of November; the latter consist of the president, treasurer, principal secretaries, and foreign secretary. The new council consists of eleven members of the existing council and of ten fellows who are not so. These are nominated previously to the anniversary meeting.

The ordinary meetings of the society are held once a week, from the third Thursday in November till the third Thursday in June, at half-past 8 P.M., in the apartments at Burlington House.

ROYALTY. The French words *roi* and *royal* correspond to the Latin words *rex* and *regalis;* and from *royal* has been formed *royalté* (now *royauté*); whence has been borrowed the English word *royalty.* The corresponding Latin word is *regalitas,* which occurs in the Latin of the middle ages. (Ducange, *in v.*)

Royalty properly denotes the condition or *status* of a person of royal rank, such as a king or queen, or reigning prince or duke, or any of their kindred. [King.] The possession of the royal *status* or condition does not indicate that the possessor of it is invested with any determinate political powers; and therefore *royalty* is not equivalent to *monarchy* or *sovereignty.* The powers possessed by persons of royal dignity have been very different in different times and places; and have varied from the performance of some merely honorary functions to the exercise of the entire sovereignty. The *kings* (ἄνακτες, βασιλῆες) of the Homeric age were properly a governing class of nobles. (See Müller, 'Hist. of Liter. of Greece,' ch. iv, § 1.) Thus Telemachus says that there are many kings in Ithaca, both old and young, besides himself ('Od.', i. 394); and Alcinous says that he rules over the Phæacians, with twelve other kings ('Od.,' viii. 390). As popular institutions were developed in Greece, the office of king became, in several states, merely honorary, and was particularly connected with the performance of certain ancient religious rites. Thus at Athens, the king-archon (ἄρχων βασιλεὺς) was an annual officer, who had the superintendence of religious affairs; his wife was called, during the year of office, βασίλισσα, or *queen.* (Compare Hermann, 'Gr. Ant.,' § 56.) Rome likewise retained, after the expulsion of its kings, a high sacerdotal officer, named the *king of the sacrifices* (rex sacrificulus), who performed the sacred rites which had formerly been performed by the kings. In like manner the Teutonic kings were only the chiefs of the military and sacerdotal aristocracy of the tribe, and did not possess the entire sovereign power ("nec regibus infinita ac libera potestas,") says Tacitus, 'Germ.,' 7. [King.]

In popular discourse *royalty* is made equivalent to *monarchy* or *sovereignty;* and a king is called monarch or sovereign without any reference to the fact whether he possesses the entire sovereign power or only a portion of it.

It may be added, that the attribute of royalty is sometimes transferred metaphorically to certain animals or species of animals, in order to denote pre-eminence. Thus the principal bee in the hive is called the queen-bee; the lion is known (particularly in fables) as the king of animals; and a species of tiger is styled the *royal tiger.* Compare Sovereignty.

Royalty is also used to describe certain rights in property. Thus on the working of mines of gold and silver in the United Kingdom, the sovereign is entitled to a royalty, as is also the Prince of Wales, as Duke of Cornwall, on the working of tin mines. The term is likewise applied to the sum paid for the use of a patent or a copyright.

RUBEFACIENTS are external agents which cause redness of the part to which they are applied. If long continued, they may, according to their nature, produce inflammation and some of its consequences. In such circumstances they are termed Blisters, or Escharotics. It is however a degree of action short of what entitles them to these appellations which is now contemplated. Thus friction with the hand or warm cloths often relieves spasmodic or neuralgic pains; and a hot poultice or warm fomentations lessen inflammation of superficial or even deep-seated parts. Embrocations, when of a stimulating kind, act as rubefacients; and blisters kept in contact with the surface for a short time only, cause redness of the part, and some remote secondary effects of a very beneficial kind. Many cases of fever in the sinking stage may be recovered by a succession of flying blisters, as these temporary applications are termed, placed on different parts of the body, particularly over parts where the skin is thin. Their action may be expedited by previously rubbing the part with proof spirit or oil of turpentine, or by using a portion of linen steeped in the acetum cantharidis instead of the common blister. By diligent employment of such means many valuable lives may be saved. Rubefacients are also very usefully applied to the spine in many nervous, and some cutaneous diseases.

RUBEOLA is the name given by Sauvages, in 1768, to the disease known as measles [Measles]. He was followed by Willan, Bateman, and other writers on exanthematous diseases. Previous to the time of Sauvages the measles was called *morbilli,* a name which is at present adopted by many medical writers. The term rubeola has been recently applied by Dr. Copland and other writers, to a disease which has been called by Hildebrand and other German writers Rötheln. This disease possesses characters in common with measles and scarlet fever, and is supposed to be a hybrid disease originating in the poisons of these two diseases. However much such a theory may be open to criticism, there seems to be no doubt in the minds of many writers that the disease is very frequent, and that it is confounded with its two parent diseases. The following definition of this disease is given by Dr. Aitken, in his 'Science and Practice of Medicine.' "A specific eruptive disease preceded by and accompanied with fever, watery discharges from the eyes and nose, sneezing, and sore throat. The eruption appears on the third or fourth day, and consists of crimson stigmata, rapidly running together into patches of an irregular shape, with obtuse angles, and of sizes varying from a threepenny to a crown piece, according to the severity of the case. The eruption continues from six to ten days, and terminates in desquamation by furfuraceous scales."

The distinction between this disease and scarlet fever and measles has been pointed out by Dr. Paterson of Edinburgh, and by Dr. Heim of Berlin. The premonitory fever is longer than in scarlet fever, and about the same time as measles; scarlet fever appearing on the second day, rubeola and morbilli on the third or fourth. The rash is more easily confounded with scarlatina than morbilli. It seldom however is of a uniform red as in the first, and the spots are larger than in measles. The eruption in scarlatina and measles remains but three days, whilst in rubeola it remains from five to ten days. The sore throat is a marked symptom of rubeola in its mildest forms, whilst this symptom is very slight in mild cases of scarlatina, and altogether absent in measles. Dropsy is a frequent attendant on scarlatina, but very rare in rubeola, whilst affections of the lungs are common in measles but not in rubeola.

Like scarlet fever it is sometimes a rapidly fatal disorder. The treatment of this disease must be similar to that of scarlet fever. In mild cases little needs to be done. [Scarlatina; Measles.]

RUBERYTHRIC ACID. [Madder, Colouring Matters of.]

RUBIACIC ACID. [Madder, Colouring Matters of.]

RUBIACIN. [Madder, Colouring Matters of.]

RUBIADIPIN. A resinous substance contained in madder root.

RUBIAFIN. [Madder, Colouring Matters of.]

RUBIAN. [Madder, Colouring Matters of.]

RUBIANIN. [Madder, Colouring Matters of.]

RUBICHLORIC ACID. [Madder, Colouring Matters of.]

RUBINDINIC ACID. [Indigo.]

RUBINIC ACID. [Tannic Acids.]

RUBIRETIN. [Madder, Colouring Matters of.]

RUBITANNIC ACID. [Tannic Acids.]

RUBLE. [Money.]

RUBRIC (from the Latin *ruber*, red), a name given to the titles of chapters in certain ancient law-books; and more especially to the rules and directions laid down in our Liturgy for regulating the order of the service. These, in both instances, were formerly written or printed, as the case might be, for distinction's sake, in red characters, and have retained the name though now printed in black.

RUDDER. [Ship.]

RUDOLPHINE TABLES. [Kepler, in Biog. Div.]

RUE (*Ruta graveolens*), a plant, native of the south of Europe, intermediate between a herb and a shrub, of a peculiar yellowish-green colour. Every part of it is marked by transparent dots, filled with volatile oil. The leaves and immature fruits are officinal, and owe their virtue to the volatile oil and a bitter extractive. The odour is peculiar, strong, and penetrating; the taste intensely bitter, aromatic, and stimulating. One hundred parts of the fresh herb dry into twenty-two parts. The quantity of oil obtained by distillation with water varies much according to the period of growth when it is collected. Thirty pounds of the fresh herb before flowering scarcely yield one drachm, while twelve pounds with the fruits almost ripe yield nearly one ounce. Rue possesses powerful, stimulant, anti-spasmodic, and tonic properties. The careless handling of the fresh plant sometimes causes rubefaction and vesication, and its improper employment internally has produced serious results. When judiciously used, it is very serviceable in hysteria and other convulsive disorders; but its incautious administration by nurses to infants should be guarded against.

Oil of rue obtained from the fresh herb is green, from the dried herb yellow. It has the peculiar odour of rue, and a bitterish, acrid, cardamum-like taste. Its specific gravity is 0·911. It does not redden litmus-paper. The oil met with in commerce is rarely genuine, being an artificial compound of oil of turpentine with petroleum and oil of rue.

The pollen of the flowers produces inflammation of the skin, and any of it received into the eyes causes violent lachrymation and other painful effects.

Rue is frequently cultivated as an ornamental plant, for which its curiously cut leaves, their glaucous hue, and the profusion of fine dark yellow flowers appearing for several months in succession, adapt it exceedingly well. It may be increased by seeds, slips, or cuttings. The seed should be sown in March, and when the young plants are two or three inches high they should be put out in nursery rows; but propagating by slips or cuttings is best, especially for continuing varieties, of which there are three or four.

RUFIGALLIC ACID. [Gallic Acid.]

RUFIN. [Phlorizin.]

RUFINIORIC ACID. [Tannic Acids.]

RULE OF THREE. [Three, Rule of.]

RULE (in Law) is an order of one of the three superior courts of Common Law. Rules are either general or particular.

General rules are such orders relating to matters of practice as are laid down and promulgated by the court for the general guidance of the suitors; the power of issuing rules for regulating its practice being considered incident to the jurisdiction of the court. By recent acts of Parliament, the judges are authorised to make rules of a more comprehensive nature, relating as well to pleading as to practice. Formerly each court issued its own general rules, without much consideration as to what was the practice in other courts. Of late the object has been to assimilate the practice in all the courts of common law.

Rules not general are such as are confined to the particular case in reference to which they have been granted. Of these, some, which are said to be "of course," are drawn up by the proper officers on the authority of the mere signature of counsel, without any formal application to the court; or in some instances—as upon a judge's fiat or allowance by the master, &c.—without any signature by counsel; others require to be handed in as well as signed by counsel. Rules which are not of course are grantable on the application, or, as it is technically termed, "the motion," either of the party actually interested or of his counsel. Where the grounds of the motion are required to be particularised, the facts necessary to support it must be stated in an affidavit by competent witnesses. After the motion is heard, the court either grants or refuses the rule. A rule, when granted, may, according to the circumstances, be either "to show cause," or it may be "absolute in the first instance." The term "rule to show cause," also called a "rule nisi," means that unless the party against whom it has been obtained shows sufficient cause to the contrary, the rule, which is yet conditional, will become absolute. After a rule nisi has been obtained, it is drawn up in form by the proper officer, and served by the party obtaining it upon the party against whom it has been obtained, and notice is given him to appear in court on a certain day and show cause against it. He may do this either by showing that the facts already disclosed do not justify the granting of the application, or he may contradict those facts by further affidavits. The counsel who obtained the rule is then heard in reply. If the court think proper to grant the application, or if no one appears to oppose it, the rule is said to be made "absolute." If they refuse the application, the rule is said to be "discharged."

Rules may be moved for either in reference to any matter already pending before the court, as for a change of venue in an action already commenced, or for a new trial, &c.; or in respect of matters not pending before the court, as for a criminal information, a mandamus, &c.

A copy of a rule obtained from the proper officer is legal proof of the existence of such a rule.

RULE, RULER. In a mechanical sense these words are both used for a straight piece of wood, brass, or ivory, from which a straight line is drawn on paper by guiding a pen or pencil along the edge. These rules or rulers are convenient for the laying down of scales, on which point see Scale; Sector; Sliding-Rule.

The word rule, in its more common sense, means a set of directions for the attainment of any required object, and various rules will be found in this work, scattered under many heads. The word rule is generally dropped; thus we do not speak of the rule of addition, or the rule of subtraction, but simply of addition or subtraction. In some isolated cases the word rule is most usually retained, as in the rule of three [Three, Rule of] and the rule of false. [False Position.]

A rule differs from an algebraical formula only in the language employed; both the former and the latter indicate processes to the mind. The rule describes its data at length, and requires many more signs than the formula, which however is much more intelligible than the rule, so soon as its symbols are well understood. For example, when it is known that a, b, c are the units in the sides of a right-angled triangle, the formula for determining c is—

$$c = \surd(a^2 + b^2):$$

the rule is—To find the hypothenuse of a right-angled triangle, multiply the number of units in each side by itself, add the products, and extract the square root of the sum: this square root is the number of units in the hypothenuse required. It might perhaps be thought that the preceding rule might have been expressed more briefly, but the practice of abbreviating the language of rules is almost sure to destroy the sort of advantage which, in one point of view, they possess over a formula. A rule should embody a description of the object to be gained, and the process by which it is to be gained; it should also point out the step at which it is gained, and everything necessary to describe the result. It should even specify the case in which the rule is to be used, or that in which it becomes necessary rather than any other; and should be so complete in itself, that any reader of that class to whom the book is addressed might learn all it teaches (that is, everything but the demonstration) by reading only what comes between the word Rule and the full stop at the end of it. Thus, though we have described the preceding rule in words which some persons may think too many, we should say that they are not too many for the student who is somewhat of a mathematician, and too few for the beginner. For the latter we should state as follows:—To find the hypothenuse of a right-angled triangle of which the two sides are given, reduce the two sides to the same denomination if necessary (feet and decimals of a foot, inches and decimals of an inch, &c., as most convenient), multiply the units in each side by itself, add the results, and extract the square root of the sum: this square root is the number of such units in the hypothenuse as were used in the expression of the sides.

If however many rules are to be learned, it would in all probability be found more easy to learn the symbols of alegbra, that is, to learn to read an algebraic expression and to use formulæ, than to recur frequently to rules.

RULER, PARALLEL. A good form of this instrument is explained under MARQUOI'S RULERS, which is particularly applicable to the case in which numerous and related parallels or perpendiculars are to be drawn. The ordinary instruments are of two kinds, which might well be called parallel *rulers* and parallel *rollers*.

The principle of the common parallel ruler is a parallelogram of constant sides and changeable angles: one side being fixed and the angles altered, the other side changes position, it and its parallels always remaining parallel to the first side and its parallels. Two rectangular rulers are connected by two cross-bars of equal lengths, which move on pivots in the rulers in such manner that the four pivots, two in each ruler, shall be the four points of a parallelogram. The line joining two pivots on the same ruler is always made parallel to the length of the ruler. One ruler being held fixed, and a line drawn with the edge of the other ruler in any position, then any motion given to the other ruler by the rotation of the cross-bars gives, on the edge of the moving ruler, a line parallel to the first line. The defects of this construction are, that the four pivots may not make an accurate parallelogram, in which case the instrument is worthless: and the sides of the two rulers, when the instrument is closed, may not be parallel to one another, in which case all the lines must always be taken off the same ruler. Moreover, one ruler remaining fixed, there is but a small command of distance from it; so that, to gain the parallel required, it may happen that the first ruler has to be advanced, the second brought up to it, the first ruler advanced again, and so on. Now, owing to the rotation of the pivots, this gives an oblique motion to the instrument; so that it often happens, by the time that the required parallel is gained, that the point through which it is to be drawn is off the ruler. To meet this disadvantage, and to give the instrument more extent, three rulers are sometimes put together, each connected with the next by cross-bars in such manner that the cross-bars connecting the first and second have an opposite revolution to those connecting the second and third. At its best however this instrument is rather clumsy; but, such as it is, it is safe and easily earnt, when well made.

The simplest kind of roller is the common round ruler, which, with a little practice, will draw parallels for ordinary use very well. It is good practice in the use of instruments to draw parallels in this way; the ruler being held in the middle and gently allowed to take its own rolling motion. If a ring be well drawn round the ruler, it is good practice in drawing perpendiculars to adjust the ruler so that the ring may roll over the line to which perpendiculars are to be drawn. But a roller which is more easily used is sold in all the shops. It consists of an ordinary ruler of rectangular form, both edges of which are bevelled and divided into equal parts: one side into inches and tenths, the other into inches and twelfths; the inch divisions being made to come exactly opposite each other. A roller is let into a space cut out of the middle of the ruler, in such manner as to project a very little way from the under and upper faces of the ruler. When the instrument is put down on the paper, either of the bevelled edges may be brought down on the paper, or both may be clear of it. In this last case the roller (the efficient ends of which are *toothed* cylinders, the middle part being in a frame) rolls easily, and additional stability is given if, while it rolls, one of the bevelled edges be kept slightly on the paper. The ends of the roller are graduated and a fixed index is in the frame, so that by allowing equal numbers of divisions to pass the index at each roll, a good approximation (though not quite with a draughtman's accuracy) may be made to equidistant parallels. Perpendiculars to a given line are drawn by adjusting the ruler so that opposite divisions of the bevelled edges may travel on the given line. With a very little practice this is an instrument of great power and accuracy. Before using it, draw a line with it, roll it away, and then roll it up again to that line, and see if the coincidence is as perfect as before. Various other modes of trial will suggest themselves: indeed no one should use a parallel ruler at all until he has drawn pairs of parallels across each other, and satisfied himself that he can get the opposite sides quite equal.

A rough construction of this kind was (perhaps is) sold under the title of 'Schlesinger's Patent,' in which a round ruler of wood is simply connected with a flat bevelled ruler, so as to carry it when it rolls. This is meant to rule lines for writing, but it may be made to do good service as a parallel ruler for other purposes.

RUM is a spirit distilled from the sugar-cane, that is, from cane-juice; or from the scummings of the juice from the boiling-house; or from treacle, or molasses; or from "dunder," the lees of former distillations. What is called *pine-apple rum* is not distilled from different substances: it is simply flavoured with slices of pine-apple put into the puncheon. As the entire juice of the cane is not necessary for making rum, the distillation is carried on in conjunction with the manufacture of sugar. The best rum is made from the uncrystallised syrup called molasses. [MOLASSES.] The proportion of molasses made in crystallising a cwt. of sugar varies from 50 to 90 gallons, and depends both upon the climate and the season; being lowest in the Leeward Islands, which have a dry climate, and highest in Demerara and Trinidad. It is in the latter that in fine seasons the proportion reaches 90 gallons per cwt. Nearly one gallon of proof rum may be made from one gallon of molasses.

The rum consumed in the United Kingdom is entirely the produce of the West Indies, and to a great extent of the island of Jamaica, which is of a superior quality. For many years the home demand has not taken off the whole supply; and the surplus, which consists chiefly of the Leeward Islands rum, and other kinds of inferior quality, is exported.

British spirits are said to be extensively sold for rum, the flavour being imitated by the rectifier.

The equalisation of the duties on East and West India sugar, by 6 Wm. IV. c. 26, rendered it expedient to give a practical equality to all the products of the sugar-cane, without which the cultivation of sugar plantations in India could not have been so profitably extended, as the molasses would have been comparatively wasted. The rum consumed in the navy is exempt from duty. That which we re-export is chiefly sent to Germany, Prussia, Holland, Italy, and Australia. After various changes in the mode of arranging the duty, it was determined in 1847 that rum should pay the same amount of Customs' duty as British spirits paid of Excise duty. There still remained a few anomalies, arising out of the excise duty being unequal in different parts of the United Kingdom; but this inequality was removed in 1858, and in 1860 the State was put in the receipt of 10*s*. 2*d*. per gallon on all rum, gin, whiskey, and British spirit of every kind, consumed in the United Kingdom; and an additional 3*d*. per gallon on rum not the production of the country whence imported.

The rum imported in four equidistant years will show the recent progress of the trade:—

1844	3,120,010	gallons.
1849	5,306,827	"
1854	8,625,907	"
1859	6,878,587	"

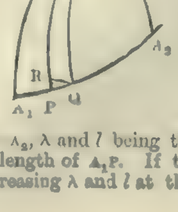
The *computed* real value in 1854 (the first year in which such values were calculated by the Customs), was 1,490,661*l*.; from which the values for the other years named may easily be calculated, supposing the price to have remained unchanged. In looking at the above numbers, it would seem as if rum had been rapidly increasing in consumption in England about the year 1854; but such was not the case. Of the whole quantity imported, only the following (in each year) was retained for *home consumption*:—

1844	2,198,592	gallons.
1849	3,039,862	"
1854	3,226,594	"
1859	3,575,679	"

The large excess beyond these quantities was either re-exported, or consumed on shipboard.

RUMB or RHUMB. Vitalis ('Lex Math.') calls this a Portuguese word, and no doubt it might have been introduced into navigation by the Portuguese, but we suspect it to be the Latin "rhombus;" he says it signified originally the meridian, or the principal meridian of a map; perhaps it came to signify this from such meridian being usually ornamented by a distinctive rhombus, such as is added to the north direction on a compass-card. However this may be, a rumb certainly came to mean any vertical circle, meridian or not, and hence any point of the compass; so that, in modern phraseology, a rumb is one of the thirty-two principal compass directions, and to sail on any rumb is to sail continually on one course. Hence a rumb-line is a line drawn in the sphere, such as would be described by a moving point which always keeps one course; it is therefore the spiral of Mercator's projection, and is that which is also called the loxodromic spiral.

The mathematical properties of the rumb-line may be easily deduced. Let r be the radius of the earth, λ_1 and l_1 the longitude and latitude of



A_1, and λ_2 and l_2 those of A_2, λ and l being those of any intermediate point P: and let s be the length of A_1P. If then we increase s by the infinitely small arc ds, increasing λ and l at the same time by $d\lambda$ and

dl, we have the differential triangle PQR, in which $\mathrm{PQ}=ds$, $\mathrm{PR}=r\,d\lambda$, $\mathrm{RQ}=r\,dl\,.\cos\lambda$, while the angle RPQ, which is the same throughout the curve, may be called ρ. We have then $ds\,.\cos\rho=r\,d\lambda$, or $s\,.\cos\rho=r(\lambda-\lambda_1)$ integrating from A_1 to P. Again, $ds\,.\sin\rho=r\,dl\,.\cos\lambda$, so that the two equations give

$$\frac{d\lambda}{\cos\lambda}=dl\cot\rho,\text{ or }\log\cot\left(\frac{\pi}{4}-\frac{\lambda}{2}\right)=l\cot\rho+\mathrm{C};$$

the logarithm being Naperian, and the angles being arcually measured. If L be the length of the arc of a degree of longitude at the equator, and if we now use degrees, and extend the preceding integration from A^1 to A_2, we have—

$$r\log\frac{\cot(45^\circ-\frac{1}{2}\lambda_2)}{\cot(45^\circ-\frac{1}{2}\lambda_1)}=(l_2-l_1)\,\mathrm{L}\cot\rho;$$

an equation from which ρ can be found for any two places, that is, the angle which the course in sailing from one place to the other makes with the meridian. And instead of $r:\mathrm{L}$ may be put its value 57·29578. The distance from one place to the other on the rumb-line sailed over may be found from $s\cos\rho=r(\lambda_2-\lambda_1)$, which, when λ_2 and λ_1 are measured in degrees, becomes $s\cos\rho=(\lambda_2-\lambda_1)\,\mathrm{L}$, neglecting the small correction for the earth's eccentricity.

The first of these processes can be done by Mercator's chart, the principle of which, mathematically described, is as follows:—Let equal arcs of longitude remain equal throughout the map, but as increments of latitude are to their corresponding increments of longitude as 1 to the cosines of the latitudes, let the differential triangle PQR be similar in the chart to that on the sphere, which gives $a\,d\lambda:\cos\lambda$, for the representation of $d\lambda$ on the chart, provided a represent the length of the degree of longitude on the chart. Hence $a\log\cot(45^\circ-\frac{1}{2}\lambda)$ is the length of λ degrees of latitude measured from the equator; and a table of values of $\log\cot(45^\circ-\frac{1}{2}\lambda)$ is called a table of *meridional parts.*

In such a chart all rumb-lines are projected into straight lines; but equal parts on any such straight line do not represent equal distances on the earth: and the distance sailed must be found by the formula in terms of the extreme latitudes and the angle of the course.

RUMICIN. [CHRYSOPHANIC ACID.]

RUNES, the letters of alphabets in use amongst the ancient Gothic or Teutonic nations of the north of Europe. The word has been derived variously from *ryn*, the Gothic for "to cut;" *rin*, or *ren*, "a furrow," or "channel," from the resemblance of the letters to those objects; *raunen*, the German for "to whisper;" and *ryne* or *rûn*, a "mystery" or "secret art." The two latter derivations are based upon the idea that the Runic characters were taught perfectly only to the priests and ministers of religion; or that they were used as lots when inscribed on small sticks or stones, which, when shaken together and drawn out, served for purposes of augury and divination.

By some writers the invention of Runes has been ascribed to Ulphilas, a Gothic bishop, who flourished about A.D. 350; but more modern investigations have shown that they were far anterior to his time. The circumstance which led to the supposition that Ulphilas had invented Runes, arose from the fact that he introduced Greek characters among the Goths. These he amalgamated with the already existing Runic letters, and formed an alphabet which is now known as the *Mœso-Gothic*, as the Latin characters introduced into England, probably by Augustine, are known as the Anglo-Saxon. Others again have attributed to the Runes a Roman origin; but Tacitus says that the Teutonic tribes possessed letters of the alphabet when the Romans first became acquainted with them, although he calls them "secreta literarum," and thus seems to intimate that the knowledge of letters and their powers was confined to certain classes only of the people. Moreover the pure Runic alphabet consists only of sixteen letters, and these have nothing in common, either in their names or order, with the Greek, the Roman, or the Gothic characters of Ulphilas. The probability is that, according to the opinion of Fr. Schlegel, the alphabet was originally introduced amongst the inhabitants of the coasts of the Baltic by the Phœnician merchants who traded there; that it was only revealed partially to the general body of the people, whilst the priests reserved the full knowledge of it to themselves, in order to establish their claim to superior power and intelligence by the exercise of magic arts and the employment of mystic signs. These signs were frequently cut upon smooth sticks, called rún-stafas, *mysterious staves*, and were used for the purpose of divination and priestcraft.

There is a legend which attributes the invention of Runes to the god Odin or Woden, and which states that he migrated from Asia about the time of the invasion of Darius Hystaspes (B.C. 508); and, having settled in Scandinavia, established temples, a priesthood (to whom he communicated the Runic letters, together with the mythology of the Edda), and became both the legislator and civiliser of the north of Europe. Others again place the migration of Odin at the period of the overthrow of Mithridates by Pompey (B.C. 66), and assert that he fled from the country of the Caucasus, settled in Upsala, and, having distributed Norway, Denmark, and Gothland amongst his sons, was worshipped as a god after his death. Notwithstanding the obscurity of these myths, they seem undoubtedly to point to the fact that the pure Runes were introduced into the North from the East, and that the opinion of Grimm, Schlegel, and those who attribute to them an Oriental origin, is more correct than that of those who suppose them to have been derived from the Greek or Roman alphabets, although there is but little doubt that they became afterwards modified by the introduction of Greek and Roman characters.

The three classes into which Runic letters and inscriptions may be divided are, 1, the Scandinavian or Norse; 2, the German; 3, the Anglo-Saxon; and of these each has its own peculiar alphabet. The origin of the first of them is, as has been already observed, involved in considerable obscurity; the second stands between the ancient Northern, or Scandinavian, and the Anglo-Saxon, and is thus considered by Grimm to have sprung from the former, and to have been the parent of the latter. The Anglo-Saxon Runes were in all probability derived from the Marcomannic or Norman runic alphabets, that is, from the characters used by the Nordalbingii, or Saxons north of the Elbe, who were the progenitors of the Anglo Saxon race. The Marcomannic Runes resemble the Anglo-Saxon, but they do not at all resemble the Norse in form; but all the three nations agreed in attributing the primary invention of Runes to Woden (the Mercury of the Anglo-Saxons), and all of them shared in the belief of the magical properties and powers appertaining to and supposed to be inherent in runic letters and inscriptions.

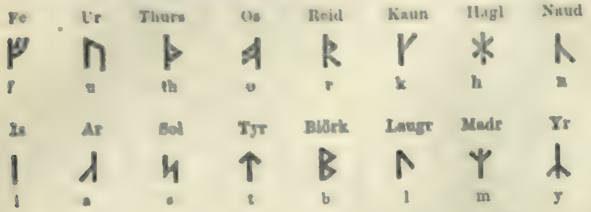
The fact that Runes were generally considered to have been the invention of a pagan deity, that they were used by pagan priests and prophetesses for purposes of augury and divination, and that these priests and prophetesses were regarded by the people with religious veneration and awe, accounts for the proscription of Runes by the primitive Christian priesthood throughout Europe. Hence the Christian missionaries laboured everywhere to introduce Greek or Latin characters, and endeavoured with the utmost zeal to suppress Runes. Notwithstanding this, however, Runic characters were used in England at the very earliest period after the introduction of Christianity, for Christian inscriptions—a circumstance that is incontrovertibly proved by those discovered at Bewcastle in Cumberland, and Hartlepool in Northumberland, and elsewhere. This has been accounted for by the supposition that the earliest converts to Christianity were the pagan priests themselves, and that they, knowing the really worthless character of Runic letters, had not the slightest objection to using them, either by themselves, or in combination with Roman or other letters, either in manuscript or for inscriptions. It is said, however, that by the year 1001 the Runic characters were quite laid aside in Sweden, and were officially condemned in Spain at the council of Toledo in 1115.

The Norse Runic alphabet consisted of sixteen letters, called respectively, *fé*, *ur*, *thurs*, *os*, *reid*, *kaun*, *hagl*, *naud*, *is*, *ar*, *sol*, *tyr*, *biörk*, *laugr*, *madr*, *yr*, and answering in sound to our letters *f*, *u*, *th*, *o*, *r*, *k*, *h*, *n*, *i*, *a*, *s*, *t*, *b*, *l*, *m*, *y*; from which it will be seen that there were no letters corresponding to our *d*, *e*, *g*, *p*, *q*, *v*, *w*, *x*, *z*. Hence the sign of *k* acted also for *g*, *d* for *t*, *b* for *p*, *u* and *y* for *v*. *O* was expressed by *au*; and *e* by *i*, *a*, *ia*, or *ai*. *H* was sometimes used as a substitute for *g* or *gh*, and *u* for *o* or *y*. *Yr* and *or* or *ur* were used as the final *r*. When the insufficiency of the Runic alphabet became apparent, the letters *e*, *g*, *p*, *r* were added, but they received no special names as the old letters did, nor were they expressed by any new signs, but were mere modifications of the old characters *i*, *k*, *b*, *f*. This alteration was effected by means of one or more dots added to the original letter, and the new characters were called *stun nar runir*, or "dotted Runes." And lastly, when the Roman alphabet became general throughout the North, new characters were formed for expressing the sounds of *ae*, *oe*, *ue*, and the letters *c*, *q*, *x*, and *z*; but these cannot be regarded as genuine Runes, and the same remark will apply to the three double Runes, *al*, *mm*, and *tt*.

The Runic alphabet was also used to express numerals, the old letters being employed as far as sixteen; the double letters, *al*, *mm*, and *tt*, for *seventeen*, *eighteen*, and *nineteen*; *twenty*, and over that, being expressed by two letters: for example, *thurs*, *thurs* = 30, *thurs*, *thurs*, *os* = 34. The Runic characters were most commonly written from left to right, and are seldom found running from right to left. Sometimes they are written from the top to the bottom, and then turn up again; sometimes from left to right, and so back to the left again; and numerous examples of them, written in various ways, may be seen engraved in the 'Archæologia,' especially in vol. 28, pp. 338-9.

Runic inscriptions or writings were divided into different classes, from the subjects of which they treated. Thus, Runes imprecating wrath or vengeance upon enemies were called *noxious* or *bitter Runes*; those which were used for deprecating misfortune or disgrace were styled *propitious* Runes; those which invoked victory were known as *victorious* Runes, and those which applied to the healing art were *medicinal* Runes. All these Runes were considered powerful in producing the effect sought by them; and they were consequently employed, not only for the purposes mentioned, but also as antidotes against poison, as love charms, as efficacious in preventing accidents by land or sea, as dispellers of unhappy thoughts and gloomy forebodings, as foretellers of future events, as guards against the evil eye and the jealousies and snares of enemies—in a word, for whatever end might be desired for the person who inscribed them. In order, however, to render them suited to their respective purposes, various ceremonies were observed in writing them, each kind of Rune having its proper material and place for inscription; the shapes of their arrangement being those of serpents, circles, triangles, and similar mystic figures, according to the event which they were intended and expected to bring to pass.

Below is the Norse Runic alphabet. The reader is referred to vol. xxviii., pp. 338, 350, 352, 366, of the 'Archæologia,' for examples of various forms of Runic letters and inscriptions, which are inserted in an able essay of the late John M. Kemble upon Anglo-Saxon Runes.



Runic inscriptions exist upon rings, medals, coins, monumental stones, crosses, and sides of rocks, and a curious one may be seen upon a sword-blade in the Department of Antiquities in the British Museum. They have been discovered in Norway, Sweden, Denmark, in parts of the British Isles, Germany, France, and Spain, in fact wherever the Teutonic race settled itself during the early period of its migrations in the 4th and 5th centuries after Christ.

The most useful information with regard to Runes and Runic inscriptions will be found fully given in Planta's 'Essay on the Runic or Scandinavian Language;' Olaus Wormius, 'Lexicon Runicum;' W. C. Grimm's work, 'Über Deutsche Runen;' Mallet's 'Northern Antiquities;' Hicke's 'Thesaurus Linguæ Septentrionalis;' articles in the 'Archæologia,' the 'Journal of Philosophical Transactions,' and several other philological journals, in which the references required will be found by consulting their respective indexes.

RUPTURE. [HERNIA.]

RURAL DEAN. [DEAN.]

RURAL ECONOMY. The whole subject of agriculture, with all its details, might properly be discussed under this heading: most of it is, however, referred to piecemeal in the various agricultural articles which will be found throughout the Cyclopædia, and it remains here to do little more than enumerate those more general relations of country life, and of the several classes interested in the ownership and cultivation of the land, which have not yet been named.

The common weal depends in great measure on these relations tending to the highest productiveness of the land. We want wealthy landowners in order that any hindrance to the proper cultivation of the land, which stagnant water, defective farm-buildings, and poor cottages present, may be removed. We want enterprising, intelligent, and wealthy farmers, in order that a good machine, which an estate properly equipped undoubtedly is, may be worked to its utmost capabilities; and we want steady, domestic, intelligent, and well-conditioned labourers, because without them it is impossible to carry out the cultivation of the land perfectly.

Under the first head the legislature has granted facilities to the owners of land, and even to the owners of a limited interest in it—as in the case of the life-tenants of settled estates—for borrowing money on land in order to the execution of such works as may tend to its permanent improvement, in the way of draining, roads, fences, farm buildings, cottages, &c.; and there are many companies and associations prepared to carry out such improvements, in return for a rentcharge on the property during a sufficient term of years for their repayment. The legislature has not yet, however, conferred all the facilities required; for landowners are often disabled by the refusal of neighbouring proprietors to concur in schemes for their mutual benefit. This is especially the case where an outfall is needed for the drainage of the property, and can only be obtained through the fields of another. A refusal by a neighbouring proprietor can at present be overruled only by an exceedingly costly and litigious process, and no such difficulties ought to exist in the way of anything which so much concerns the general interest. It is anticipated that a measure will, during the current session of parliament (1861), be introduced by government for granting the facilities required.

Leaving the subject of the relations of landowners to each other, we come to those existing between them and the tenantry on their estates. Under this head the relative merits of tenancy-at-will and of leases for periods of varying duration, of the provisions for ensuring to the tenant the return of all his property spent in cultivation, in the event of his leaving, and the conditions generally under which land is "let" to the cultivator of it, would need to be considered. But on these points we have merely to remark in general, that provision for the security of the tenant's capital when invested on another's land is obviously necessary to the prosperity of agriculture. Such provision is in many districts believed to exist in a long family connection between owners of land and their tenantry, which neither of them willingly break, though instances every now and then occur to show the instability of such arrangements; it is elsewhere made by so-called "tenant-right" agreements, which, co-existent with the right of the owner to give his tenant six months' notice to quit, ensure that the latter should receive on leaving a certain proportion of his expenditure under many different heads, varying in quantity with the period which has elapsed since such expenditure has been incurred. This is the system which prevails in Lincolnshire, and under which large portions of that county have wonderfully increased in fertility. The most efficient way, however, in which the property of the tenant is secured to him, is by a lease of the land for a sufficiently long period to ensure the full fruition of all his plans of improvement and good cultivation. It is in this way that Scottish agriculture is generally so good and Scottish rents are so high.

Lastly, there exists the relation between the labourer and his employer, on which good agriculture very materially depends. The landlord should provide adequate cottage accommodation, and it is the interest of the farmer to attach his labourers to him by personal interest in their welfare, by the payment of wages according to the real merit of the men, and the value of the work they do, rather than by a common rate per diem, including all alike without regard to differences of merit, and thus discouraging individual effort at improvement. The adoption of the allotment system, by which each cottager becomes, at a moderate rent, the tenant of a large garden, either close to his dwelling or in common-field, along with all the others in the village, has the best influence on the character and comforts of the labourer.

RUSH; RUSHES. This material, which is used to some small extent in the arts, is the *Equisetum hyemale*. The stem is very rough, with from fourteen to twenty slender furrows. It is a native of England, Scotland, and Ireland, as well as the continent of Europe; but is almost unknown in the middle and southern English counties, and is only sparingly distributed anywhere. It appears to possess tannin, and to act as an astringent. It is supposed to be injurious to cows, and is said to cause their teeth to drop out; but horses eat it with impunity. This plant, more than any other species, is used for the purposes of polishing. Lightfoot says, that in Northumberland the milk-maids scour their pails with it. Rush is also used for the purpose of polishing wood, bone, ivory, and various metals, particularly brass. It is brought into this country from Holland, where it grows abundantly, and is sold in the shops of London under the name of Dutch Rush.

The well-known *rushes* of country places belong to a different genus of plants from the Dutch rush. They come under the genus *Juncus;* of which one species, the common soft rush, is to be found in most moist pastures, by the sides of streams, and under hedges. In some districts these rushes are used by the poor as a substitute for candles. They are gathered in summer and autumn; the largest and longest being deemed the best. They are kept in water until they are to be peeled; which process consists in divesting the rush of its peel or rind, so as to leave one regular narrow rib from top to bottom, to support the pith. The rushes are then bleached on the dewy grass, and dried in the sun. These rush-piths are finally dipped into any kind of fat or grease, until they acquire a coating analogous to that of a candle. In the bacon districts of Hampshire, hog's fat is employed for this purpose. When White wrote his well-known 'Natural History of Selbourne,' he strongly recommended this feature in domestic economy; but it is possible that the cheapening of candles has lessened the relative advantage of the more primitive system. Rushes are, however, more ordinarily used for plaiting into mats and chair-bottoms, and for constructing small toy baskets. The wicks of rushlights are made of the pith.

RUSH-BEARING, another name in some parts of England for the country wake. It appears that in ancient times the parishioners brought rushes at the Feast of Dedication, wherewith to strew the church, and from that circumstance the festivity itself obtained the name of Rush-bearing. The country wake occurs by this name in the glossary of the Lancashire dialect. In the parish accounts of St. Margaret's, Westminster, is this item, under the year 1544:—"Paid for rushes against the Dedication Day, which is always the first Sunday of October, 1*s.* 5*d.*" Notices of the custom of rush-bearing, as used in various parts of Derbyshire, will be found in Glover's 'History and Gazetteer' of that county, vol. i. (Brand's 'Popular Antiq.,' vol. i.)

RUSHES are well-known plants which appear in all soils, especially those which are fertile, when the water which cannot be evaporated remains in a stagnant state under the surface. They are most common on moist meadows with a retentive subsoil; and as they not only occupy a space which might produce good herbage, but also greatly deteriorate the hay with which they are mixed, every means to destroy them are employed by industrious farmers. Formerly in this, as in most other instances of defect in the soil, only a temporary remedy was generally thought of. The rushes were mown down at particular times of the year, alkaline ashes and salt were spread over them, and in some cases they were destroyed by pouring boiling water on the roots. But all these only killed the individual rushes, without removing the immediate cause of them, or correcting the stagnation of water which invariably reproduced them. The only effectual cure for rushy grounds is a complete system of draining. The truth of this assertion is so generally admitted, that it is unnecessary to dwell upon it. Wherever the land can be effectually under-drained, rushes will generally disappear as by magic. If they are strongly established in the soil, it may take some time before they completely die away, even after drainage, at least in pastures which are not broken up; but if the land is ploughed and has a proper tillage, they will not survive the first year. In rich old meadows, which it would not be prudent to plough up, they may be destroyed by mowing them when they are in bloom, and immediately spreading ashes or salt over the place where they grew. This repeated twice will clear the ground entirely, and the draining will prevent their reappearing.

In heavy grounds which have been laid up in high ridges without thoroughly draining the land, and sown with grass-seeds to remain in pasture two or three years, it is not uncommon to see every interval between the stetches filled with rushes, especially if the land be reduced in fertility by overcropping. This indicates a wet subsoil, and suggests under-draining; but the rushes are often caused by the very roundness of the ridges, which is supposed to keep the land dry, but which accumulates the water in the furrows. If the land had been laid quite flat, it might have been too wet to produce good crops of wheat, but rushes would not have appeared. In very flat meadows rushes are only found where the land lies very low, with an impervious subsoil, or a want of inclination in the surface to carry off the superfluous water. What might at first sight be considered as an anomaly, is yet perfectly true—no rushes are found in the best water-meadows, although they are for a considerable portion of the year entirely soaked in water; but the water is never allowed to stagnate for a moment, and is always kept running on and off.

The great advantage which has been obtained by the system of thoroughly draining compact soils, or those which rest on impervious subsoils, has induced proprietors and farmers of land to employ their capital in this most certain of all improvements, and the consequence will be, that in a few years rushes will only be seen in those low and unprofitable spots from which the water cannot be drawn off by drains, and where they will supply some small resource to the maker of mats and the repairer of rush-bottomed chairs.

RUSSIAN CHURCH. [Greek Church.]

RUST, in the common acceptation of the term, is the red pulverulent substance which is formed on the surface of iron when exposed to air and moisture. It is an oxide of iron, and in point of fact other metallic oxides may be considered as rusts of the peculiar metals which they contain; the term is however limited in application to the red oxide or per- or sesqui-oxide of iron. [Metals. *Iron, peroxide of.*]

RUSTIC or **RUSTICATED WORK**, in architecture, a species of decoration for walls, wherein the joints between the courses, and between the separate stones in each course, are strongly defined by sunk channels or grooves. Although an imitation of what would in itself be offensive, and therefore at first apparently quite at variance with good taste, this mode is only a legitimate, artistical, or æsthetical imitation, suggested by accident or defects. The expression, originally derived from rudeness and coarseness of execution, from large stones irregularly put together, without their edges being smoothed and fitted to each other, is here only partially retained so as to indicate boldness and strength, and also a certain attention to finish and to regularity in the symmetrical arrangement of the courses and stones. There is a studied intention manifested, which prevents our confounding the imitation with what furnished the hint for it. In reality rustication contributes in an eminent degree to richness of surface, and it was accordingly frequently employed by the ancients—by the Romans at least, not only in those works which were characterised by massiveness and by a certain degree of rudeness, such as amphitheatres, bridges, &c., but on the exterior of temples and other edifices, on which the most finished decoration was bestowed. For not only does rusticating the face of the walls occasion contrast, and thereby tend to set off columns or pilasters to greater advantage, but the lines and shadows so produced remove that blankness which might otherwise attend too much uniform plain surface.

Besides being different from plain masonry, rustication admits of great variety, both in regard to design and execution, and of great diversity of character, from severity and heaviness to studied elegance. The most obvious distinction is that arising from the surfaces of the rustics, according as they are either *plain* or *rough*; and if the former, they may be either *smooth*, or *hammer-dressed*, that is, left slightly chipped; else *tooled*, or with the marks of the chisel. Or if intended to be rough, the rustics may be *vermiculated*, *hatched*, or *frosted*. The first of these modes is produced by cutting deep hollows into the surface, the second by making it jagged and rugged, while the third consists in giving a delicate crispness like frost-work to the stone.

As regards *jointing*, there are two modes: one in which the channels between the stones are *grooved*, or form rectangular sinkings; the other in which they are *chamfered*, that is, the edges of the stones are bevelled off in such manner that the section of the joints forms a rectangular triangle. Neither are the above by any means all the varieties, as will be seen by some examples at the end of this article, which cannot be very well explained without cuts. Great variety of character and design may further be produced by an intermixture of the different modes,—for instance, by smooth and rough rustics together, or by different kinds of rusticating for different stories, the bolder and coarser being placed below and the more delicate above.

Italian architecture presents many fine studies and examples of rusticated work. The Florentine style—which, it may be observed, is the direct antithesis of the Palladian—shows what may be accomplished by little more than rustication alone. If it be severe, it is also simple, yet rich and dignified.

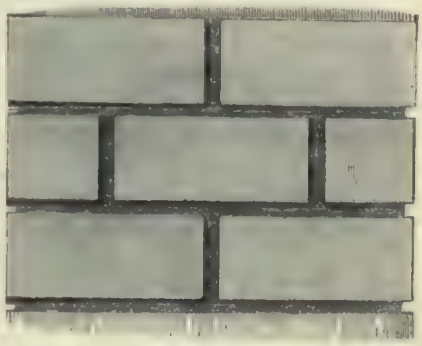
In this country we have very few examples of rusticated work upon a grand scale: for here it is almost entirely confined to basements. It is scarcely ever employed as the general decoration of an entire front, except it be occasionally for prisons, for which it is certainly appropriate, though it does not therefore follow that it is unsuitable where richness and magnificence are more required than severity.

Much of the beauty of rusticated fronts depends upon the form and proportions of the arches or openings, and on the arrangement, &c., of the rustics which form the voussoirs either to arched or straight-headed windows. Occasionally, moulded archivolts are substituted for radiating voussoirs, but the effect is not good, because they cut the horizontal joints of the courses very disagreeably; which, it may be observed, is likewise the case where the voussoirs form an *extrados* either concentric with the arch, or making a more elevated curve, as in most of the Florentine examples. It is far better to make the voussoirs *elbowed*, so as to unite with the horizontal courses, whereby the whole looks firmly bonded together. Sometimes imposts to arches are omitted altogether, or if there be such member, it is usually a mere plat-band, although occasionally it is moulded. In arches the keystone may either be similar or distinguished from the other voussoirs; which last may be done in a variety of ways, although the most usual one is to cut it into the form of a console, or else enrich it with a mask sculptured upon it, of which kind are the keystones to the arches of the Strand front of Somerset House, representing the nine principal rivers of England, personified as old men. *Bossages* is a term more particularly applied to rusticated cinctures on the shafts of columns, which may be either square or cylindrical, but should not greatly exceed the diameter of the shaft itself, more especially in the former case. Columns of this kind ought invariably to be engaged, and the wall behind them of course rusticated also. In such case the cinctures serve as ligatures to bind and incorporate them with the rest, whereas insulated columns with blocks upon their shafts are equally unmeaning and uncouth. The same remark applies to rustic blocks stuck at intervals upon the architraves of doors and windows, as, for instance, those of St. Martin's Church, London, although there is no rusticating in that building. Of columns with bossages or rusticated cinctures, the two arches within the court of Somerset House are a tastefully-designed and well-executed example.

The following are some of the varieties of rusticating above referred to, drawn sufficiently large to show the precise form and section of the joints or grooves:—

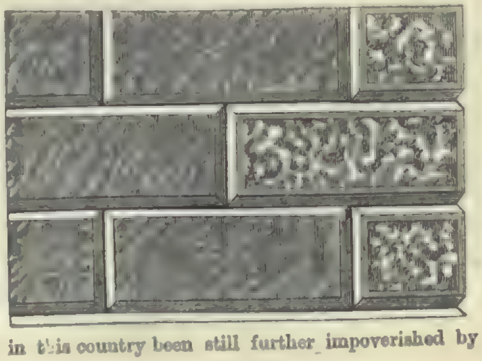
No. 1. Rustics with rectangular joints or channels.

No. 1.



Rustics of this kind have always plain faces. French or horizontal rusticating, without vertical joints, has generally rectangular channels; this sort of rusticating, or pseudo-rusticating with horizontal joints only, has in this country been still further impoverished by making

No. 2.

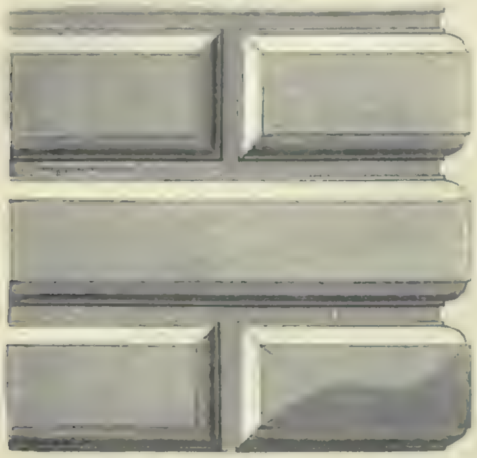


the channels broad and shallow, and the courses so deep that there are only a *few* horizontal streaks along the face of a wall.

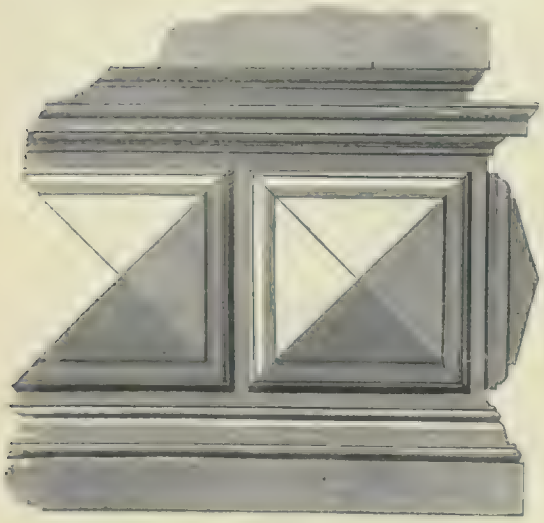
No. 2 is an instance of chamfered joints and vermiculated rustics, bordered, that is, having a plain surface around their faces.

No. 3 shows an example of Florentine rusticating with moulded channels, the effect of which is particularly rich. One of the rustics is *facetted* in the cut, in order to give an example of that mode in rusticated quoins.

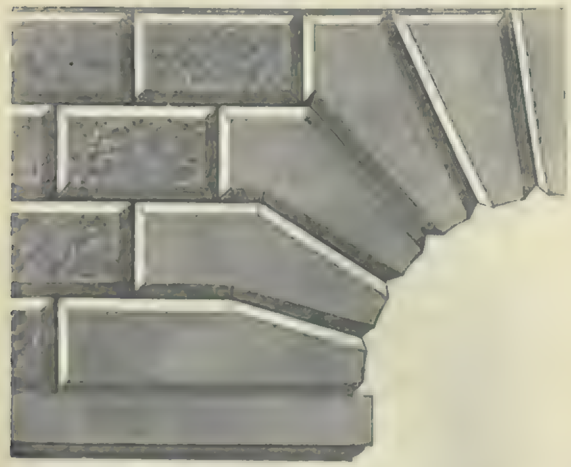
No. 3.



No. 4.



No. 5.

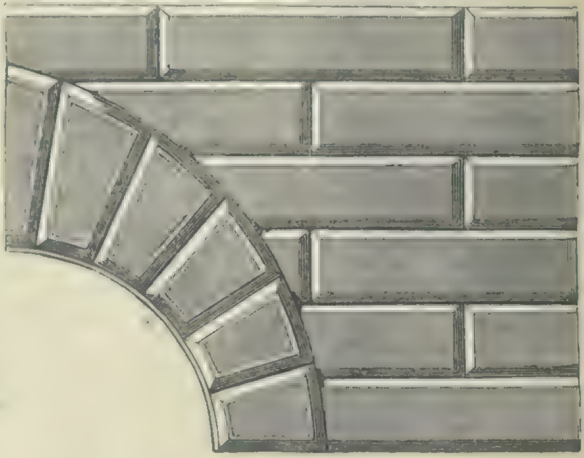


No. 4 is another mode peculiar to the Florentine style, in which the rustics are *facetted*, or cut so as to form four triangular surfaces. It is not used throughout, but only in the lower course, forming a sort of dado to the building. This example is from the same building as the preceding.

No. 5 shows one-half of a rusticated arch having *elbowed* voussoirs running into the horizontal courses.

No. 6 represents half of another arch with voussoirs whose *extrados* form an eccentric curve from that of the arch itself, or else a pointed arch, while the *intrados* form a semicircular one.

No. 6.



RUTAMIDE. [RUTIC GROUP.]

RUTATES. [RUTIC GROUP.]

RUTH, BOOK OF, an acknowledged canonical book of the Old Testament, though Bertholdt and some other German writers have considered it a fiction or parable. The history of Ruth seems to have been inserted in the sacred canon as a necessary link in establishing the pure genealogy of David, and consequently of the Messiah; and perhaps also to furnish a record of the fact that one of the Messiah's ancestors was a Gentile, thus intimating the truth that the Gentiles were to have a part in the highest privileges of the Jews. In the ancient Jewish canon this book forms a part of the Book of Judges, because the events recorded in it happened during the rule of the Judges. Its exact date is however uncertain, but most probably the famine mentioned in verse 1 is that which happened in the time of Gideon, about B.C. 1241. It is generally supposed to have been written by the prophet Samuel. The style is marked by a touching simplicity, and some parts of it are very pathetic. (The *Introductions* of Jahn, Eichhorn, De Wette, and Horne; Umbreit, *Ueber Geist und Zweck des Buches Ruth*, 1834.)

RUTHENIC ACID. [RUTHENIUM.]

RUTHENIUM (Ru). This metal was shown to exist in platinum ores by Clauss in 1845. According to Deville and Debray, who have specially studied the metals associated with platinum, ruthenium may be prepared from the native osmide by mixing it, in fine powder, with three parts of binoxide of barium and one of nitrate of baryta; heating the whole to redness in a crucible for an hour; treating the product with hydrochloric, nitric, and sulphuric acids consecutively; precipitating with chloride of ammonium; igniting the precipitate; and finally fusing the residue with nitrate and hydrate of potash. From the rutheniate of potash thus formed, the *teroxide of ruthenium*, or *ruthenic acid* (RuO_3), may be precipitated by carbonic or nitric acids, and then reduced to the metallic state by heating in a current of hydrogen.

Ruthenium is only fusible with extreme difficulty. It has a blackish-brown surface, and is hard and brittle like iridium. Its specific gravity is 11 to 11·4, and its equivalent 52·11.

Ruthenium and *oxygen* unite in four different proportions. *Protoxide* (RuO); *sesquioxide* (Ru_2O_3), the most stable of these oxides, formed on igniting the metal in a current of air; *binoxide* (RuO_2), obtained by roasting and igniting the bisulphide; and *ruthenic acid* (RuO_3), prepared as already described.

Ruthenium and *sulphur*. The sulphides of this metal are probably as numerous as the oxides, but they are very difficult of preparation.

Ruthenium and *chlorine* form three compounds. The *protochloride* ($RuCl$) results from the ignition of the metal in chlorine gas; it is insoluble in water or acids. The *sesquichloride* (Ru_2Cl_3) is formed on dissolving the sesquioxide in hydrochloric acid; and the *bichloride* ($RuCl_2$), which exists as a rose-coloured double salt with chloride of potassium.

The salts of ruthenium are chiefly those of the sesquioxide. They have a yellow colour, and alkalies re-precipitate from their solutions the sesquioxide as a black powder. A *sulphate*, containing $RuO_2,2SO_3$, has been obtained.

RUTIC ACID. [RUTIC GROUP.]

RUTIC GROUP. A cluster of chemical substances containing the electro-negative radical *rutyl* ($C_{20}H_{19}O_2$).

Hydride of rutyl ($C_{20}H_{19}O_2$, H) *rutic* or *Capric aldehyd.* This body forms the greater part of the volatile oil of the common rue. [RUTA, *graveolens*, in NAT. HIST. DIV.] Its specific gravity is ·837; boiling point from 442° Fahr. to 446° Fahr.; vapour density 5·83. It crystallises in transparent plates at a few degrees below the freezing point of water; gives crystalline combinations with the alkaline bisulphites; is but little acted upon by sulphuric or hydrochloric acids, but is converted into *rutic acid* when placed in contact with nitric acid.

Rutic acid ($C_{20}H_{20}O_4$) or *capric acid.* This acid may be obtained from sources other than just mentioned. It is one of the products of the saponification of butter; it may be formed by the action of nitric acid upon oleic acid; it is contained in small quantity in cocoa-nut oil, and is also found in the oily matters that accompany the distillation of Scotch whiskey. From the latter source it is most conveniently obtained, though the operation is tedious and somewhat difficult.

Rutic acid is crystalline and colourless; it has an odour recalling that emitted from the skin of a goat, melts at 81° Fahr., is very soluble in alcohol or ether, is not soluble in cold water, but is slightly so in hot water. It is monobasic and forms crystalline salts termed *rutates.*

Rutic ether ($C_{20}H_{19}(C_4H_5)O_4$) separates as an oily liquid on passing dry hydrochloric acid through a solution of rutic acid in absolute alcohol. Its density is 0·862. Ammonia converts it into *rutamide.* The latter body crystallises in brilliant plates.

RUTILE. [TITANIUM.]

RUTILIN. [SALICYLIC GROUP.]

RUTINIC ACID. ($C_{12}H_8O_6$) A crystalline acid contained in the stems and leaves of rue. It is insoluble in cold water and ether, but readily dissolves in boiling water or alcohol. When an alcoholic solution of chloride of calcium is added to an alcoholic solution of rutinic acid, a bright green precipitate is thrown down.

RYE is a plant of the family of the Gramineæ, and bears naked seeds on a flat ear furnished with awns like barley. The straw is solid, the internal part being filled with a pith, which, if it causes it to be inferior as fodder, makes it more valuable for litter, and particularly for thatching. The value of the straw is often nearly equal to that of the grain. Rye grows on poor light soils which are altogether unfit for wheat, and hence tracts of light sands are often denominated rye-lands. On these soils this grain is far more profitable than wheat, which can only be raised there at a great expense of marling and manuring. The value of rye in those countries where it forms a considerable portion of the food of the labouring classes, is from two-thirds to three-fourths of that of wheat. From experiments made to ascertain the quantities of nutritious matter in rye and wheat, Thaer states their real comparative value to be as 64 to 71. It was formerly raised in considerable quantities in England, either alone or mixed with wheat, and was then called *meslin*, from the old French word *meslé*, which means *mixed.* The meslin when ground produced a very wholesome and palatable household bread, and it was thought advantageous to sow the two sorts together, from the notion that if either failed there would still be a crop of the other. This, however, was an error. No doubt the wheat would often fail on inferior soils when the rye would thrive; but the reverse was seldom or never the case; and besides the rye comes to maturity at least a fortnight before the wheat. If the soil is capable of bearing a moderate crop of wheat, it would be much more advantageous to sow one portion of a field with rye and another with wheat; and if meslin bread is desired, the two grains may be mixed in any required proportion. Excellent bread is made of two parts of wheat and one of rye ground together, with only the coarse bran sifted out.

Rye is at present raised in very small quantities in England. It is however extensively cultivated on the Continent, especially in the Netherlands, where it is the chief grain from which the spirit commonly called Hollands is distilled, which is flavoured with juniper, in Dutch called *Genever*, whence the name of *geneva* and its contraction *gin.* When malted it makes excellent beer, one bushel of rye malt being equal to at least one and a quarter of barley malt. The cultivation of rye is very simple; it is usually sown 2 or 3 bushels per acre after wheat, where the soil is light and rich, or after turnips and potatoes, in those soils which are not strong enough for wheat. As it is ripe in June or July, turnips are often sown immediately after; and by the manure produced by these, as well as their effect on the soil, a second crop of rye can be obtained the ensuing year. This is no doubt contrary to all sound theory; but such is the practice in Flanders, and they do not find that their crops diminish in consequence.

In England rye is mostly sown as a green crop, and when fed off early in spring with sheep, the land is invigorated, and will bear excellent potatoes or turnips the same year. This practice cannot be sufficiently recommended; and if the rye is sown very early in autumn, it may be fed off in October and November, when sheep-feed is beginning to fail and the turnips have not yet attained their full size, with little detriment to the succeeding spring produce.

Winter barley and winter oats have been substituted for rye as spring fodder by some farmers; but on land of moderate quality rye is generally preferred. It bears the severest winters, which is not the case with barley or oats.

The preparation of the land for rye is the same as for wheat, except that in very light soils no more ploughings are required than will clear the ground of weeds. If rye is sown after harvest, one ploughing only is usually given. It will thrive upon rich wheat soils, as well as upon lighter, and, as it throws out numerous stems in rich land, it is the more profitable as fodder, although the crop of grain might not be so abundant when the plants are too much crowded. To have as much green food as possible, the rye is always sown broadcast, three bushels at least to an acre; some sow a sack, and with advantage. It is also usually sown amongst winter tares, which the stems of the rye help to keep up from the ground: half a bushel of rye to three bushels of tares is a fair proportion; some farmers sow wheat instead of rye, as being stronger in the stem, but besides its being more expensive, it does not shoot so early as rye, nor is it so much stronger in the green stem, as is supposed. Oats are invariably sown amongst spring tares, and answer the purpose well.

There is a variety of rye mentioned by continental authors by the name of *Seigle de la St. Jean*, or St. John's-day rye, because it grows so rapidly that if sown about St. John's Day (24th June), it will be fit to mow green by the middle of September, and in favourable seasons may be fed off again in November, without preventing its giving ample feed in spring, and a good crop of grain at the next harvest. It has been introduced into England, but whether or not owing to its character not being maintained, it has not maintained its reputation. There is no doubt that there are varieties of the same kind of plants which have a much more vigorous vegetation than those commonly cultivated; and the introduction of them where they are not known is an important benefit to agriculture. The celebrated agriculturist Du Hamel du Monceau mentions an individual who had obtained, from one sowing, five abundant cuts of green rye for cattle in two years. If any green plant is cut down before the fructification is completed, it will in general throw out fresh stems; and in very rich soils its blossoming may thus be continually retarded, until the roots become too weak to force successive stems.

When the land is in good heart and clean after wheat-harvest, it may be expeditiously cultivated by means of a strong scarifier, or some similar instrument, which opens the soil several inches deep, without turning it over; and rye may be sown immediately, without using the plough. This is an immense saving of time and labour, as four or at most six horses will completely stir ten acres of land in a day, which may thus be immediately sown before the wheat is out of the field, or fit to be carried. A week gained in the time of sowing may make all the difference between a crop which can be eaten off before winter and one which will only be fit for the sheep in the succeeding spring. The weeds which may spring up with the rye will either be choked by its luxuriance, or at all events will never shed their seeds, being mown or fed off with the rye, and the roots ploughed in the next year. The large perennial roots will thus be more easily taken out by the harrows, and all the annual weeds will be destroyed.

Although the value of rye as a green crop is fully admitted in England, very little is grown for food or distillation; yet on some poor soils, where wheat and barley are now often sown with a very poor return, and at a great expense of manure, rye and buckwheat would give a much greater clear profit, and would require much less manuring: and where there are not ready means of improving the soil by claying or marling, the cultivation of rye would be found most advantageous; and, by means of sheep, very poor sandy soils might thus be made profitable.

Rye is subject to most of the diseases which attack the plants of the family of the Gramineæ, such as rust, mildew, burnt-ear, and smut-ball. These diseases are described in the article WHEAT. But there is one remarkable disease, which, although sometimes found in wheat, is much more commonly observed in rye. It is called the *ergot*, the French name of a cock's spur, which the diseased grain resembles in shape. [ERGOT.]

RYE-GRASS, sometimes called *Ray-Grass*, is one of the most common of the artificial grasses; it is of the family of the *Gramineæ* of the genus *Lolium.* There are several varieties, some annual and others perennial, some producing a strong juicy grass, and others a small diminutive plant. These varieties arise chiefly from difference of soil, climate, and cultivation. In the convertible system of husbandry, rye-grass performs a very essential part, especially the perennial sort, which, mixed with different varieties of clover and other grass-seeds, produces a rich and close herbage, which may be either mown for hay or depastured. In the course of two or three years the land is so much recruited by the extension of the roots, and by the dung and urine of the animals, that, without dung from the yard, it will produce one or two very good crops. When clover is sown to remain only one year, the annual variety of rye-grass is frequently sown with it. It adds to the weight of the hay, and the stems of the rye-grass are a good corrective to the richness of the clover, when they are given to horses in a green state; but when the hay is intended for the London market, or that of any of the great mercantile towns, the tradesmen and carmen prefer the pure clover hay, thinking it more nutritious. Those who cultivate their land on the Norfolk system have a prejudice against rye-grass, as being unfavourable to the succeeding crop of wheat. Accordingly, when they have a layer of rye-grass, instead of clover (because the clover, having been too often repeated, fails in the ends, they often take peas or beans between the rye grass and the wheat. This accords with theory; for when the rye-grass completes its fructification, even if the seed is not ripe, it has a deteriorating effect on the soil similar to that of a white crop, and therefore a leguminous crop should succeed it.

Different varieties of rye-grass have been recommended at various times; one which goes by the name of *Pacey's rye-grass* has kept its reputation as a perennial grass for a long time. The *Italian rye-grass*, well known in the south of France, in Switzerland, and in Germany, is a native of Lombardy, where it grows most luxuriantly and rapidly by means of irrigation. There is no grass which so soon forms a water-meadow; and it bears well the cold and wet winters of Britain. On rich moist land it grows most rapidly and luxuriantly. It will bear several cuttings in a season. Those who have paid attention to the cultivation of rye-grass think highly of it. It grows much more rapidly in spring than any other grass, and is so much relished by cattle, that they scarcely allow a single stem to spring up. A small space in a layer being sown with Italian rye-grass, may be distinguished in the pasture by its superior green colour and its very close pile; and the cattle will always be found there, as long as there is the least bite for them. It may be advantageously sown in autumn with the Trifolium incarnatum, and together they will give much early green food in spring. It may be a question whether this is preferable to sowing rye; but it affords a variety, and on some soils may produce earlier and more abundant feed for lambs. When Italian rye-grass is sown by itself, and allowed to go to seed, it becomes thin after the first year, from many of the plants dying off: it may therefore be prudent to mix some other kinds of grasses with it, which will supply its place where it is worn out. It is a most excellent practice to sow Italian rye-grass on old meadows and pastures, at the time when they are recruited with compost or earth. If they are well harrowed or scarified, and the rye-grass be sown before the roller goes over them, the succeeding crop of hay will be much increased in quantity and improved in quality. On water-meadows, which require renovation, this grass is invaluable, being early, rapid in growth, and very abundant when irrigated. We have seen hay made in July from a newly-made water-meadow sown with Italian rye-grass in March. This was at Mr. De Fellenberg's, at Hofwyl, near Berne, in Switzerland. No plant will more fully use abundant dressings of manure than Italian rye-grass. If richly manured and irrigated after each cutting it will yield 18 to 20 tons of green food per acre, three or four times in the year. When sown by itself 3 bushels per acre are sown broadcast in August or September, and the next year the crop will be in full bearing. A first or second cutting may be taken in the following year, and being then ploughed down a crop of late turnips or rape may be taken previous to a succeeding spring-sown corn crop.

RYE, SPURRED. [Ergot.]

RYOTS, the name by which the cultivators of the soil in Hindustan are designated. The ryots pay rent out of the produce of their land to a sovereign proprietor, and, so long as they pay the rent demanded of them, have a claim to the continued occupation of the land.

The economical condition of the Asiatic cultivator may be described as being made up of the three following circumstances:—1. He is an hereditary occupier, or, in other words, has an hereditary claim to the occupation of the land which he cultivates. 2. The amount of rent which he pays is, in practice, determined by the sovereign power. 3. There exists a number of classes intermediate between the hereditary occupier and the sovereign, all entitled to various portions of the revenue which is yielded by the land, but none having any proprietary right. The number of these intermediate classes, arising out of the tendency of all offices connected with the land to become hereditary, has contributed greatly to the ignorance prevalent among Europeans of the position of Asiatic cultivators.

Such being the general features of the economical condition of the ryot, his actual position necessarily depends most on the amount of rent paid by him to the sovereign, and the manner in which the rent is paid.

The amount of rent was fixed by the laws of Menu at a sixth, an eighth, or a twelfth of the crops, according to differences in the soil, in the degree of labour necessary to cultivate it, and in the general prosperity of districts; but in times of urgent necessity, of war or invasion, the same laws allowed the king to take even so much as a fourth. ('Institutes of Menu,' c. iii., 130; x. 118, 120.) A sixth part of the produce had come to be the uniform tax in Hindustan when the Mohammedans became its masters. ('Sacontala.') But we find in Strabo, that when Alexander invaded India, a fourth of the produce was generally taken as rent. The despotic sovereigns of the East did not long continue to observe their ancient laws, sometimes openly violating them, at other times evading them by a resort to indirect taxation. Indeed before the Mohammedan period there are instances of oppression by Hindu governments, under which the ryots were allowed to retain no more than a fifth or sixth of their crops.

The form in which the rent is paid has even a greater influence on the condition of the ryot than its amount. In ancient times the rent was always paid in produce. Whenever, in later times, it has been demanded in money, the consequences have been ruinous to the ryot, chiefly owing to the want of markets. When the ryot is compelled to pay in money, which, owing to the want of a ready market, he has a difficulty in doing, his obvious resort is to a money-lender. The money which he borrows for the purpose of relieving himself of immediate difficulty is borrowed at a high rate of interest. The immediate difficulty is thus got rid of at a great sacrifice, and the ryot becomes dependent on the money-lender. In 1860 considerable discontent was created among the ryots in Bengal by the system asserted to have been adopted by the European indigo manufacturers: these, it was at least asserted by the ryots, made agreements with the zemindars that certain portions of the land should be devoted to the cultivation of the indigo plant, to be sold to them, in consideration of certain advancements of money at a rate which was ruinous to the cultivator. The attempt to enforce these agreements by law occasioned several tumults, and the dispute is not yet (1861) settled.

The agency by means of which the rents are collected, though less important than the form of payment, has also a considerable influence on the condition of the ryot. Under the ancient Indian governments, the agents of the prince to whom districts were assigned transacted immediately with the ryots, either singly or in villages. The latter mode was the more general, by which the government levied a certain sum on each village, and left it to the villages to settle the individual quotas among themselves.

As regards the payment of rents, there were two kinds of arrangement prevailing in the villages. In some villages the land was cultivated in common, and each cultivator had a share of the produce assigned, according to certain fixed rules; these were called *byacharry* (brotherhood) villages. In others, each ryot cultivated separately his own spot of land, and paid rent for it separately: these went by the name of *putterday* (partnership) villages.

The heads of villages paid the rents collected to the heads of districts (*des adikars*); these again to the heads of larger tracts of country. The system of government detailed in the 'Institutes of Menu' enumerates lords of one town or district, of ten towns, of twenty towns, of a hundred towns, and a thousand towns. All these lords received assignments of land, and a per centage on their collections besides.

The heads of districts (*des adikars*) came afterwards to be represented by one class of zemindars, namely, those whose duties were confined to the superintendence of police. The class of zemindars however which is the best known is that class in which the duty of collecting the revenue was added to the superintendence of police. This is not the place to speak of these functionaries, or to trace the changes in their duties and position until the commencement of the British dominion. [Zemindar.]

A full and interesting account of ryot rents will be found in Mr. Jones's *Essay on the Distribution of Wealth and on the Sources of Taxation*. The reader is referred also to Mr. Mill's *History of India*, by Wilson, vol. i.

RYSWICK, PEACE OF. [Treaties, Chronological Table of.]

S

S is the chief sibilant of the English alphabet, and is employed to represent two different sounds, as in *this* and *these*. The word *sugar* would seem to justify the addition of a third sound, *sh*; but in this word the vowel *u*, so often pronounced *yu*, has modified the pronunciation of the preceding consonant. *Syugar* would easily glide into *shugar*. In the Hebrew alphabet, whence those of Europe are derived, a common symbol is employed, with and without an affixed dot, to denote *s* and *sh*. The symbol referred to has for its name a word which also signifies *tooth* or *teeth*; and if we call to mind that the so-called Phœnician and Samaritan alphabets give older forms of the Hebrew letters than those now used, it will be easily believed that the symbol in its original shape [ALPHABET] was the representation of two or three teeth: an origin which would agree with the fact that the sibilants are all formed by means of the upper teeth, and the sound *sh* by the upper and lower brought together. This explanation is confirmed by the consideration that in emitting the last-named sound the teeth are not only the sole organs employed, but more than usually exposed to view by the retraction of the lips. But for the strong evidence thus furnished by the Hebrew alphabet, the form and power of the letter might have been readily derived from an imitation of a hissing snake.

The letter *s* is subject to the following interchanges, many of which have been previously noted.

1, *s* with *d*. See D.

2, *s* with *th* and *sth*, as in the Laconian dialect of the Greek language, in which θεος, Τιμοθεος, Αθηναια, take the forms σιορ, Τιμοσεορ, Ασαναια. Hence too τυπτομεσθα, &c., readily glided into τυπτομεθα, &c. The English language formerly wrote *loveth*, *hateth*, but now prefers *loves*, *hates*.

3, *s* with *t*. Thus again the Attic forms φησι, επεσον, Ποσειδων, συ, were by the Dorians written φατι, επετον (regularly enough from the present πιπ(ε)τω), Ποσειδαν, τυ. In like manner the German words *das*, *was*, *es*, *wasser*, *hassen*, *essen*, appear in English as *that*, *what*, *it*, *water*, *hate*, *eat*.

4, *s* with *z*. Thus the Greek island Ζακυνθος was the mother city of Saguntum in Spain, and no doubt gave its name to it. In fact the manuscripts of Livy (xxi. 7), with one exception, scarcely worth mentioning, appear to have all got *Oriundi a Sagunto insula dicuntur*, not *Zacyntho*. But the most abundant evidence of the interchange is to be found in the Somersetshire dialect of our own tongue.

5, *s* with *sh*. Witness the Berlin pronunciation of all German words beginning with *st*. Moreover, the English words *sleep*, *slay*, *smear*, *snow*, have for their German equivalents *schlaf*, *schlag-en*, *schmier-en*, *schnee*.

6, *s* with *c*, *g*, and *h*. See those letters.

7, *ks* with *g*. See X.

8, *s* with *n*. See N.

9, *s* with *r*. See R.

10. *S* often appears before an initial consonant, where it is doubtful whether the older form be that with or that without the sibilant. Thus the Greek στεγω, σφενδονη, σφηξ, correspond to the Latin *tego*, *funda*, *vespa*. So σκελος and σκολοψ would be found upon close examination to be the equivalents of the Latin *crus* and *crux*, and σκαλευω to differ from *scru-ta-ri* only in the fact that the latter is a frequentative verb. Again the Greek possesses within itself the double forms σμικρος and μικρος, στρεφω and τρεπω. The English language contains numerous examples of the same variation, as in *melt* and *smelt*, *tumble* and *stumble*, *pike* and *spike*. The German as well as our own tongue not unfrequently prefixes an *s* when the Greek and often the Latin are without that letter. Thus the Greek κλει-ω (root κλεις or κλειδ), the Latin *claud-o* or *clud-o*, and *clavis*, the German *schliess-en*, and the English *shut* are all of one kin. Compare too the various forms of the words signifying *snow*.

11. The sound *sw* at the beginning of words is often degraded by the loss of the sibilant or *w*, or both. Thus to the Latin *suavis* and *suadeo* correspond the Greek ἁδυς, &c., the German *süss*, and the English *sweet*. Those who doubt the connection here assumed between *suavis* and *suadeo*, may, as regards form, compare *clavis* and *claudo*, or *viginti* with what must have been its older form, *duiginti*, while the connection in meaning will be readily established by the common comparison of *advice* with *medicine*, *unpalatable* but *salutary*, as in Lucretius (i. 935), *Sed veluti pueris absinthia*, &c. Again, *sop-or* and *somnus* (*sop-nus*) of the Latin correspond to the Greek ὑπ-νος, to the Gothic verb *in-swepp-an*, the German *schlaf*, and the English *sleep*; *socer* and *socrus* in Latin, to the Greek ἑκυρος and ἑκυρα, and the German *schwieger* as prefixed to *sohn*, *vater*, &c.; the Latin *sud-or*, to the Greek ἰδ-ος, ἱδρως, &c., to the German *schweiss* and English *sweat*; the Latin *sui*, *sibi*, *se*, to the Greek οὑ, οἱ, ἑ, although the Greek has also allied words beginning with σφ. The Latin *soror*, German *schwester*, English *sister*, have lost their correlative in Greek. Lastly this interchange will perhaps account for the fact that the river Oder has two ancient names, *Suevus* and *Viadrus*, which have been the cause of much confusion in the geography of ancient Germany. Indeed the mouth of the river is still called *Swinemünde*.

12. *Sp* is interchangeable with *ps*, *sk* with *ks*, and *sd* with *ds*. For the last we need only refer to the Doric use of σδ for ζ. Instances of the second interchange occur occasionally in Greek and Latin. Ϝιξος, the misletoe, is written in Latin *viscus*; εσχατος, ludicrously put down as a primitive in some lexicons, is of course only the superlative of the preposition εξ, for εξατος. The Latin *misceo* has for its participle *mixtus* as well as *mistus* (=*misctus*). The tendency to this interchange accounts too for the form *sescenti*, for *sexcenti* is never found in the best manuscripts of the best authors. But the Anglo-Saxon and English afford the most numerous instances of this metathesis. Thus the former language has the double forms *väps* or *väsp*, a wasp; *äpse* or *äspe*, tremulous (whence the name of the *aspen* tree); *häpse* or *häspe*, a lock (Grimm, 'Deutsche Grammatik,' p. 251); also *frosc* or *frox*, a frog; *fiscas* or *fixas*, a fish; *tusc* or *tux*, a tusk; *asce* or *axe*, cinder; *ascjan* or *axjan*, to ask (*ibid*, p. 256). Hence it will be seen that it is a mere accident if in our own tongue *axe* and *waps* have been rejected as vulgarisms in favour of *ask* and *wasp*. The provinces still prefer the *ks* and *ps*. Thus a Kentish countryman talks of a *whips* rather than *whisp* of hay. May we not in this way establish the identity in name of several of our rivers, as *Axe*, *Exe*, *Esk*, and *Usk*?

13. *S* is often lost. Inattention to this fact is the cause of much confusion in the grammars of the Greek language. Thus the neuter nouns in ος must once have had a corresponding σ in the genitive, γενες, γενεσος, &c., afterwards γενος, γενεος. Hence the retention of the *s* in the vocatives of proper names formed from neuter nouns of this class, as Διογενες, Δημοσθενες, Σωκρατες. (See 'Journal of Education,' vol. iv., 333.) Above all, the neglect of this letter in the original (as here assumed) forms of certain present tenses leads to apparent anomalies in the derived forms. Thus from κλει(σ)ω we should have without any irregularity κεκλεισμενος; from γευ(σ)μαι without difficulty γευσ-τικος, as well as the Latin *gus-tus*, *gus-ta-re*; from δε(σ)ω, δεσμος, in which the sibilant corresponds, as it so often does, to the guttural in *liga-re*, *dica-re*, and the English *tight* from *tie*. The Latin language in such cases changes the sibilant into an *r*; but even this language is not at all unwilling to discard an *s*, particularly at the end of words, as in the double forms *magis* and *mage*, *videris* and *videre*, *ipsus* and *ipse*, *puer* for *puerus*. Nay, even the neuters of adjectives seem to have lost the final *s* of the nominative in this way. At any rate *potis* is used for a neuter nominative as well as *pote*. The third person of the Latin perfect may possibly owe its occasional long quantity (*perrupīt*, Hor.; *subiīt*, Hor.; *rediīt*, Ovid, &c., &c.) to an older orthography ending in *ist*; for as the other perfects of the indicative as well as those of the subjunctive and infinitive of the active verb, to say nothing of all the passive perfects, are evidently formed by the addition of the tenses of the verb *esse*, so *perrupistis* and *perruperunt* contain in the two last syllables the almost unaltered forms of *estis* and *esunt*, and seem to justify the idea that *perrupit* is a corruption of *perrupist*, that is, *perrupest*. As to form, we might compare this corruption with what we know has occurred in the French subjunctive perfect, *fusse*, *fusses*, *fût*, that is, *fust*. The French language abounds in examples of the loss of the sibilant. Thus from the Latin *asinus*, *magister*, *noster*, *quadragesima*, are derived, first, *asne*, *maistre*, *nostre*, *caresme*, and then, according to the modern orthography, *âne*, *maître*, *notre*, *carême*, to say nothing of the silent *s* in such words as *mais*, *vous*, *isle*, *est*, &c.

SABADILLIC ACID, a name sometimes given to cevadic acid. [CEVADIC ACID.]

SABADILLINE (*Sabadillia*). A poisonous alkaloid, found along with jervine, colchicine, and veratrine in white hellebore. Its composition is not known.

SABAEI (Σαβαῖοι), a people of Arabia Felix, on the borders of the Red Sea, in the northern part of the modern Yemen. They are described by Diodorus and Strabo as the most numerous, and, together with the Gerrhaei, as the richest people in Arabia. Their country produced frankincense, myrrh, cinnamon, and balsam in abundance, but was also infested by deadly serpents. The inhabitants are represented as living an idle life, on account of the abundance of the produce of the country, but are at the same time said to have carried on an extensive commerce with Syria and Mesopotamia, both with the productions of their own country and also with those of Ethiopia, to which they sailed in boats made of skins.

The country of the Sabaei is mentioned in the Old Testament under the name of Sheba (שְׁבָא), and is spoken of as rich in incense, spices, precious stones, and gold (1 Kings x. 2; Jer. vi. 20; Isa. lx. 6; Ps. lxxii. 15), and as carrying on an extensive commerce with the other nations of Asia (Ezek. xxvii. 22; Job vi. 19; Joel iii. 8). The queen of Sheba who visited Solomon (1 Kings x. 1) is generally allowed to have come from this country, and not from Ethiopia, as Josephus relates ('Ant. Jud.,' viii. 6, sec. 5), who has confounded Sheba with Seba (סְבָא), which, as he tells us in another part of his work (ii. 10, sec. 2), was the ancient name of Meroe.

Korán, c. 34; Sale's *Preliminary Discourse to the Korán*, sect. 1; Edrisi, *Geographia Nubiensis*.)

SABAISM was the name given to a religious system which anciently prevailed to a great extent in Arabia and Mesopotamia. Sabaism is frequently confounded with the Sabaei, and is sometimes described as the religion of the latter people; but the two words are quite distinct, and are written differently in the Semitic languages. The first letter in Sabaism is Tsade (צ), and consequently the word would be written more correctly Tsabaism.

Tsabaism was derived, according to its followers, from Tsabi, the son or brother of Enoch, but is more probably derived from their worshipping the "Host of Heaven" (צְבָא הַשָּׁמַיִם). According to the Arabic writers, Tsabaism was the same as the religion of the ancient Chaldæans, and appears to have been one of the earliest and simplest forms of idolatry. They believed in the unity of the Deity, but at the same time paid adoration to the stars, or the angels and intelligences, which they supposed to reside in them and to govern the world under the supreme Deity. In the course of time images were made to represent the angels or intelligences dwelling in the stars; and the consequence of this would naturally be, that the common people would eventually worship them, as if they were gods. That the unity of the Deity was however still acknowledged in the religious system of the Tsabians is manifest from the way this religion is spoken of in the Korán; in which it is distinguished from polytheism, and is allowed to exist on the payment of tribute.

The religious books of Tsabaism were written in Syriac, and are referred to by early Arabic writers, but none of them are known in Europe. It appears that the Tsabians believed that the souls of wicked men would be punished for nine thousand years, and would afterwards be received to mercy. They were obliged to pray three times a day, at sunrise, noon, and sunset; and to observe three annual fasts, one of thirty days, another of nine, and a third of seven. They offered many sacrifices, but ate no part of them. They abstained from beans, garlick, and some other pulse and vegetables. They were accustomed to go on pilgrimage to Haran in Mesopotamia.

Tsabaism as a religious system no longer exists, but the name has been frequently, but incorrectly, applied to the Mandaites, or Christians of St. John, as they have been called. The name of Tsabians has been given to this sect by the Arabs, as they are accustomed to apply the term of Tsabians to many different religious sects. The Mandaites are found principally at the mouths of the Euphrates and near Bagdad, but they are not Christians, and the name of 'Christians of St. John' has been given to them in consequence of John being the name of the founder of their sect. From the manner in which John the Baptist is mentioned in the sacred books of the Mandaites, it appears that they supposed him to have been the founder of their religious system, and that his doctrines were corrupted by Christ. Their sacred books have been brought over to Europe; and an account of them is given by Silvestre de Sacy, in the 'Journal des Savans,' Paris, 1819; but they are written in such a mystical style that it is exceedingly difficult to understand their meaning. There are three books: 1. 'The Book of Adam;' 2. 'The Book of Yahya, or John the Baptist;' and 3. 'The Kholasteh,' or Ritual. They are written in a peculiar character, which bears great resemblance to the Syriac or Western Aramean; but the language in which they are composed more nearly resembles the Chaldaic or Eastern Aramean. The greater part of the 'Book of Adam' was published by Norberg, under the title of 'Codex Nasaræus, Liber Adami appellatus,' 5 vols. 4to, Lond. Goth., 1816-17. In the 'Book of Adam' the Christians, Jews, and Mohammedans are equally attacked; but the Mandaites appear to have adopted many things from Christianity, and they probably owe their origin to some of the Gnostic sects, which extensively prevailed in Asia.

SABBATH. The narrative in the book of Genesis of the creation of the world in six days is followed by these words: 'And on the seventh day God ended his work which he had made; and he rested on the seventh day from all his work which he had made. And God blessed the seventh day, and set it apart; because that in it he had rested from all his work which God created and made." (Gen. ii. 2, 3,) These words seem to imply that the seventh day is to be observed by all the rational creatures of God as a day of worship in acknowledgement of their Creator, and as a day of rest in imitation of his rest after the creation. We find no further mention of this ordinance during the patriarchal period, though some have supposed that there is a reference to it in the intervals of *seven* days observed by Noah in sending the raven and the dove out of the ark. (Gen. viii.) It is next met with at the time of the Exodus, under the name of the *Sabbath* (*שַׁבָּת, from שָׁבַת, to cease from labour*), where *rest* from labour is the peculiar character attached to the day. (Exod. xvi.) In the passage referred to, it appears to be spoken of as an institution already known, but this has been disputed. It was still more expressly enjoined upon the Jews at the giving of the law on Mount Sinai, when the reason assigned in Genesis for its institution was repeated. (Exod. xx. 8-11.) The Mosaic laws respecting the Sabbath are contained in the following passages, besides the two just quoted: Exod. xxiii. 12; xxxi. 12-17; xxxiv. 21; xxxv. 1-3; Levit. xix. 3, 30; xxiii. 3; xxvi. 2; Numb. xv. 32-36; xxviii. 9, 10; Deut. v. 12-15. It was a day of divine worship, though as to what that worship consisted in, we only know that there was to be an additional sacrifice besides the daily one, and a holy convocation of the people. This part of the institution was intended, like many others of the Mosaic laws, to keep in the remembrance of the people their allegiance to the true God, and to distinguish them from the idolatrous nations among whom they dwelt. (Exod. xxxi. 13, 17.) Its other feature was rest from labour, which was to be observed not only by every Israelite, but by resident strangers and beasts of burden. This rest had partly a religious character, as it was an acknowledgment of belief in the God who created the heavens and earth in six days, and rested on the seventh. For this reason a wilful violation of the rest of the Sabbath was punished by death, as it was an act of rebellion against God. A second object of this rest was, of course, to afford leisure for the religious services of the day; and a third was the refreshment of man and beast after the labour of the week. (Exod. xxiii. 12.) Moses does not however define the meaning of the term *work* in the Law; but it is evident from several passages in the Pentateuch that it was peculiarly all work of a servile character that was forbidden. Thus there is a special commandment to rest on the Sabbath in seed-time and harvest, as well as at other seasons (Exod. xxxiv. 21), and there were prohibitions against kindling fire (Exod. xxxv. 4) or preparing food on the Sabbath (Exod. xvi. 5, 22-30); the people were severely reprimanded by Moses for going out of their tents to gather manna (Exod. *ibid.*), and a man was put to death by the express command of God for gathering sticks on the Sabbath. (Numb. xv. 32-36.) This peculiar feature of the Jewish Sabbath was intended constantly to remind the people of their deliverance from their servile condition in the land of Egypt, as Moses states in his rehearsal of the Law, where the reason annexed to the fourth commandment in Exodus is omitted, and its place is supplied by the following words: "And remember that thou wast a servant in the land of Egypt, and that the Lord thy God brought thee out thence through a mighty hand and by a stretched-out arm; therefore the Lord thy God commanded thee to keep the Sabbath-day." (Deut. v. 15.) All bodily labour which was necessary for the service of God formed an exception to the statute. Thus the sacrifices were doubled on that day, and the animals had to be killed; the perpetual fire on the altar of burnt offering was to be supplied with wood *every* day; and a child was circumcised on the Sabbath, if that day happened to be the eighth from its birth. (Numb. xxviii. 3-10; Levit. vi. 8-13; Matt. xii. 5; John vii. 22-23.) It seems to be satisfactorily proved by Michaelis that the unwillingness to fight on the Sabbath, which we meet with in the later periods of the Jewish history, was never felt before the Babylonish captivity. The general spirit of the Jewish law concerning the Sabbath may be gathered from the following words of Isaiah (chap. lviii. 13):—"If thou restrain thy foot from the Sabbath, from doing thy pleasure on my holy day; and call the Sabbath a delight, and the holy feast of the Lord honourable; and shalt honour him (or it), not doing thine own ways, nor finding thine own pleasure, nor speaking thine own words:" then follows a promise. The Sabbath was reckoned, like the Jewish day in general, from sunset to sunset.

The Rabbins of later times added many superstitious and vexatious observances to the Mosaic law of the Sabbath, such as the prohibition of travelling further on that day than twelve miles, or, as it was afterwards settled, two thousand cubits, that is, about one mile. For further information on these points the reader is referred to Lightfoot ('Works,' ed. Pitman, Index, art. 'Sabbath').

The word *Sabbath* was also used by the Jews as a general name for their religious festivals, and also as equivalent to the word *week*. (Levit. xxiii. 15; Deut. xvi. 9; Matt. xxviii. 1; Luke xviii. 12.)

The first teachers of Christianity abolished the Sabbath, but introduced a similar institution in its place, the observance, namely, of the *first* day of the week as a day of rest and of religious worship, in commemoration of God's resting on the seventh day, and also more especially of the resurrection of Christ. Hence it was called "the Lord's day" (ἡ κυριακὴ ἡμέρα), just as the ordinance by which Christ's death was commemorated was called "the Lord's Supper." It has been held by many eminent divines that there is not sufficient evidence in the New Testament for such an institution, that the change of the day from the seventh to the first day of the week is an insuperable difficulty, that the Sabbath was a purely Jewish institution, and therefore that it is not binding upon Christians. The chief difficulties in this discussion appear to have arisen from a mistaken view of the question, as if it were, not whether the Christian church possesses *any* Sabbatical institution, but whether the *Jewish Sabbath* is binding upon Christians. The great fact of Christianity is the resurrection of Christ, which was effected by the power of the same God who created the world: this occurrence took place on the first day of the week; and to keep it in remembrance, we observe that day as our stated time of religious worship; or, as Bishop Horsley states the matter, "By keeping a Sabbath, we acknowledge a God, and declare that we are not atheists: by keeping one day in seven, we protest against idolatry, and acknowledge *that* God who in the beginning made the heavens and the earth: and by keeping our Sabbath on the first day of the week, we protest against Judaism, and acknowledge *that* God who, having made the world, sent his only begotten Son to redeem mankind."

In its very nature the Sabbath appears to be intended for the whole human race. As a religious institution, designed to keep in remembrance the God who created the world, it belongs equally to all men, since all are the creatures of the same God, and all are prone to forget every religious truth which is not continually and *regularly* forced upon their attention. As a day of rest, if needed at all (and it is generally granted that such rest is necessary), it is needed by every one who wears the human body. Its appointment is coeval with the creation of man, and long before the giving of the Jewish law. These facts seem to prove that it was intended to be perpetual, which appears also to be indicated by those words of Christ (Mark ii. 27), "The Sabbath was made for man," that is, not for the Jews merely, but for the benefit of the whole human race.

The Sabbath is used in the New Testament as a type of the eternal rest of heaven: "There remaineth a rest (or Sabbath-keeping, *σαββατισμὸς*) to the people of God." (Heb. iv. 9.) Some understand this passage of the Christian Sabbath.

(Michaelis, *On the Laws of Moses*, arts 194, 196; Lightfoot's *Works*, see the *Index*; Horsley's *Sermons*, 21, 23; Wardlaw, *On the Sabbath*; Hessey, *Bampton Lecture—Sunday: its Origin, History, and present Obligations*; Winer's *Biblisches Realwörterbuch*, art. 'Sabbath.')

SABELLIANS, an heretical Christian sect, which arose about the middle of the 3rd century. They were the followers of Sabellius, an African bishop or presbyter, who resided in the Pentapolis of Cyrenaica. They held that there was only one person in the Godhead, namely, the Father; that Christ was a mere man, but that there resided in him a certain energy proceeding from God, or a portion of the divine nature; and they likewise deemed the Holy Spirit merely a divine energy, or an emanation proceeding from God. They illustrated their doctrines by comparing God to the sun, the Word to its illuminating power, and the Holy Ghost to its warming energy. They were successfully opposed by Dionysius of Alexandria, but continued for a long time to be an important sect. (Lardner's *Credibility* and *History of Heretics*; Neander's *Kirchengeschichte*; Mosheim's *Ecclesiastical History*.)

SACBUT (*Saquebute*, Fr.) the name formerly given in England to the TROMBONE, which see.

SACCHARIC ACID ($2HO,C_{12}H_8O_{14}$). When sugar is gently heated with nitric acid of specific gravity 1·25, and the liquid subsequently boiled and evaporated, a colourless, deliquescent, sticky mass is obtained, to which the name of saccharic acid has been given. It is only slightly soluble in ether, but very soluble in alcohol or water; has a disagreeable acid taste, and has not yet been obtained in a crystalline condition.

Saccharic acid is isomeric with mucic acid. Like the latter acid, it is bibasic, forming, with bases, salts that are mostly crystalline. The neutral *saccharate of potash* contains ($2KO,C_{12}H_8O_{14}$); the acid salt having the composition ($KO,HO,C_{12}H_8O_{14}$), and occurring in acicular or oblique prismatic crystals.

SACCHARIMETRY. A generic term for certain operations undertaken with the view of ascertaining the quantity of sugar present in any matter that may contain it.

Saccharimetry is frequently performed upon solutions which are known to contain cane (ordinary) sugar only, the object being merely to ascertain the amount present. In such a case it is only necessary to take the specific gravity of the liquid by a hydrometer, and then refer to a previously prepared table of densities and per-centages. If Baumé's hydrometer be used, the degrees of specific gravity marked on its stem indicate the following centesimal proportions of sugar:—

Degrees.	Sugar per cent.	Degrees.	Sugar per cent.	Degrees.	Sugar per cent.
1	1·8	13	23·7	25	46·2
2	3·5	14	25·6	26	48·1
3	5·2	15	27·6	27	50·0
4	7·0	16	29·4	28	52·1
5	8·7	17	31·5	29	54·1
6	10·4	18	33·4	30	56·0
7	12·4	19	35·2	31	58·0
8	14·4	20	37·0	32	60·1
9	16·3	21	38·8	33	62·2
10	18·2	22	40·6	34	64·4
11	20·0	23	42·4	35	66·6
12	21·8	24	44·3		

1° Baumé corresponds to sp. gr. 1·007; 10° to sp. gr. 1·070; 20° to 1·152; 30° to 1·245; 35° to 1·299; &c.

If a liquid contain other substances besides cane-sugar, the test of specific gravity is of no value. In such a case advantage may be taken of the fact that syrup causes right-handed twisting in a ray of plane polarized light, to an extent exactly proportionate to the amount of sugar in solution. The saccharine fluid is placed in a long tube having opaque sides and transparent ends; and a ray of homogeneous light, polarized by reflection from a black glass mirror [POLARIZATION OF LIGHT], is sent through the liquid and optically examined by a plate of tourmaline, Nicol's prism, or other polarizing eye-piece. Attached to the eye-piece is a short arm which traverses a circle divided into degrees. The eye-piece and arm are previously so adjusted that when the ray is no longer visible the arm points to the zero of the scale of degrees. The saccharine solution, however, so twists the ray as to again render it visible; and the number of degrees which the eye-piece has to be rotated before the ray is once more invisible is exactly proportionate to the strength of the solution. The value of the degrees having been ascertained by direct experiment and the results tabulated, a reference to the table at once indicates the per-centage of sugar in the liquid under examination. Grape-sugar also possesses the property of dextro-rotation, but less powerfully than cane-sugar; moreover the former variety does not, like cane-sugar, suffer inversion of the direction of rotation on the addition of hydrochloric acid to its solution: an operation that furnishes data for ascertaining the amounts of cane and of grape-sugar, or of crystallisable and non-crystallisable sugar, present in a mixture. In using the polariscopo-saccharometer, it is convenient to use tubes of uniform size, and always to operate at the same temperature.

Cane-sugar is readily converted into grape-sugar by boiling for two or three hours with dilute solution of sulphuric acid, and the grape-sugar may then be estimated by the depth of colour which results on boiling it with solutions of caustic soda or potash; comparison being made with standard coloured solutions prepared from known quantities of grape-sugar. The quantity of grape-sugar, and indirectly of cane-sugar, may also be determined by the amount of its solution which is required to be added to a given volume of a standard alkaline solution of tartrate of copper and potash, before complete precipitation of the copper (as suboxide, Cu_2O) is effected. The standard solution referred to is known as Fehling's, and is thus prepared:—1 ounce of crystallised sulphate of copper, 3 ounces of bitartate of potash, 1½ ounces of pure carbonate of potash, and 14 or 16 ounces of a solution of caustic soda of sp. gr. 1·12 are mixed together, and water added until the whole measures 15,160 grains: 200 measures of this solution contain an amount of copper that is perfectly precipitated by one grain of grape-sugar ($C_{12}H_{12}O_{12}$). In using Fehling's solution, a temperature approaching the boiling point should be maintained, and the saccharine liquid should be slowly added from a graduated burette. By either of the above processes the separate amounts of cane and of grape-sugar in a mixture of the two may be ascertained by two operations; one performed before boiling with dilute acid and the other after: the quantity first indicated will be the grape-sugar, and that, being subtracted from the numbers obtained in the second experiment, gives the proportion of cane-sugar. One-eighteenth of the latter number must, however, be deducted; the equivalent of grape-sugar being higher by that amount than cane-sugar.

SACCHAROMETER, an instrument used principally in the operations of brewing, and making sugar. It serves to indicate the density of the liquid extracted from malt, or the degrees to which the juice expressed from the sugar-cane is concentrated previously to undergoing the process of crystallization. An instrument of the like kind, called a *lactometer*, is employed to exhibit the density of milk. Both of them are formed on the same principle as the hydrometer [HYDROMETER], and such instruments are sometimes comprehended under the word *aræometer*, or *gravimeter*. Their general use is to determine, when extreme accuracy is not required, the specific gravities of liquids which are of greater density than water, and even those of solid bodies in small quantities. [SPECIFIC GRAVITY.]

SACCHULMIN, the brown substance produced by the action of sulphuric acid upon sugar.

SACER MORBUS (Ἱερὰ Νόσος), a term applied apparently by the ancients to more than one disease, as Athenæus ('Deipnosoph.,' lib. vii. § 33, p. 289) speaks of *τὰς ἱερὰς καλουμένας νόσους*, and Heraclitus is said by Diogenes Laertius ('De Vit. Philosoph.,' lib. ix., cap. i., § 6 and 7) to have called Arrogance by that name: *τήν τε οἴησιν ἱερὰν νόσον ἔλεγε*. Generally however it is merely used as one of the numerous names of epilepsy [EPILEPSY], and this is the explanation given by Hesychius and Suidas *in voc.* It is first used by the author of the treatise Περὶ Ἱερῆς Νόσου, 'De Morbo Sacro,' which is published among the works of Hippocrates (tom. i., p. 587, ed. Kühn), though it was probably written by one of his successors in the Dogmatic school. (See Gruner, 'Censura Libr. Hippocr.,' Vratislav., 1772, 8vo., § 44, p. 162; and Ackermann, 'Hist. Liter. Hippocr., ap. Fabricii Biblioth. Gr.,' ed. Harles, and Kühn's 'Hippocr.,' tom. i.) The term is also found in Aretæus ('De Caus. et Sign. Diuturn. Morb.,' lib. 1., cap. 4). Theophanes Nonnus ('Epit. de Curat. Morb.,' cap. 36), Artemidorus ('Oneirocrit.,' lib. ii., cap. 12, where see Reiff's note 35), and others. The meaning of the term is obscure and uncertain, and several derivations of it are mentioned by Aretæus (*loco cit.*): "There is," says he, in Dr. Reynolds's translation, "a sort of ignominy too in the character of epilepsy, for it seems to attack those who offend the moon, and hence the disease is termed 'sacred;' or it may be from other reasons, either from its magnitude (for what is great is 'sacred'), or from the cure not being in the power of man but of God, or from the notion that a demon has entered the patient, or from all put together, that it has been so called." The author of a treatise 'De Morbo Sacro,' seems to have considered the origin of the term to have arisen from the belief either that this disease proceeds more immediately from the anger of the gods, or that it is more wonderful than others, or that its cure depends more entirely upon divine assistance; as he refutes all these opinions at some length. (See also Galen, 'Comment.' vi., in Hippocr. 'Epidem.,' lib. vi., tom. xvii. B., p. 341, ed. Kühn.) The other reason that is given, namely, "the magnitude of the disease," is supported by the author of the 'Schol. MS. in Gregor. Nazianz. in Bastii Excerptis,' quoted in Gaisford's Suidas: *τινὲς ἱερὰν ἑτέραν τινὰ λέγουσι νόσον τῷ ὀνόματι τούτῳ, τὴν ἐπιληπτικὴν οἶμαι· ἱερὰ δὲ αὕτη κυριώτερον ἂν κληθείη, διαφέρουσα πασῶν τῇ κακώσει· ἐπεὶ καὶ μέγα τὸ ἱερὸν τοῖς γλωσσηματικοῖς εἴθισται καλεῖσθαι.* It is also indirectly supported by the analogous expressions *ἱερὸν μένος Ἀλκινόοιο* (Homer, 'Odyss.,' lib. vii., v. 167), *ἱερὸς ἰχθύς* (see Athenæus, 'Deipnosoph.,' lib. vii., § 17-20, pp. 282-4), and especially by the anatomical name *ἱερὸν ὀστοῦν*, "os sacrum," of which this seems to be the most probable interpretation. Cælius Aurelianus gives the following interpretations: "Appellatur Epilepsia '*sacra* passio,' sive quod divinitus putetur immissa; sive quod sacram contaminet animam [which is supported by Apuleius, 'Apolog.,' p. 58, ed. Prisc.]; sive quod in capite fiat, quod multorum philosophorum judicio sacrum templum est partis animæ in corpore natæ [which is the reason given by Theophanes Nonnus, *loco cit.*]; sive ob magnitudinem passionis, majora enim vulgus *sacra* vocavit." ('De Morb. Chron.,' lib. i., cap. 4. p. 291, ed. Amman.) Of all the explanations that have been proposed, perhaps that which derives the term from the disease being supposed to be under the more immediate direction of the gods is the most likely to be the true one, both as being the most ancient and also as being that which Galen preferred: it is also indirectly confirmed by two popular names mentioned by Leo in his 'Synopsis Medicinæ, lib. ii., cap. 2 (ap. Ermerins, 'Anecd. Med. Gr.,' Lugd. Bat., 8vo., 1840), namely, *δαίμων* and *σεληνιασμός*. If this is not the real meaning of the term, it must have been applied "*ob magnitudinem passionis*," for none of the other derivations bear the slightest marks of probability.

SACK, a Spanish wine of the dry kind; in French, *Vin sec.* It is the same wine which is now named Sherry. Falstaff calls it *Sherris sack*, that is, sack from Xeres in Spain. Ritson supposed that the old sack of Falstaff's time was a compound of sherry, cider, and sugar; but he produced no good authority for the assertion. The chief difficulty about sack has arisen from the later importation of sweet wines from Malaga, the Canaries, &c., which were at first called Malaga, or Canary sacks; sack being by that time considered as a name applicable to all sweet wines. One of these sweet wines still retains the name of sack. It is little used, but being proverbial for sweetness, it has caused some misunderstanding as to the original dry sack.

SACRAMENTS and TRANSUBSTANTIATION. The Christian Sacraments are not merely certain high forms, but the highest acts of church membership. For the Christian Church being but the outward visible representation of the internal fellowship of the faithful with Christ, and with one another; this twofold element of the church is most fitly corresponded to by the institution of external visible actions, intended to express an internal spiritual effect or grace. Such are the Sacraments, a term used to express "Sacramentum," by which the Greek *mysterion* is rendered in the old Italic versions, and also in the Vulgate.

With regard to the number of the Sacraments, as is well known, two opinions are current among Christian communities,—the Greek and Romish Churches holding the number of seven, while all other Catholic bodies limit the number to two. The history of this difference may be briefly stated as follows. The term Sacrament was applied by the Fathers to the mysterious doctrines of religion, as the Trinity, the Incarnation, and, in some instances, to the ordinances of religion in a wide sense. In a certain sense the seven-fold system of the Church of Rome may be considered as an abatement of the lax terminology of some of the Fathers. The title of sacraments is by her limited to seven actions—baptism, or the sign of our spiritual birth; the eucharist, in which our spiritual life is nourished; confirmation, for the strengthening of the same; penance, for the restoration of the lapsed; extreme unction, as a preparation for death; matrimony, for maintenance of the race of mankind in general; and orders, for that of the race of God's ministers.

Without entering into the controversy on this subject, it will be sufficient to observe that the number of seven, as asserted by the Church of Rome, is very far from being sanctioned by the uniform ascent of ecclesiastical practice. Antecedently to a very modern synod (that of Florence) the number of seven had never been positively settled.

The two sacraments then, to which, in the judgment of all Catholic bodies (save the Greek and Romish communions) the number is properly limited, are those of baptism and the Lord's supper. It is asserted that on the basis of two Jewish rites of recognised typical import our Lord established, by direct command, those two sacraments, of which alone the authority is unquestionable. An indirect argument in favour of this more restricted view may be drawn from the Romanist statements respecting the relative value of the several sacraments. For although the authorities of that church are consistently anxious to prove the entire number of seven to be equal in rank, the dignity which they directly attribute to the eucharist, and that which they cannot withhold from baptism, may be in some sort alleged as an involuntary assent to the doctrine of the opposite party.

The principal feature of the scheme of salvation providentially offered to man is faith in the Saviour; that is, that through Christ a path is opened to heaven. The eye of this Christian faith is not confined exclusively to the doctrine, or the person, or the sufferings and death of Christ; but it comprises within its range the entire system. It consists in a perfect devotion to Jesus; in an internal union with him, and spiritual imitation of him, in which man appears as a new creature, alike as regards knowledge, feeling, and action. The symbols of this faith, and the acts by which an obligation to it is expressed, are the two Christian sacraments—baptism and the Lord's Supper. Baptism will be found fully treated under that head.

The various opinions respecting the exact import and appropriate benefits of the Lord's Supper are of high antiquity. A history of these will be found in the article COMMUNION. The difficulties connected with the question are increased by the general adherence to the words of Scripture, observable in the liturgical formularies. The non-existence of a dogmatical theology during the first ages of the Church is well known, which renders it unnecessary to look for exact scientific definitions throughout that period. But, concurrently with the uniformity of practice, there is to be found a three-fold variety of interpretation, corresponding with the peculiar views of what may be considered the three principal schools of early Christian theology.

The Church of Asia Minor, as also some great Origenists in the West, professed views of the holy eucharist which the Church of Rome and the Lutheran have (to a certain extent,) pleaded as the sentiments of antiquity supporting their own. Such were those of Ignatius, Justin Martyr, Irenæus, Hilary of Poitiers, Cyril of Jerusalem, Gregory of Nyssa, Ambrose, Chrysostom, and Theodoret. The common point of agreement among these writers is the communion of the body and blood of Christ in a high spiritual sense *generally*. But a considerable difference of statement regarding details is observable among them. For example, some expressions of Cyril of Jerusalem are directly and strongly opposed to the tenet of transubstantiation, which Gregory of Nyssa is not unfairly quoted as supporting.

The views of the Church of North Africa, as expressed by Tertullian, Cyprian, and Augustine, differed as a whole from those just named. The African doctors may be considered as regarding the eucharist as an active and efficacious symbol.

A third party, that of the school of Alexandria, applied in some measure its usual allegorising views to this sacrament. But even in the absence of all approach on the part of these Fathers to corporeal views, a leaning to the sentiments of the first-mentioned party is observable in some portions of their writings.

Each of the many designations by which this sacrament was known until the close of the 4th century, bore some reference to the original object of its institution. This may be traced throughout the various expressions—breaking of bread, communion, Lord's supper, eucharist, oblation, commemoration, and passover. Ecclesiastical antiquity cannot be adduced with fairness in support of the literal interpretation applied by a large body of Christians to the words used by our Lord in His institution of the sacrament. John of Damascus, the principal writer of the Eastern Church, maintained (it is true), on the authority of some of the Fathers, a literal change of the bread and wine into the body and blood of Christ. The figurative interpretation put upon the words of Christ by a council at Constantinople in A.D. 754 was denied at the second council of Nice in 787, when it was ruled that the sacred symbols are not figures or images at all, but the real body and blood. Theophylact and Euthymius Zigabenus coincide with John of Damascus. But it was reserved for the Western Church to carry out into its remote consequences the doctrine of a material change, which, in common with her Eastern sister, she ultimately came to maintain. This doctrine was maintained during the 9th century by Paschasius Radbert more precisely and authoritatively than before. He was opposed, however, by Rabanus Maurus, and Ratramn or Bertram (whose sounder and more scriptural views many centuries later found an echo in our own Ridley), and also by the suspected ingenuity of Scotus Erigena.

Various instances of opposition to the doctrine of transubstantiation subsequently occurred; but, supported by authority like that of Sylvester II. (the famous Gerbert), it continued to gain ground. During the 11th century it had become an article, to dissent from which was heretical; although a doctrine substantially the same with that held by the Anglican Church at the present day was preached by doctors such as Alfric, and although an archbishop of Sens, Leutheric, advocated opinions regarding the eucharist similar to those which involved Berengar of Tours in controversy with Lanfranc, and drew upon him the hostility and condemnation of popes and councils.

Among the numerous controversies connected with the different theories on the subject, the more modern opinions are marked by a tendency to regard the eucharist as a purely symbolical rite. For transubstantiation Luther substituted a corporal local presence, commonly called consubstantiation. There appears an inconsistency in the obstinacy with which Luther contended for his theory. He had abandoned the sacrifice of the mass and the theurgic pretensions connected with the real presence which made this dogma of such importance to the Church of Rome. Luther's great object was to preserve this sacrament from being degraded by the same unspiritual *subjective* views (as he conceived) with which it was menaced by Carlstadt and his party. This evil would be best remedied by a bold assertion of the *objective* dignity of this sacrament, divested of the superstitious additions with which it was encumbered in the Church of Rome. Hence the Lutheran doctrine of the eucharist. What has been said will suffice to show how ungrounded is the charge sometimes brought against Luther—that he threw away the substance while he retained the shell. But his tenacious adherence to scholasticism in this respect contrasts strangely with his uncompromising hostility to that philosophy respecting the fundamental dogma of justification by faith. Zwingli, on the other hand, together with a corporal and local presence, rejected all notion of a spiritual presence and graces. But the opinions of Calvin shortly afterwards superseded the colder ones of Zwingli, many of whose followers, to quote from Waterland, abandoned the "notion of naked signs and figures to the Anabaptists of those times, where they rested, till again revived by the Socinians, who afterwards handed them down to the Remonstrants."

The point of divergence between the adherents of Luther and Calvin respecting the eucharist may be stated thus:—The former party held, according to the earlier Augsburg Confession and the Form of Concord, that the body of Christ was contained in, with, and under, the sacramental bread. The others held the doctrine only of a real spiritual feeding on the body of Christ, which took place in the faithful contemporaneously with the reception of the outward elements. In the opinion of Waterland, "Calvin refined upon Zwingli's scheme, steering a kind of middle course between the extremes. He appears to have set out right, taking his ground with good judgment; and had he but built as carefully upon it afterwards, no fault could have been justly found."

Bishop Lloyd considered that the Anglican doctrine was borrowed from that of Calvin. The third and fourth clauses of the twenty-eighth article, respecting the manner and means after and by which the body of Christ is taken in that sacrament, would seem to support this view. But the words of Waterland may be fairly quoted as expressing briefly the opinion held by the majority of Anglican teachers on this subject: "Our divines who came after Calvin had some advantage in point of time, and a greater still in the rule or method which they pitched upon as most proper to proceed by. The sum of all is, that sacramental or symbolical feeding in the eucharist is feeding upon the body broken and the blood shed under the signs and symbols of bread and wine; the result of such feeding is the strengthening or perfecting our mystical union with the body glorified, and so, properly speaking, we feed upon the body as dead, and we receive it into closer union as living, and both in the eucharist when duly celebrated."

SACRIFICE, an offering made to God, in which the thing offered is wholly or partially destroyed. It is generally supposed that sacrifices were instituted immediately after the fall of Adam, when God made with him what is called "the covenant of grace;" and that on this occasion the sacrifice was partly an atonement for Adam's sin, partly a ratification of the covenant. This supposition is founded on the fact that God clad Adam and Eve with the skins of beasts; and since animal food had not yet been given to man, it is thought that these beasts must have been slain as sacrifices. (Genesis, chap. iii.) In the next generation we meet with sacrifices as a divine appointment. (Gen. iv. 1–5.) All over the world sacrifices have been found in some form or other, which is another proof of their great antiquity. Their chief object is to atone for sin [Atonement]; but they have also been offered as the means of gaining the favour and assistance of God, and of expressing submission and gratitude to him. They may be divided into two classes, bloody and unbloody. In the heathen world human sacrifices have been very generally prevalent, apparently from a notion that human life is the most precious thing that can be offered to the divine Being. Sacrifices form a large part of the Jewish law. Christians believe them to be abolished since the death of Christ, since, as Paul argues in his Epistle to the Hebrews, that was the one great sacrifice which has for ever made atonement for the sins of men.

SACRILEGE is "the felonious taking of any goods out of any parish-church or other church or chapel." By the common law it was a capital offence, though the offender seems to have been entitled to the benefit of clergy at the discretion of the ordinary. But even if it were not clergyable at the common law, yet the statute 25 Edw. III. c. 4, "De Clero," comprehended this as well as other crimes, and gave "the privilege of holy church to all manner of clerks, as well secular as religious." Afterwards, by the statutes of 23 Hen. VIII., c. 1, and 25 Hen. VIII., c. 3, revived by 5 & 6 Edw. VI., c. 10, all persons not in holy orders were excluded from the benefit of clergy who on an indictment for *robbing* any church, chapel, or other holy place were convicted, stood mute, or peremptorily challenged more than twenty of the jurors; and by 3 & 4 Will. & Mary, c. 9, the same consequences followed upon their outlawry. It seems, however, that no sacrilege came within these statutes which was not accompanied by an actual *breaking* of a church, &c. But by 1 Edw. VI., c. 12, all persons in general were deprived of their clergy for the felonious taking of any goods out of any parish-church or other church or chapel in all cases, except that of challenging more than twenty jurors: and by 3 & 4 Will. & Mary, c. 9, upon such a challenging, as well as upon conviction, &c., upon an indictment, whether in the same county wherein the sacrilege was committed, or in a different one. It seems that sacrilege was the only felony at common law which deprived the offender of the privilege of sanctuary.

The present state of the law of sacrilege depends on the statute 7 & 8 Geo. IV., c. 29, s. 10, which enacts that "if any person shall break and enter any church or chapel, and steal therein any chattel, or having stolen any chattel in any church or chapel, shall break out of the same, every such offender, being convicted thereof, shall suffer death as a felon."

By 9 Geo. IV., c. 55, s. 10, the same protection was extended to meeting-houses and all places of divine worship.

By the statute 5 & 6 Will. IV., c. 81, the punishment of death was abolished, and transportation for life or for any term not less than seven years, or imprisonment with or without hard labour for any term not exceeding four years, was substituted in its place. These penalties were again altered by 6 Will. IV., c. 4, which limited the term of imprisonment to three years, and gave to the court a discretionary power of awarding any period of solitary confinement during such term. But now, by the statute 7 Will. IV. and 1 Vic. c. 90, s. 5, no offender may be kept in solitary confinement for more than one month at a time, or three months in the space of one year. And see 16 & 17 Vict. c. 99.

SADDLERY. [Leather Manufacture.]

SADDUCEES (Σαδδουκαῖοι), one of the four Jewish sects at the time of Christ. The Rabbinical tradition makes them the followers of Sadoc, a disciple of Antigonus Sochos. They denied the existence of any spiritual beings except God, and believed that the soul died with the body, and therefore that there was no resurrection. (Matt. xxii. 23; Acts, xxiii. 8.) In consequence of this disbelief in a future state of rewards and punishments, they were inexorable in punishing crimes. They rejected the doctrines of predestination and providence, maintaining that men were left to determine their own course without assistance or hindrance from God. They rejected the traditions of the Pharisees, and adhered to the text of the Mosaic law. They have been accused of rejecting all the books of the Old Testament except the Pentateuch; but the passage of Josephus, on which this charge is founded, does not sustain it. Though inveterately opposed to the Pharisees, they united with them against Christ. During the period to which the New Testament refers, though less numerous and less popular than the Pharisees, they seem to have been superior by the eminent men they had in the Sanhedrim, and some of their body were high-priests, as Caiaphas and Ananias. It seems that they considerably modified their opinions in progress of time, and received the doctrines of angelic beings and of the resurrection; so that at last they were only distinguished by their rejection of tradition, from which circumstance they obtained the name of Caraites, in the 8th century A.D. (Josephus, 'Antiq.,' xiii. 5, 6, 9, 10; xviii. 1, 4; Jahn's 'Biblical Antiquities; Winer's 'Biblisches Realwörterbuch.')

SAFES. [Fireproof Construction; Fireproofing.]

SAFETY LAMP. [Lamp, Safety.]

SAFETY-VALVE. An opening in a steam-boiler loaded with a certain weight, which is raised by the steam when the latter acquires a certain elasticity, so that a portion of the steam escaping relieves the boiler from internal pressure and danger of bursting. In the locomotive engine the boiler is furnished with two loaded valves, one of which is beyond the engine-man's control, and is called the *lock-up valve*, while the other, at a somewhat lower pressure, can be regulated by him, by means of a lever and spring balance. By making the aperture large enough, the whole of the steam can be let off as soon as it is generated, by which means the engine is put out of work. The valve may be loaded by means of a weight placed upon it, or by means of a lever with an adjustable weight according to the pressure required.

SAFFLOWER, or *Bastard Saffron*, is noticed under the botanical name of the plant [Carthamus *tinctorius*, in Nat. Hist. Div.] yielding it. This plant has been cultivated in Eastern countries from the earliest times, both on account of the oil expressed from its seeds and for the colouring matter procurable from its flowers, which in their dried state form the safflower of commerce. The oil of the seeds of carthamus was valued by the ancients as a laxative medicine, and is still employed by the Asiatics for the same purpose, as well as for external application. It is most extensively used as a lamp-oil. The seeds are eaten by some birds, especially parrots, whence they are called "graines de perroquets." The plant is, however, chiefly cultivated on account of its flowers, not only in China, India, and Egypt, but also in the south of Europe. That from China is the most valued, and the Bengal safflower considered the most inferior. This might be remedied probably by selecting and sowing only the seed of the most highly coloured flowers, and then adopting the Chinese method of gathering the crop when the flower is in the highest perfection, and only picking off the upper and coloured parts of the floret, instead of the whole floret, of which the lower part is whitish-coloured. Besides this, careful drying is essential to the preservation of the colour, or, as Mr. E. Selly has recommended, gradual drying "in close chambers with some organic substance, or perhaps with hot sand;" but the natural heat of the climate in darkened chambers would probably be sufficient.

SAFFRON consists of the dried stigmas of the *Crocus sativus*, a plant native of Greece and Asia Minor, but extensively cultivated in Austria, France, Spain, and also formerly in England. The Sicilian saffron is said to be the produce of the *Crocus odorus*, but both in ancient and modern times this sort has been little esteemed. England is chiefly supplied from France and Spain; that of Spain being preferred. In Germany, however, Spanish saffron is not in such repute as the Austrian, great pains being taken in the cultivation of the plant in that country. The cormi or stems are subject to the attacks of a fungus, *Sclerotium Crocorum*, by which they are extensively destroyed. When the flowers expand, and are thoroughly open under the influence of the sun, the stigmas, of which there are three, are plucked out, a portion of the style remaining attached to them, and spread upon paper, to be dried either by means of portable kilns over which a hair-cloth or fine sieve is stretched, or in a room by the sun. The stigmas are from an inch to an inch and a half long, narrow and roundish where they are attached to the style, but spreading out and club-shaped towards the apex, which is truncate. The upper part is of an orange or brownish red; the part of the style termed feminelle is yellowish. The stigmas have a penetrating, aromatic, and, when in large quantity, stupefying odour, and a bitter aromatic taste; by mastication the mouth and saliva are rendered yellow. By long internal use of them many of the secretions acquire a yellow colour. The stigmas of *Crocus Pallasii*, *C. longiflorus*, and *C. Serotinus*, are not so long as those of the genuine saffron crocus, and are altogether devoid of the strong odour. They and many other articles, such as the florets of the safflower (*Carthamus tinctorius*), those of the marigold (*Calendula officinalis*), slices of the flowers of the *Punica granatum*, and pieces of dried flesh, are used to adulterate the true saffron. The saffron of English commerce is generally very pure; but the high price offers much temptation to sophistication, which might be diminished by collecting the stigmas of the *Crocus vernus*, which are little inferior in colour or potency to those of the autumnal crocus. According to Mr. Pereira, one grain of good saffron contains the stigmata and styles of nine flowers; hence 4820 flowers are required to yield one ounce of saffron. Saffron was formerly met with in two forms, *hay saffron* and *cake saffron*, the former is now alone in demand, the latter being entirely an artificial compound of the florets of the safflower, gum, and some other materials. Genuine saffron is often moistened with oil, which gives an appearance of freshness to old and dry saffron; but the mixture is easily detected. Saffron consists of a volatile oil, in variable proportion, which is heavier than water, of polychroite, which is a compound of a volatile oil and a bitter red substance (or polychroite properly so called), gum, and other principles. [SAFRANIN.]

Saffron had formerly many powerful and important properties mistakenly assigned to it. On the Continent it is much used as a condiment with food. In England it is used in medicine, chiefly as a colouring principle. It is also employed as a pigment for water colours, and as a dye, for which purpose considerable quantities are imported from France.

SAFRANIN. (*Polychroite.*) Alcohol takes up from the aqueous extract of saffron a peculiar colouring matter to which these names have been given. On the evaporation of the alcohol it forms an uncrystallisable mass, very soluble in water and alcohol, but almost insoluble in ether and in oils. Its composition has not been ascertained.

SAGAPENUM, said by Willdenow to be yielded by *Ferula Persica* which no one regards as certain, though it is generally believed to be furnished by some species of Ferula. The plant (or plants) which yield it grow in Persia and other regions of the East. It is procured in the same way as assafœtida. It occurs either in tears or irregular masses, of a dirty brownish colour, containing in the interior white or yellowish grains. It is difficult to break (unless when very old), is tenacious, and not easily powdered, except in winter. It has the same alliaceous odour, but less powerful, as assafœtida, with a nauseously bitter, acrid, guttural taste.

It consists of, in the 100 parts, according to Pelletier :—

Resin	54·26
Gum	31·94
Bassoria	1·0
Peculiar substance	0·60
Acidulous malate of lime	0·40
Volatile oil, including loss	11·80
	——100·

Brandes found only 3·73 per cent. of volatile oil, and less resin than in the above; and Geiger says it has less volatile oil than assafœtida; while Pelletier's analysis gives nearly three times as much. The resin, by the action of hot hydrochloric acid, becomes first reddish, then blue, and at last brown. The resin appears to be a mixture of two kinds, one soluble, the other insoluble, in ether. Formerly there were two kinds of Sagapenum in commerce, but at present only the worst of the two is met with. It is said to be adulterated with assafœtida and bdellium. Its action on the human system is the same as that of assafœtida and other fetid gum-resins. [ASAFŒTIDA.]

SAGITTA (the Arrow). This constellation is one of the old ones, and is situated over the back of AQUILA. In CONSTELLATION it is stated that Sagitta is a part of Aquila in Aratus; but this, though very commonly stated, is erroneous, as is noticed by Grotius in his notes on Aratus; though the edition of Grotius himself countenances the error in the plates. Grotius traces the mistake to Germanicus in his Latin version.

SAGITTARIUS (the Archer), one of the constellations of the zodiac, the figure of which is that of a centaur drawing the bow, and situated below Aquila, between Scorpius and Capricornus: it must not be confounded with CENTAURUS. The mythological account of this constellation is very meagre, and confirmatory of the reason given in CONSTELLATION why the Greeks could not have been the first to give names to the constellations. Hyginus can find no more illustrious mortal to fix in this part of the heavens than one Crotus, the son of Eupheme, the nurse of the Muses; but it is worth noting that he says many (in his time) denied that the original figure was that of a centaur.

SAGO, a word signifying, in the language of the Papuas, *bread*, since it constitutes the staple article of food of the inhabitants of the Eastern Archipelago and other parts where the plants which yield it grow. It is not a seed, as sometimes supposed, but the farina from the stem of several palms and palm-like vegetables. The old stems of *Caryota urens* also yield goods ago. Sago is a variety of starch, prepared by the plant for the use of the flowers and fruit, and is most abundant just before the evolution or appearance of the spadix or flower-bud, which is known by a whitish dust transuding through and covering the leaves. At this time the stem is cut down, near the base, and then divided into pieces of five or six feet in length. "A part of the outer hard wood is then sliced off, and the workman, coming to the pith, cuts across the longitudinal fibres and the pith together, leaving a part at each end uncut, so that when it is excavated there remains a trough, into which the pulp is again put, mixed with water, and beaten with a piece of wood; the fibres, being then separated from the pulp, float at the top, and the flour subsides. After being cleared in this manner by several waters, the pulp is put into cylindrical baskets made of the leaves of the tree; and, if it is to be kept some time, those baskets are generally sunk in fresh water to keep it moist, for the pulp will keep long if preserved from the air, but if exposed it presently turns sour." (Forrest's 'Voyage to the Moluccas.')

The quantity yielded by one tree is prodigious. Five or six hundred pounds are not an unusual produce for one tree; and as the vegetation still remains after being felled, a stem again springs up, which goes through the different stages of growth till it is fit for the axe.

The flour or powder is rarely imported, granulated sago being the state in which it is commonly brought to Europe. To bring it into this state from the flour, it must be moistened and passed through a sieve into an iron pot (very shallow) held over a fire, which enables it to assume a globular form. Thus all our grained sago is half baked, and will keep long. Of this granulated sago there are two varieties, the common or brown sago, and pearl sago. The latter is in small, hard, horny, or semi-transparent grains, about the size of a pin's head; the former are in large grains, about the size of the grains of pearl barley. Both are inodorous, and have an insipid taste. They swell in cold water, and are nearly thoroughly soluble in boiling water, so as to form a thick starch-like solution, which may be used as a pudding, or prepared in other ways as an article of diet for children and invalids, if a farinaceous diet is required. Care must be taken to distinguish a factitious sago prepared from potatoes. This can only be done by the microscope.

SAIL, a quantity of canvas attached to the yards or stays of a boat or ship in order to receive the impulse of the wind, and thus give motion to the vessel. The depth of a sail is capable of being diminished at pleasure, according to the force of the wind, by means of the reef-points.

The principal sails of large vessels can be placed at right angles to the direction of the keel of the ship, and this position is given to them when the vessel goes before the wind; in other cases the same sails may, by means of the braces, be placed obliquely to the keel. The sails which are attached to the ship's stays, and the sails of boats or small vessels, are generally in a vertical plane passing through the keel; a certain degree of obliquity to that plane may, however, be given to them at their lower extremities if necessary. Sails are strengthened by ropes, called bolt-ropes, sewn along their edges in order to prevent them from being easily torn by the action of the wind.

When a vessel is in still water, the pressure of the wind against the sails overcomes its inertia, and motion takes place in some direction. The motion goes on increasing by the accelerative power of the wind; but at the end of a certain time the resistance in an opposite direction, both of the air against the sails and hull of the ship, and of the water against the latter, becoming equal to the accelerative power of the wind, the ship acquires a terminal or uniform velocity, and in this state (neglecting the resistance of the air) there may be said to be an equilibrium between the pressure of the wind against the sails and of the water against the vessel.

The principal problem connected with the motion of vessels on the water has for its object the determination of the relation between the velocities of the wind and of the vessel; and its solution consists in finding algebraic expressions for those pressures, and making them equal to one another. But many practical difficulties present themselves in investigating that relation; for the pressure of the wind is modified by the form which the sail assumes when acted upon, by the obliquity of the wind's direction to the general plane of the sail, and by the interference of one sail with another, by which interference the wind may be partly intercepted, or currents may be produced in directions different from the general direction of the wind. The resistance of the water is also greatly modified by the form of the ship's hull, and by the direction of its motion with respect to the line of the keel. These difficulties cannot be removed; therefore the results of mathematical researches concerning the motion of ships can only be considered as very remote approximations to the rules which should guide the practice of the seaman. And in order to simplify the problem, it is necessary to suppose that the ship is furnished with only one sail, whose area is such that the action of the wind upon it may be equivalent to the efficient action of the wind upon all the sails. The *centre vélique*, as it is called by foreign writers, or the centre of pressure or *effort*, must also be supposed to be at the centre of gravity of the sail. That part of the ship's surface which is resisted by the water must moreover be represented by a plane surface whose area is such that this resistance shall be equivalent to the efficient action of the water on the ship.

The pressure of the air perpendicularly against a plane surface equal to one square foot is usually estimated at [illegible] lb. avoirdupois, the surface pressed being at rest, and the wind moving with a velocity equal to one foot per second, or about 0·68 mile per hour; also the resistance of water against a like surface and moving with an equal velocity is estimated at 1·5lb. The pressure or resistance, by the laws of hydrodynamics, varies with the square of the velocity; and, from the resolution of forces, it may be shown [AERODYNAMICS] that the effective force with which a fluid strikes a plane surface obliquely, when estimated in a direction perpendicular to the plane, varies with the square of the sine of the inclination to the plane. This, however, is only an approximation for practical purposes, its insufficiency arising from want of allowance for the accumulation of force depending on the shape or curved surface of the sail; and, from the experiments of Bossut, D'Alembert, and Condorcet, it appears to hold good only for inclinations between 50° and 90°. The experiments of Smeaton indicate that the pressures vary nearly with the sine of the inclination, when the latter is between 50° and 60°; at greater inclinations the pressure is some fractional power of the sine, and at very small inclinations it approaches nearly to the square. But the following formula of Smeaton gives the effective velocity very nearly as

$$= \text{V} \sin\theta^{1\cdot842 \cos.}$$

From the experiments of Dr. Hutton it is found that at inclinations between 50° and 90° the pressures vary nearly as the sines of the inclinations.

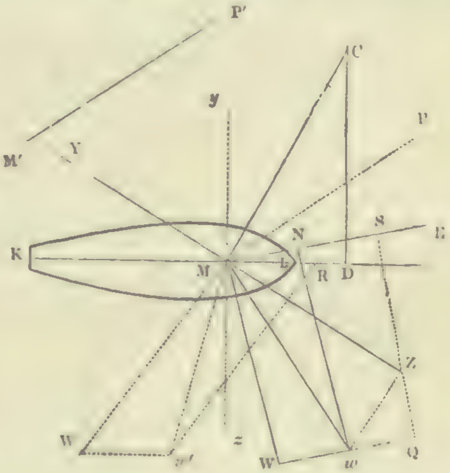
In determining the pressure of a fluid against the surface, which is in motion, it must be observed that, by the laws of the collision of bodies, the efficient velocity of impulse is to be expressed not by the absolute, but by the relative velocity of the impelling power. Hence, when the wind and ship are moving in the same direction, the effective velocity is the difference, and when they are moving in opposite directions, it is the sum of their several velocities. It must also be observed that the force of the wind and the reaction of the water are to be considered as taking place in horizontal directions, and that the effective pressure of the wind on a flat sail is in a direction perpendicular to the plane of the sail, whatever be the position of the latter and the direction of the wind.

Now when a ship sails before the wind in still water, if we consider the sail as a plane surface at right angles to the keel of the ship and to the direction of the wind; representing the pressure of the air on a square foot, when the velocity is one foot per second, by P, and the pressure of the water on a square foot with an equal velocity by P'; also putting V for the velocity of the wind, and V' for that of the ship, both being expressed in feet per second; A for the area of the sail, and A' for that of a vertical section through the immersed part of the ship taken perpendicularly to the keel; the equation of equilibrium will evidently be

$$\text{A}.\,\text{P}.\,(\text{V}-\text{V}')^2 = \text{A}'.\,\text{P}'.\,\text{V}'^2;$$

and from this equation V' may be easily found. It follows from the same equation that, when the other terms are constant, $\dfrac{\text{V}'}{\text{V}-\text{V}'}$ varies with $\sqrt{\text{A}}$, or the velocity of the wind in the sail is to the velocity of the ship as unity is to the square root of the surface of the sail.

But while the plane of the sail is supposed to be perpendicular to the keel of the ship, let the direction of the wind be oblique to both, and let the force of impulse perpendicularly to the sail be proportional to the square of the sine of the inclination of the wind to the sail; then, if K L be the keel, M the place of the mast, $y\,z$ the position of the yard, and $\text{W}'\text{M}$ represent the direction and velocity of the wind, we shall have $\text{W}'\text{M}.^2 \sin.^2 \text{W}'\text{M}z$ for the force of impulse with which a particle of air acts on the sail. This value of the impulse is, however, correct only at the moment before the ship begins to move; for, let the ship be advancing in the direction K L with a velocity such that the sail moves parallel to itself from M to R, while a particle of air would move from W' to M if the ship were at rest,—it will be evident now that a flag at M, which, when the ship is at rest, would have its plane in the direction $\text{W}'\text{M}$ produced, being carried by the motion of the ship from M towards L, would be acted on by the particles of air coming against it, as if it were resisted by forces parallel to M R and tending from R towards M; therefore the forces parallel to $\text{W}'\text{M}$ and R M being respectively proportional to those lines, the flag will by the composition of forces take the direction $w'\text{M}$, the diagonal of the parallelogram $\text{W}'\text{R}$. This is the efficient direction of the wind, and its velocity may be represented by that diagonal, when that of the wind in its true direction is represented by $\text{W}'\text{M}$: consequently the impulse of the wind perpendicularly to the plane of the sail must be represented by $\text{P}.\text{A}.\,w'\text{M}^2.\,\sin.^2 w'\text{M}z$. By this impulse motion is produced in the ship in the direction of its keel, and the whole expression may be made equal to $\text{A}'.\text{P}'.\text{V}'^2$, the former expression for the resistance of the water. The values of $\text{W}'\text{M}$ and of M R, that is, V and V', the absolute velocities of the wind and ship, and also the angle $\text{L M W}'$ being known, the value of $w'\text{M}$ may be computed.



When the direction of the wind is not coincident with the line of the ship's keel, its power to impel the ship forward will be increased by placing the sail in some oblique position, as Y Z. In this case let M C, perpendicular to Y Z, represent the velocity with which, if not resisted by the water, the ship would move by the action of the wind. Then, by the resolution of motions, letting fall C D perpendicularly on K L, M D and D C will represent the velocities in those directions; and, in the case of equilibrium between the actions of the wind and water, the resistance of the latter against the side of the ship perpendicularly to the keel will be to that against the bow, parallel to the keel, as C D to D M, or as tang. ∠ C M D to radius. Let A'' be the area of a vertical section through the immersed part of the ship in the direction of the keel, and A', as before, the area of the vertical section perpendicularly to the keel; also suppose that, in consequence of the reaction of the water, the ship's motion, instead of being in the direction M C, should be in some other, as M E. Then, V' representing the velocity of the ship in this direction, and the resistance of the water being supposed to be proportional to the square of the velocity and square of the sine of the inclination, we have $\text{P}'.\text{A}''.\text{V}'^2 \sin.^2 \text{E M D}$ for the resistance of the water against the ship's side, and $\text{P}'.\text{A}'.\text{V}'^2 \cos.^2 \text{E M D}$ for the resistance against the bows. Therefore

$$\tan.\ \text{C M D} : \text{radius} :: \text{A}'' \sin.^2 \text{E M D} : \text{A}' \cos.^2 \text{E M D};$$

consequently, the ratio of A′ to A″ being supposed to be known, the value of Z M D, that is, the ship's lee-way, might be found. If Z M D = 45°, and the ratio of A″ to A′ be assumed to be as 12 to 1, the lee-way will be found to be 16° 6′; and if Z M D = 30°, the lee-way will be 20° 49′. But experiment alone can determine this element, for, with equal velocities and equal quantities of sail, it varies in different ships; and, in the same ship, with the velocity, and the disposition and quantity of the sail.

Let M N represent the velocity of the ship in the direction M E; then w M, the diagonal of the parallelogram W N, will represent the efficient velocity of the wind in that direction, W M being the true direction of the velocity, and letting fall on Y Z the perpendicular w Z, this last line will represent the velocity perpendicularly to the sail. Therefore the force of the wind in this direction will be proportional to $w Z^2$; then drawing w Q parallel to M E, to meet Z Q drawn through Z perpendicularly to M E and w Q, we have Z w Q equal to the complement of Z M E, and consequently $w Z^2$ being resolved in the direction M E or w Q, becomes $w Z^2$ cos. Z w Q, or $w Z^2$ sin. Z M E. But w Z varies as sin. ∠ w M Z; therefore the force of the wind to impel the ship in the direction M E is proportional to $\sin^2$. w M Z sin. Z M E; and the force of impulse being proportional to the square of the velocity produced by it, it follows that the velocity of the ship will vary with sin. w M Z $\sqrt{}$ sin. Z M E. Now making the differential of this expression equal to zero, considering w M E as constant and Z M E as variable, it will be found that this product is a maximum when ∠ w M E is so divided that tan. w M Z : tan. Z M E : : 2 : 1, or that sin. (w M Z − Z M E) = $\frac{1}{3}$ sin. w M E.

In Maclaurin's 'Fluxions' (art. 912) there is given an investigation of the angle W M Z, between the true direction of the wind and the plane of the sail, when the velocity of the ship's motion in M E is a maximum. The general expression is complex, but when the direction of the wind is perpendicular to the ship's course we have tan. W M Z =

$$\sqrt{\left\{2+\frac{9}{4}\frac{v'^2}{v^2}\right\}}+\frac{3}{2}\frac{v'}{v};$$

v′ being the velocity of the ship and v that of the wind.

Therefore, if the velocity of the ship were very small, we should have tan. W M Z = $\sqrt{2}$ nearly, or W M Z = 54° 44′ nearly. But, on making v′ equal to $\frac{1}{4}$, $\frac{1}{3}$, and $\frac{1}{2}$ of v, we obtain for ∠ W M Z the several corresponding values 61° 27′, 63° 26′, and 66° 58′. It may be observed also that, if both ∠ Z M E and v are given, the velocity of the ship will be a maximum when the angle W M Z is a right angle, or when the sails are perpendicular to the true direction of the wind.

In the same work (art. 917) there is given the investigation of an equation from which may be determined the angle Z M E, between the plane of the sail and the line of the ship's motion when the velocity is a maximum; and from that equation it is inferred (art. 919) that, if the wind is perpendicular to the sail, the velocity is the greatest (provided the velocity of the ship before the wind be not less than one-third of the velocity of the wind) when sin. Z M E : radius : : $(v-1)^{\frac{2}{3}}$: 1·5874; the velocity of the ship being expressed by unity, and v, the true velocity of the wind, by a multiple of that velocity. It may also be inferred from the same equation, that if the velocity of the wind be such as to cause the velocity of the ship to be greater than one-third of itself, the ship will sail faster when the course is oblique to the wind than when coincident with its direction.

The force of the wind, which is denoted by P. A. $w M^2 \sin.^2$ w M Z sin. Z M E, being made equal to P′. A′. V'^2 (which will express the resistance of the water, if A′ represent the area of the immersed section of the ship perpendicularly to M E), the value of V′, the velocity of the ship, might from thence be obtained; and from the expression of that value it may be seen that, while the other terms remain the same, the velocity of the ship varies with the relative velocity of the wind and ship, with the sine of its inclination to the plane of the sail, and with the square root of the area of the sail. Hence also, when the velocity of the wind and both the area and position of the sail are constant, the velocity of the ship varies with sin. w M Z; that is, with the sine of the angle made by the apparent direction of the wind with the plane of the sail. It may be inferred from the general equation, that, by sufficiently increasing A and the angle w M Z, the velocity (V′) of the ship may be made to exceed w M, which is that of the wind.

If it were required to find the course of the ship and the position of the sails, so that the ship might recede most rapidly from any point of danger, as from a lee-coast situated, for example, in the position indicated by M′ P′, at right angles to w M, the direction of the wind; we must imagine M P to be drawn parallel to M′ P′, that is, perpendicular to w M. Then, the velocity of the ship in the direction M E being represented by sin. w M Z $\sqrt{}$ sin. Z M E, let this velocity be resolved into the direction perpendicular to M P; that is, let it be multiplied by sin. E M P: the ship will recede most rapidly from M′ P′ when the expression sin. w M Z. sin. E M P $\sqrt{}$ sin Z M E is a maximum. On making the differential of this expression equal to zero, we shall find that the velocity perpendicularly to M P is the greatest when ∠ w M P is divided so that the tangents of the angles w M Z, Z M E, and E M P are to one another as the numbers 2, 1, and 2. If the velocity of the ship be very small, we shall have ∠ w M E, or its equal Z M P, = 54° 44′ nearly; and ∠ w M Z = 35° 16′ nearly. And since receding at right angles from a line M′ P′, when that line is perpendicular to the direction of the wind, is an advance towards the wind; it follows that the above value of w M Z will indicate the position which the sail should have with respect to the wind, in order that the ship may get to windward with the greatest possible velocity. If the velocity of the ship be taken into consideration, the angles w M E and w M Z will, as before, be modified by the relation between the velocities of the ship and wind.

Since the lee-way, which a ship always makes when her sails are oblique to the direction of the wind, destroys the equality of the reaction of the water which would take place on the two bows if her movement were in the direction of her keel, and gives rise to an excess of pressure against the lee-bow; it follows that in these circumstances the ship's head is constantly forced to windward, and that the tendency of the ship to turn on the axis of the rotation is so much greater as the bows are more acute. To oppose, in some measure, this tendency, the quantity of sail in front of the centre of rotation, is greater than that which is behind it; but, notwithstanding such disposition, it always requires some movement of the rudder to complete the counter-action.

SAIL-MAKING. The canvas used for sails is a very stout material, woven in England or Scotland from Russian hemp, and purchased in the form of rolls called *bolts*, each bolt containing about 40 yards of canvas 24 inches wide. There are six or seven different qualities of this canvas, according to the size and position of the sail to be made; and each quality has a particular number attached to it, and must have a certain weight per square foot. Thus, in the Royal Navy, a bolt of No. 1 canvas, containing 38 yards, must weigh 44 lbs.; whereas No. 7 weighs only about half as much: the intermediate numbers having intermediate weights.

As the canvas is only two feet wide, many breadths are required to form a large sail. The mainsail of an East Indiaman contains nearly 700 yards of canvas; while the whole suit of sails for such a ship requires as much as 9000 yards. As the sails vary much in shape, considerable tact is required in cutting up the canvas so as to avoid waste. The art of the sail maker consists not only in seaming up the numerous breadths, so as to give the requisite dimensions to the sail, but also in strengthening the sail by sewing rope to its edges. The seaming and sewing are effected with large three-sided needles, of seven or eight different kinds, which are threaded with sewing twine having from 200 to 400 fathoms to the lb. The skeins of twine previous to being used are dipped into a trough, containing melted tar, grease, and oil, which is afterwards dried. The sail-maker has a thumb-stall and a palm-thimble, for protecting his right hand. His stitches have a regulated degree of closeness, on which his rate of payment in part depends; there are usually about 100 stitches in a yard. The overlapping of the breadths is an inch or an inch and a half. Besides the seaming, sundry small pieces of canvas are stitched to the sail to strengthen it in various directions; and the edge-rope or bolt-rope is sewn on with great firmness. So skilfully is the canvas marked out and cut up by a master sail-maker, that in the 9000 yards for the forty sails of a large ship, there will not be more than three or four yards actually wasted.

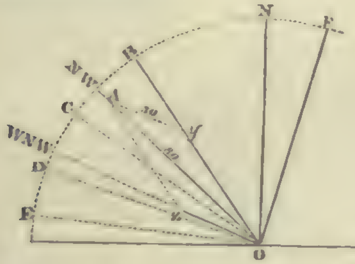
The *storm sails* patented in 1844 by Mr. Archibald Trail are made in the usual manner, but are subsequently strengthened by sewing to their surface a number of canvas bands about an inch broad, with cords woven in them, such bands being secured at their ends into the bolt-ropes, or cords forming the boundaries of the sail, and carried diagonally across the surface of the sail at an angle of 45° with the seams, and at a distance of about three feet from each other. Two sets of bands are used, crossing the sail in opposite directions, one set being attached on each side of the canvas. By this simple contrivance the strain is so equalised as to render tearing less probable than with an ordinary sail; while, if any injury be inflicted, the rent is confined within the narrow limits of one of the diamond-shaped compartments into which the sail is divided by the protecting bands.

SAILINGS; or THE SAILINGS. The various modes in which the calculations of a ship's true course are conducted, have already, under the head RECKONINGS AT SEA, been referred to individually, as forming part of a seaman's "day's work," or *dead reckoning* as it is called; distinctive of such portions of his work as depend on observation of the heavenly bodies. In this article it is proposed to review the peculiarities of the sailings with reference to the great problem of the accurate navigation of the surface of a sphere.

Under the word NAVIGATION the subject has been treated rather as the practice of a general system; and its details have been partly referred to under the terms COMPASS, GREAT-CIRCLE OR TANGENT SAILING, LONGITUDE AND LATITUDE, &c. It remains then to treat of the relative values of the various means of estimating a ship's true position by means of certain operations called "sailings."

In considering first the nature of the most simple form of navigation, namely, plane sailing, but which is only available for small spaces on the earth's surface and in low latitudes, the following diagram will assist.

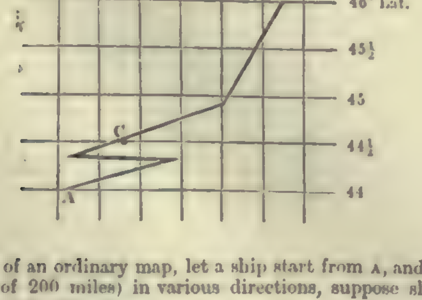
Suppose for example, a ship bound to a port bearing true N.W., distance 80 miles or knots. Her average general velocity to be 8 knots per hour. A W.N.W current to be setting at the rate of 3 miles per hour. The terrestrial deviation on the compass to be 2 points westerly. The ship's local attraction upon the average course to be 16° westerly: while, moreover, the wind being north-easterly (true), and the ship being nearly close-hauled, we should allow about 1 point leeway. It is obvious that with so many elements of disturbance an approximate course must be selected before starting. Now, the unscientific ship-master would guess at his course, and if he found himself by subsequent observation or otherwise, setting either to leeward or the reverse, would so vary his course as to attempt by time-losing experiments to finally reach his destination; while the complete navigator would probably proceed thus:—He would either roughly calculate his true course, having in his mind's eye the following figure, or would construct the figure itself, as under:—



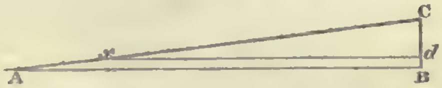
Let O represent the ship's position at starting, and A the intended port. It is usual to take the current as a course and distance. We get the approximate distance by saying in this case 8 : 80 : : 3 : 30. O z will, therefore, represent in position and magnitude the current course and distance; compounding the ship's bearing and distance from her intended port, and the set of current, as *forces* [COMPOSITION], we get the parallelogram O z A y, and the ∠ A O y (composed with the N.W. line O A) will be the course, which measured from north would be about N. 32½° W., or by calculation, thus: O A being given as 80, and bearing N.W., and O z being given 30, bearing W.N.W., the ∠ z O A would = 2 points: hence in the triangle A O y we have given the two sides and included angle O A y (= z O A) to find the rest by trigonometry. From this it would be seen that starting from O, in the direction O y, would, as influenced by the current, carry the ship along the resultant O A to its intended port at A, were no other influence at work. But perhaps the most difficult portion of a mariner's duty is to clear his course from compass errors. To continue the example:—after projecting the 2 points variation westerly from B to C, and the 16° W. by local attraction [LOCAL ATTRACTION] from C to D, and the 1 point leeway (westerly) from D to E, we find that the correction for leeway and compass error amounts in this case to the correction B E, which, measured to the eastward of O B, gives the true course which must be steered by compass to be O F, or instead of about N. 32½° W., it should be about N. 18° E.

Whatever method of sailing we adopt, the above mode of correction is indispensable; but with the exception of terrestrial deviation, the amount of correction to be applied depends chiefly on the judgment, and perception, and vigilance of the navigator.

Middle latitude sailing has already under the article RECKONINGS AT SEA been partially explained as regards its application to practice; its *principles* will now be briefly considered. The meridians of the globe meeting at the poles, the parallels of latitude diminish in magnitude as they recede from the equator; but as each parallel circle must contain 360° of longitude, it evidently follows that the term degree of longitude is one of only relative value, depending on the latitude at which it is situated: and when we estimate longitude by turning (as the phrase is) departure into longitude, the assumption of its latitude is either obtained by using middle latitude sailing, which adopts a mean between the latitude left and that arrived at, or by Mercator's sailing, which in most cases is more accurate. The questions will be better understood from the following figure:



On a portion of an ordinary map, let a ship start from A, and after a day's run (say of 200 miles) in various directions, suppose she finds herself at B. By middle latitude sailing the mean between the paralle left and that reached would be $\frac{44° + 46°}{2} = 45°$, but if we measure along the track sailed, it will be found that one-half the distance sailed would actually fall to the southward of 45°, or at C; hence the inaccuracy of middle latitude sailing in finding the longitude. Of course the remedy for this would be to divide the track into portions, and find the difference of longitude for each. When near the equator where the meridians are not so convergent, middle latitude sailing may be used with very trifling error; but Mercator's sailing is at such places less accurate, because, as the following figure will show, a small error in the course would make a large error in longitude.



In this, C x would be the distance run, and the angle A C B the course, d x the departure, and A B the difference of longitude.

Parallel sailing is used when the ship makes no difference of latitude, but sails upon a parallel of latitude. It is only preferred for its simplicity, because in "running along a parallel" the distance is the departure, and the true course is east and west: but it is at the expense of accuracy, for a ship thus sails along an arc of a circle instead of its chord, although at first sight the reverse appears to be the case. It is however certain, that the shortest distance between two points on the surface of a sphere is the arc of a great circle, the plane of which passes through the earth's centre. Now, if in the following *fig.* 1, we draw on a right sphere, *ab*, equal to the parallel of 40°, and assume the points thereon at *c* and *d*, the nearest distance between them will appear to be *c d*. This may be shown to be incorrect if the parallel of 40° be drawn in *fig.* 2 on gnomonic projection, where the chord *c e d* connects the two points and is their nearest distance; hence the curve *c e d*, in *fig.* 1, is the nearest distance between the points *c* and *d*, because its plane would pass through the centre, while the plane of *c d* would be parallel to it. But these errors might be avoided altogether by the use of great circle sailing, and especially as Mr. Saxby has rendered the finding of a great circle course more easy than even the Mercator's; as already fully explained under GREAT CIRCLE, OR TANGENT SAILING.

Fig. 1.

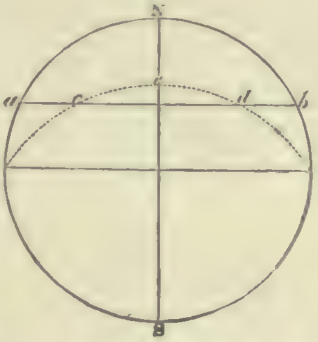


Fig. 2.

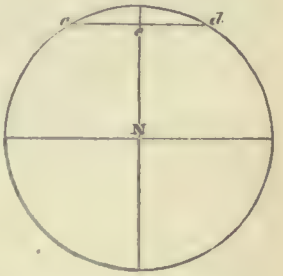
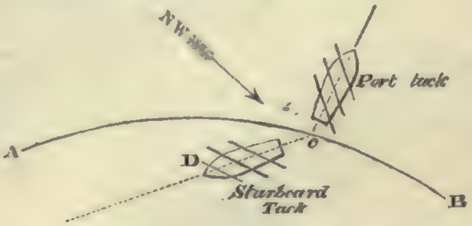


Windward sailing is a term used in connection with great circle sailing, by which is implied the advantage taken of the changes in the course of a ship when sailing upon the tangents of a great circle, and is such that a considerable saving of distance in a voyage may be effected when a ship is opposed by contrary winds, in determining on which "tack" to sail with reference to the great circle track itself. For example, suppose that a ship starting from B towards A on a great circle track, as drawn upon a Mercator's chart, meets at C with the wind N.W.; if her captain puts her upon the port tack, he absolutely sails away from his proper course, while by keeping her on the starboard tack, as at D, he sails in a direction nearly parallel to it.



Oblique sailing is merely a term applicable to those problems in which no right angle appears in the projected triangle. It is a mere term of oblique trigonometry, such as occurs in setting off one's position by cross bearings of objects whose relative bearing and distance from each other are well known.

Composite sailing was so called, and ably illustrated by Mr. Towson, but the subsequent invention of the Spherograph has rendered it as a sailing quite unimportant.

Having thus explained the usual resources of the navigator in his work of calculation under *systems* of progression, the subject may be viewed from another point. The comparative steadiness of large steamers on the ocean, and the greater advantages they possess in their partial independence as to the direction of the wind, might seem to be a relief to the ship-master; such is, however, counterpoised by the extreme difficulties inherent in steam navigation, and especially in iron ships. It is true the courses of steamers are more direct and free from "traverses," but it is the question of local attraction, ever liable to vary, which needs all the vigilance of the commander. This important subject has been treated of under Local Attraction, but we may add that Professor Airy has further illustrated his previous investigation by a very valuable communication read before the Institution of Naval Architects on March 1st, 1860.

SAILORS. [Ships; Seamen.]

SAINFOIN, *Onobrychis sativa,* is a plant of the family of the *Leguminosæ,* which grows luxuriantly and spontaneously on the calcareous soils of the middle and south of Europe. It has been in regular cultivation for upwards of two centuries for the purpose of supplying fodder for cattle, either in the green state or when converted into hay. There are few plants which have more rapidly improved the value of poor, thin, calcareous soils than sainfoin; and in the richer kinds of loam, which contain a considerable proportion of calcareous matter, its value surpasses even that of broad clover, giving fully as great a return, with a much smaller expenditure of manure. The plant has a strong woody and fibrous root, which insinuates itself into the fissures of calcareous rocks, and finds moisture in the driest seasons, while its spreading fibres keep the earth from being washed down the steep slopes of the hills. Being nearly perennial, or at least of many years' duration, it binds the soil together. In favourable situations it may be made into hay twice in the year, or cut oftener as green fodder. In the most arid and exposed situations it gives at least one good crop of hay. The plant grows about two feet high, and the stem, which branches out into many compound leaves, is crowned with a beautiful spike of papilionaceous flowers. After it has been mown it shoots out rapidly again, and may be advantageously depastured by every kind of cattle or sheep. There are varieties of the plant which differ in the rapidity of their growth: the best is called in France *esparcette,* or *sainfoin à deux coupes.* From France it has been introduced into England. The duration of sainfoin depends on the nature of the soil, and the state it was in with respect to weeds when it was sown. A cold wet subsoil soon destroys the roots, whereas a free and dry one, whether rocky or gravelly, gives them vigour. Grass and weeds, which choke the crown of the plant, soon cause it to decay, as is the case with lucern. With every advantage, it may last in vigour ten years, especially if it be occasionally invigorated with a top-dressing of manure. During that time it may be cut for hay every year, taking care to cut it before the flower is faded or the seed formed; and if sheep are folded on the aftermath, the next crop will well repay the trouble. It is usually sown in spring in a crop of barley or oats, which should be sown thin in order that the sainfoin may not be smothered. The land should have been prepared by a cleansing crop, such as turnips fed off by sheep folded on them. From three to four bushels of rough seed may be sown, harrowed in, and rolled. It is not often drilled, although this method, by allowing the use of the hoe between the rows, would much strengthen the young plants, and protect them against coarse grasses, which are their greatest enemies. In the first year the sainfoin should not be fed off by sheep; and if it is mown, it should not be mown too close to the ground. The crown of the root in the young plant rises a little above the ground, and if this be bit off or cut with the scythe the plant dies. It is useful to harrow the ground lightly, to draw the earth round the roots, and to destroy the seed-weeds soon after the barley or oats are reaped. The sainfoin does not produce a large crop the first year, for some of the seeds will lie a twelvemonth in the ground before they spring up. It is in perfection after the second year, when a portion may be reserved for seed. Sainfoin hay is extremely nourishing for every kind of cattle, especially if it has been made without rain. Although it is not apt to heat in the stack, it must be put up in a very dry state; and if it has suffered from rain too much care cannot be taken thoroughly to dry it, for the water insinuates itself into the hollow stems, and is long in evaporating, so that when it feels quite dry it may yet contain much water. The mode of discovering this is to twist it strongly in the hands into a rope, when the moisture, if there is any, will ooze out. It is better to let it dry thoroughly, than, by carrying it in a hurry, to run the risk of its becoming mouldy within. In very precarious seasons it may be carried in a half-dried state, provided there be no moisture in it from dews or showers, and stacked in alternate layers with good straw. It will impart some of its fragrance to the straw, and lose none of its nutritive qualities. The same may be done with lucern or clover. The most advantageous use of sainfoin, however, is to cut it green and give it immediately to the cattle. There is little danger of their being hoven by it, for it ferments very slowly, owing to the fibrous nature of the stem. If the situation of the field admits of occasional irrigation, without danger of the water stagnating, the produce of the sainfoin will be greatly increased; and it has been known to be cut four or even five times in a season without exhausting its strength. When it begins to appear thin on the ground, and other plants seem to get the better of the sainfoin, it is time to break it up. The land will be found much improved in fertility by the sainfoin. A poor chalk or gravel, which before would scarcely repay the seed sown in it, will now, by the gradual decay of the roots and fibres of the sainfoin, produce good crops without manure. If clean, it may be ploughed up for wheat; if foul, as it is most likely to be, it may be pared and burned, and yield a crop of turnips, to be partly fed off and followed by barley. Many a poor barren tract of calcareous rock and gravel has been fertilised and raised in value by the sole effect of the sainfoin, without which it must have remained in its unproductive state.

Although a chalky soil is best adapted to the growth of sainfoin, it may be sown with advantage in all light calcareous loams, provided the substratum be sound and dry. On very rich deep moulds lucern is a more profitable crop; but sainfoin will thrive where lucern will fail, and it is particularly adapted for poor dry soils.

There is nothing peculiar in the manner in which sainfoin is made into hay. It should not be shaken about too much, but treated as clover is, for fear of injuring the flower and breaking off the leaves. The swathe should be merely turned over when dry on one side, and then, as soon as it is dry through, it should be put into small cocks, turned once or twice when the dew is off the ground, and carried to the stack as soon as it is sufficiently made. It should take a good heat in order to make it compact, but without acquiring too dark a colour. Experience alone can teach the exact time when it should be stacked. When it is left for seed, it should be examined carefully after the blossom fades. The lower pods will be filled with ripe seed before the blossoms at the top of the spike of flowers are withered or the seed formed in them. If the sainfoin were left standing till these seeds were ripe, the lowest would be shed; but by cutting it at a proper time these may be preserved, while most of the latter will ripen in the straw sufficiently to vegetate when sown. Rainy weather is very injurious to the seed crop; a fine time should therefore be selected, if possible, even at the risk of a smaller crop. The produce varies from three to five, or even six, sacks per acre. It is easily threshed out, and this operation is often done on a cloth in the field, when the weather permits. It is readily done by a threshing-machine, and winnowed like corn. On the whole, there are few plants the cultivation of which is so advantageous as that of sainfoin on the limestone soils on which it thrives best.

SAINT, derived from the Latin "sanctus," through the French "sainct," properly signifies a holy or pious person, and is so used in the Christian church. From the commencement of the Christian religion, great veneration was always shown to persons remarkable for their holiness or piety, and their memory was cherished after their death. In course of time it became the custom to implore departed saints to assist the living by their prayers and intercessions with the Deity; and as man has in all ages felt the want of a mediator between himself and the Deity, the practice of praying to saints increased rapidly, and superstition multiplied the number of such mediators to so great an extent, that it was at length found necessary to put some restraint upon the practice. It was accordingly decreed by the ecclesiastical councils in the 9th century, that no departed Christian should be considered as a saint to whom prayers might be addressed, until the bishop in a provincial council, and in the presence of the people, had pronounced him worthy of that honour. Even in that century many divines thought that it was proper that the decisions of bishops and councils should be confirmed by the consent and authority of the pope, who was regarded as the supreme and universal bishop. It was not, however, till the following century that any person was sainted by the bishop of Rome alone; and this honour was first conferred on Udalric, bishop of Augsburg, by John XV. Shortly afterwards the privilege of declaring departed Christians to be saints was confined to the pope; and the creation of saints was distinguished by the name of "canonisation."

The invocation of saints in the Roman Catholic church is frequently stigmatised as idolatry; and the Church of England condemns the Romish doctrine on the subject as "a fond thing vainly invented, and grounded upon no warranty of Scripture, but rather repugnant to the word of God." (Article xxii.) In this, as in any other case of religious controversy, it is right to take the account of the doctrine from the persons who believe in it, and not from a statement of their opponents. Thus Bellarmine says, "It is not lawful to ask of the saints to grant to us, as if they were the *authors* of divine benefits, glory, or grace, or the other means of blessedness. This is proved, first, from Scripture: 'The Lord will give grace and glory.' (Psalm lxxxiv.) Secondly, from the usage of the church; for in the mass prayers and the saints' offices we never ask anything else but that at their prayers benefits may be granted to us by God. Thirdly, from reason; for what we need surpasses the power of the creature, and therefore even of saints; therefore we ought to ask nothing from saints beyond their impetrating from God what is profitable to us. Fourthly, from Augustine and Theodoret, who expressly teach that saints are not to be invoked as gods, but as able to gain from God what they wish. However, it must be observed, when we say that nothing should be asked of saints but their prayers for us, the question is not about the words, but the sense of the words. For, as far as words go, it is lawful to say, 'St. Peter, pity me, save me, open for me the gate of heaven;' also, 'give me health of body, patience, fortitude, &c.,' provided that we mean 'save and pity me by praying for me;' 'grant me this or that by thy prayers and merits.' For so speaks Gregory Nazianzen, and many others of the ancients." ('De Sanct. Beat.,' i. 17.) The doctrine of the Roman Catholic church is explicitly stated in the council of Trent: "Though the church has been accustomed sometimes to celebrate a few masses to the honour and remembrance of saints, yet she doth not teach that sacrifice is offered to them, but to God alone, who crowned them; wherefore neither is the priest wont to say, I offer sacrifice to thee, O Peter, or O Paul, but to God." (Sess., 22.)

The Lives of the Saints have been written in the 'Acta Sanctorum,' 51 vols. fol. [BOLLANDUS, JOHN, in BIOG. DIV.]; and in Alban Butler's 'Lives of the Saints,' 12 vols. 8vo.

SAL MIRABILE, a name formerly applied to sulphate of soda.

SAL PRUNELLA. [POTASSIUM. *Nitrate of Potash.*]

SALE is that transaction by which the ownership of property is transferred to the buyer, in consideration of a money payment by him, or on his behalf, to the seller. Such transfer of ownership may sometimes be made, although the property does not belong to the seller; as in the case of sales in open market, which are valid, though made by parties wholly without title to the property, or authority to sell it; and sales by factors and agents duly authorised. Under the present head it is proposed to treat only of the law relating to the simple act of sale, it being assumed that the parties to the sale are legally qualified to effect it. Persons in certain conditions are by law in some cases restrained and in others disabled from buying and selling, but these restrictions and disabilities form no part of the law of sale; they belong rather to those branches of the law, such as infancy, bankruptcy, insolvency, coverture, lunacy, alienage, &c., which create and define them.

Generally, all things may be the subject of sale; but there are some exceptions,—such are a mere title to lands of which a party is not in possession, a presentation to a living actually vacant, the pay of a naval or military officer, and some other things.

Property is distributed under the two heads of real and personal property, which differ materially in many respects; and the modes of effecting the sale of each of these kinds of property likewise materially differ. Some incidents, however, are common to a sale both of real and personal property.

No sale is valid so as to be capable of being enforced unless—

1st. The parties to it act with good faith;

2nd. Unless there is consent in each of them; and,

3rd. No sale is valid the subject of which is illegal, or which involves an illegal transaction, or has for its object an illegal act.

With respect to the first principle, it is a maxim of the common law that fraud vitiates all contracts. The fraud may be, with respect to the property, the subject of sale, either of a positive character, such as wilful misdescription of it in some material particular by the seller, or negative, such as a designed concealment of defects and incumbrances. In these cases the contract of sale cannot be enforced, notwithstanding express stipulations that the property shall be taken with all its faults, or that misstatements shall not invalidate the sale, but shall be provided for by compensation.

What is a material particular, will of course depend upon the subject-matter of the sale and the circumstances of the case. A misdescription of the situation of an estate, a statement that a public-house which was bound by covenant to purchase beer of a particular brewer was a free public-house, that a long leasehold estate was freehold, have been held to be material. Under this head may be adduced as an instance the employment of more persons than one to make false biddings at an auction on behalf of the seller. Such persons are commonly called puffers. One such person may lawfully be employed to protect the interests of the seller by merely buying in the property at a predetermined sum. But the bidding of more than one has the effect of inducing an incorrect opinion as to the value of the estate, and such bidding, being fraudulent, invalidates the sale. In like manner fraud on the part of the buyer will have the same effect; as where he prevents other persons from purchasing by fraudulently misrepresenting the nature of the property, or attempts to obtain possession of it with a design not to pay for it; or where, when negociating the sale, he knows himself to be insolvent, or makes payment by cheques or bills which he knows will not be honoured, &c. These are instances of fraud which is intended to operate only on one of the parties to the sale. But the same effect may be produced where the fraud is intended to operate on other persons not parties to the sale; as where a sale is attempted to be made by a seller for the purpose of defrauding his creditors. If in such case the buyer participate in the fraudulent intention, the sale will be invalid. In an action at law, the question whether fraud has existed is to be determined by the jury.

2. There must be consent in each of the parties to the sale. This rule involves the proposition that each must be a free and intelligent agent: no sale therefore can be valid where either of the parties was under coercion by violence or imprisonment, or bodily fear, or was lunatic, or idiot, or utterly intoxicated. Again, in order that a buyer may be a legally consenting party to a sale, he must be truly informed in all material particulars as to the property which is the subject of sale. This must be understood of such particulars as he cannot by reasonable care and observation inform himself upon, for a man has no legal protection against the consequences of his own carelessness and negligence. If, however, he has been deceived in any other particulars, even unintentionally, by the buyer, he cannot be said to consent to the bargain. The consent which he gives is to the purchase of such property as has been described to him, and the consent therefore cannot relate to the property which is the subject of the sale, if it differs in material points from what has been described. Thus in the common case of a horse warranted sound, the consent is to buy a sound horse, and the buyer cannot be considered to have consented to buy an unsound horse. If therefore the horse is manifestly unsound, a party cannot be compelled to carry into effect his contract to purchase it. The case is the same with an estate said to be tithe free, which in reality is not so, or with any other property the description of which, as stated, varies materially from the truth. Where indeed the variance from the description is obvious, and the buyer has had an opportunity of inspecting the property and afterwards chooses to complete the purchase, the contract will not be invalid. The reason of this rule is manifest, for the legal presumption is that ordinary diligence has been used, where it might and ought to have been used, and there is therefore no ground for supposing an absence of the buyer's consent.

In cases where there is no fraud, and a possibility of variance from the description is contemplated in the conditions of sale, the sale may still be valid notwithstanding the existence of such variance, for in this case both parties knowingly take the chance of the variance being either favourable or adverse to them. As when for instance it is stated that an estate consists of so many acres, &c., be the same more or less, &c. If the conditions of sale contain a provision that compensation shall be made for such variances when they are ascertained, then the party in whose favour they turn out to be, will be bound to make such compensation. If, however, from the circumstances of the case it should appear that such compensation cannot be made, the sale cannot be enforced against the purchaser, forasmuch as the terms to which the parties consented are impossible, and there is therefore nothing to which the consent is applicable.

A court of equity will in some cases compel a buyer to complete his bargain, on the condition of the seller making him compensation in respect of those matters in which there is a variance, even although there is no provision to that effect in the conditions of sale. The principle on which this is done is, that parties ought to carry into effect what was substantially their intention. This power of the court therefore is not exercised where the variance is material, or where the attainment of the particular matter in which a variance exists really was the main object of the purchase. The common terms of exaggerated praise in which persons speak of the property that they have to sell, is not such misdescription as will make a sale void. In cases where property is agreed to be sold by one contract, in one lot, a buyer cannot be compelled to take some part of it without the rest.

3. No sale is valid if the subject matter of it is illegal or prohibited, or if an essential part of it is an illegal transaction or involves an illegal act. A sale of treasonable, blasphemous, or obscene publications is void, for the acts of treason, blasphemy, and obscenity are legally punishable. A sale of property known by the seller to be intended to be used for illegal purposes is void, such as drugs to be used for the adulteration of provisions, or a house to be occupied for the purposes of prostitution. Sales for the purpose of avoiding the forfeiture to the crown incident upon judgment after a conviction for felony, are void. Sales to an alien enemy are unlawful, although a power exists in the crown to grant licences legalising such sales. Offices of public trust, such as those which are connected with the administration of justice or government, either in the United Kingdom or in the dependencies upon it, cannot lawfully be made the subject of sale. The enactments affecting the sale of various articles are too numerous to be referred to here. It may, however, be laid down generally that where a thing is prohibited and made unlawful by statute, a contract for the sale of such thing is void, even although the statute does not enact that it shall be so, but only attaches a penalty to an infringement of its provisions. Sales of contraband articles are also void; and even in the case of a foreigner selling goods abroad, to be delivered in this country, the sale will be invalid, if he be cognisant of and aiding in an attempt to introduce them into this country in contravention of the revenue laws. A sale of property in the ordinary course of a party's trade is void if made on a Sunday, although the sale of the same article by another person whose ordinary dealings are not in such matters would be valid.

In case of a sale of lands, it is assumed that the seller has a good title to them, and that he will deliver over the title-deeds to the buyer. In failure of either of these particulars the sale cannot be enforced. The right to receive a good title is one which is conferred upon the buyer by the law, independently of any agreement between the parties.

By the statute 29 Charles II., c. 3, s. 4, certain forms were required in order to give effect to a sale of "lands, tenements, or hereditaments, or any interest in or concerning them." Such forms are no part of the sale, which consists in the consent of parties who are competent to consent, but the statute merely declares that such consent shall, in certain cases, have no legal effect, unless the prescribed forms are observed. If an agreement for sale has been made without the requisite formalities, and has been carried into effect in some material part, a court of equity will enforce the performance of the whole contract, on the ground that the informal contract, having been partly completed, is not a case within the statute. In all other cases of contracts as to interests in land, "the agreement, or some memorandum or note thereof, shall be in writing, and signed by the party to be charged therewith, or by some other person thereunto by him lawfully authorised." The agreement binds the party who signs it, although it is not signed by the other party. No established form is requisite, and it is not necessary that the agreement should be contained in one instrument: it may be collected from a series of letters, or a written offer followed by a written acceptance, or from documents referred to by a letter. The signature may be attached to any part of it. An agent may be appointed verbally, and the same person may act as agent for both parties to the sale. An auctioneer is such agent, and his writing down the name of the highest bidder in his book is a sufficient signature.

The law which relates to the construction of agreements for sale falls under the ordinary rules as to the construction of agreements generally. The same observation applies as to the remedies which parties possess for the enforcement of them. When the contract for the sale of an estate is completed, the estate is, in equity, considered to be sold, and the buyer is viewed as the owner of the estate, and the seller as only a trustee for the buyer, while the buyer is considered as a trustee of the purchase-money for the seller. If, therefore, a party has contracted for the sale of an estate of inheritance, and die before payment of the purchase-money, the money will be considered as part of his personal estate, and his executors will be entitled to it. On the other hand, if the party who has contracted to buy the estate die before it is conveyed to him, his heir or devisee will be entitled to the estate, and the executors must pay the purchase-money out of the personal estate of the buyer, if they have sufficient assets. It is a consequence of this equitable doctrine, that the buyer must, as a general rule, bear any loss which happens to the estate after the completion of the contract of sale. A person who has obtained such an equitable ownership may deal with the property in all respects as if it were his own; and such dealings, though not valid at law, are viewed as valid transactions in a court of equity.

With respect to sales of personal property, the common law required no formalities. The terms of sale might be agreed on either verbally or in writing; and they might be proved by any evidence legally applicable to the proof of other matters. Sales of goods made at one time, and not together exceeding in price 10*l.*, still remain on this footing. By the same statute (29 Chas. II., c. 3) which prescribed certain formalities in sales of land, it was enacted (s. 17) that "no contract for the sale of any goods, wares, and merchandise for the price of 10*l.* sterling and upwards shall be allowed to be good except the buyer shall accept part of the goods so sold and actually receive the same or give something in earnest to bind the bargain, or in part payment, or that some note or memorandum in writing of the said bargain be made and signed by the parties to be charged by such contract or their agents thereunto lawfully authorised." By the 9 Geo. IV., c. 14, s. 7, the enactments of this act are extended to all contracts for the sale of goods of the value of 10*l.* sterling and upwards, notwithstanding the goods may be intended to be delivered at some future time, or may not at the time of the contract be actually made or fit for delivery. The statutory requisites are thus four in number:—

1. Delivery and receipt of part of the goods.
2. Payment of earnest.
3. Payment of part of the price.
4. A signature of a memorandum of the bargain by the party or his agent. By the performance of any one of these requisites the parties to the sale are bound.

If the goods themselves are delivered to the buyer himself and accepted by him, of course no question can arise as to the completion of the bargain. Where, however, the delivery is not to him personally, many cases of nicety occur as to whether or not a delivery has taken place, so as absolutely to vest the property of the goods in the buyer. A delivery which would be sufficient, if not afterwards interfered with by the seller, to accomplish the requisite of the statute, is complete as soon as the goods have been delivered to a carrier for the purpose of being conveyed to the buyer, even although the carrier has not been selected by the buyer. But during the course of actual transit to the place indicated by the buyer to the seller as the place of destination, the goods are subject under certain circumstances to a right of the seller to detain them. This is called the right of stoppage in transitu, and the time and place when it ceases are often a question of great nicety. [STOPPAGE IN TRANSITU.] Where no delivery of part of the goods themselves has been made by actual removal, a constructive delivery may effect the same purpose: a delivery of the key of the warehouse where the goods lie; the receipt of rent for their warehouse-room by the seller; the endorsement and delivery of a bill of lading or a dock warrant; an order to a wharfinger to deliver, &c., amount to a delivery. In all such cases, however, it must be understood that the delivery is not complete if anything yet remains to be done to the goods on the part of the seller, such as their separation by weighing or measurement from a larger bulk. Again, the exercise of ownership over the goods by the buyer, with permission of the seller, is an act legally equivalent to delivery: such as marking the goods, tasting wine, and cutting off the pegs from the cask, &c. But in these cases it must distinctly appear that the act which is done is an act of ownership; if done with any other view, as for the purpose merely of identifying the property, it will of course afford no ground from which a delivery may be inferred. Where a sample is taken out of the whole bulk sold, a delivery of the sample operates as a part delivery.

2. The earnest-money paid must be retained. In a case where a shilling had been paid to bind a bargain, and was returned, it was held that this was not a compliance with the requisite of the statute.

3. The part payment need not necessarily be made in cash; a payment by acceptance of a bill, or by a promissory note, will, while the instruments remain undishonoured, have the same effect as by actual money.

4. The general observations which have been made as to a note or memorandum in writing relative to sales of land, will apply equally to one relative to sales of goods.

(Sugden, '*On the Law of Vendors and Purchasers*;' Ross's '*Treatise on the Law of Vendors and Purchasers of Personal Property.*')

SALEP, *Salap*, or *Saloop*, a nutritious article of diet, much valued in the East for its supposed general stimulant properties, but which is justly esteemed as bland and nutritious, and well suited to children and convalescents. Salep consists of the tubers of different species of *Orchideæ*, which have been known in medicine from very early times by the name *Orchis*. All the European saleps are far inferior to and considered only as indifferent substitutes for that brought by commerce from Africa. Salep is highly valued in India, and forms an article of commerce from Cabul and Cashmere to the north-western provinces of India, where it is sold, at the Hurdwar fair held in April, at a high price. This is very similar in form and appearance to Turkey salep, though the tubers are twice as large as the best procurable in London.

All the plants that yield salep have two tubers, charged with nutritious matter; while one is nourishing the flower-stem and seeds of the current year, by which it is robbed of its store, the other serves as a reservoir for the flower-stem of the succeeding year. This last alone is fit for use. Both are dug up together, but the solid one only is retained. It is dipped in warm water, after which the fine brown skin is easily removed by means of a coarse cloth or brush. The tubers, being thus peeled, are arranged on a tin plate, and placed within an oven heated as for baking bread; here they remain for seven or ten minutes, in which time they exchange their opaque and milky whiteness for a semi-transparent horn-like appearance and a yellowish colour, retaining their original bulk. Being then withdrawn from the oven, they are exposed during some days to dry and harden in the air; or, by the employment of a very gentle heat, they may be brought to the same state in the course of a few hours. All that is then required to adapt the salep for food is to boil it in water (or milk) to the required consistency. In Armenia, the tubers, while yet soft, are strung together on threads, and suspended in the sun to dry without artificial heat. The chemical composition of salep varies according to the period of growth when the tubers are taken up. Though salep is regarded as a variety of starch, there is very little pure starch present, the chief constituent being that form of gum termed *bassorine*. With cold water salep very slowly swells and forms a mucilage; but one part of salep-powder with forty-eight parts of water boiled or heated forms a thick mucilage, which has very peculiar qualities, inasmuch as with either calcined magnesia, bisulphate of quinnia, or biborate of soda, it thickens into a solid glue-like substance. The chief use of salep is as a mild and digestible article of food; and as the orchis abounds in our meadows, a large supply of nourishment might be obtained by digging up the tubers and drying them, as above stated, and as was recommended in the last century by Dr. Percival ('On the Preparation, Culture, and Use of the Orchis-root,' 1773).

Salep is composed chiefly of bassorine, some soluble gum, and a little starch; by some it is considered as containing the largest portion of nutritious matter in the smallest space. Its presence in small quantity in milk retards the tendency of that fluid to become sour. It is a harmless and useful ingredient in the preparation of bread, and is free from the objections to potato-starch, which is too often used by bakers in the place of wheaten flour.

SALERNITANA SCHOLA, will be found under this head in the BIOG. DIV.

SALHYDRAMIDE. [SALICYLIC GROUP.]

SALICIN. [SALICYLIC GROUP.]

SALICOR, the ash of the plant *Salicornia annua*. It is produced on the French coast of the Mediterranean, and is used in the manufacture of carbonate of soda, of which it contains about 15 per cent.

SALICYL. [SALICYLIC GROUP.]

SALICYLAMIDE. [SALICYLIC GROUP.]

SALICYLIC ACID. [SALICYLIC GROUP.]

SALICYLIC GROUP. A cluster of chemical substances, compounds or derivatives of the electro-negative radical *salicyl* ($C_{14}H_5O_4$). The members of this group—itself a subdivision of the benzoic series in Gerhardt's arrangement—are numerous; including the odoriferous oil of meadow-sweet and of winter-green, and the bitter principle of willow-bark.

Salicyl ($C_{14}H_5O_4$) itself has not yet been isolated. As it contains the elements of *phenyl* ($C_{12}H_5$) and *carbonic acid* (C_2O_4), and as, moreover, its compounds are not unfrequently converted into bodies identical with derivatives of phenyl, the salicylic group has sometimes been termed the *phenyl-carbonic group.*

Salicylide of benzoyl ($C_{14}H_5O_4, C_{14}H_5O_2$), *parasalicyl*, or *spirine*, is obtained by acting upon chloride of benzoyl with hydride of salicyl, or from the destructive distillation of salicylide of copper. It is insoluble in water, soluble in alcohol or ether, crystallises in prisms, melts at 260°, and sublimes at 356° Fahr., and is converted into picric acid on being boiled with nitric acid.

Hydride of salicyl ($C_{14}H_5O_4, H$); *salicylous acid*; *spirous acid*, or *essential oil of spiræa ulmaria.* Besides the method of obtaining this body from the flowers of meadow-sweet, as described under ESSENTIAL OILS, it may be produced by decomposing salicin under the influence of oxidising agents. According to Buchner, such an operation is simply an imitation of what occurs naturally in the *spiræa* flowers; the buds of this plant contain salicin, and have scarcely any smell; but, on expanding, freely expose their parts to the air, when oxidation of the salicin goes on, and hydride of salicyl results, giving odour to the flowers. The artificial oxidation of salicin is conveniently effected by bichromate of potash. To two parts of salicin, two of bichromate of potash, and sixteen of water, in a retort, are added three of oil of vitriol, previously diluted with eight parts of water. After a short time a gentle heat may be applied, when the oil passes over; twenty-five parts of salicin yielding six of the essence. The salicin for this process need not be pure; indeed, aqueous extract of willow-bark serves very well.

When quite pure, hydride of salicyl is a colourless oil, but from contact of air soon acquires a red hue. It has an agreeable aromatic odour, acrid taste, boiling point 360° Fahr., specific gravity 1·173, vapour density 4·276, and burns with a bright smoky flame. It is somewhat soluble in water, the solution giving a deep violet colour with persalts of iron. Hydride of salicyl is an acid body: it decomposes the alkaline carbonates with effervescence, and combines with bases generally to form neutral and acid *salicylides.* The potassium salts contain respectively $K, C_{14}H_5O_4 + 2$ Aq. and $K, C_{14}H_5O_4 + H, C_{14}H_5O_4$.

Chlorosalicylous acid ($C_{14}(H_4Cl)O_4, H$), *bromosalicylous acid* ($C_{14}(H_4Br)O_4, H$), *iodosalicylous acid*, and *hydride of nitrosalicyl* ($C_{14}(H_4NO_4)O_4, H$), are respectively produced by the action of chlorine, bromine, iodine, and nitric acid upon hydride of salicyl. They are crystalline compounds, and form crystalline salts with bases.

Salhydramide, *salicylimide*, or *hydride of azosalicyl* ($C_{42}H_{18}N_2O_6$) is the product of the action of ammonia upon hydride of salicyl:—

$$\underbrace{3C_{14}H_6O_4}_{\text{Hydride of salicyl.}} + \underbrace{2NH_3}_{\text{Ammonia.}} = \underbrace{C_{42}H_{18}N_2O_6}_{\text{Salhydramide.}} + \underbrace{6HO}_{\text{Water.}}$$

It crystallises in prisms, is insoluble in water, slightly soluble in cold alcohol, and more so in hot alcohol.

Chlorosamide ($C_{42}H_{15}Cl_3N_2O_6$), or the hydride of chlorazosalicyl, and *bromosamide* ($C_{42}H_{15}Br_3N_2O_6$) or the hydride of bromazosalicyl, are formed on acting with ammonia upon the chlorine and bromine derivatives of hydride of salicyl.

Thiosalicol ($C_{14}H_6O_2S_2$), or hydride of sulphosalicyl, is a pulverulent substance, formed on treating salhydramide with sulphuretted hydrogen.

Sulphurous derivatives of hydride of salicyl, and of the preceding compounds of salicyl, result from the action of sulphurous acid upon their alkaline salts, or of the alkaline bisulphites upon the compounds themselves.

Salicin ($C_{26}H_{18}O_{14}$) is a neutral bitter principle contained in the bark of the various species of willow and poplar (sallow, osier, aspen, &c.). It readily crystallises out from a concentrated decoction of the bark, after tannic acid and colouring matter have been removed by hydrated oxide of lead.

When pure, salicin occurs in white silky crystals, soluble in water or in alcohol, but insoluble in ether or oil of turpentine. It melts at 248° Fahr., loses water at 392° Fahr., and at a higher temperature decomposes. Concentrated sulphuric acid communicates a blood red colour to it; the liquid, neutralised with chalk, yields a deliquescent chestnut-brown powder, containing, according to Mulder, *sulphorufic acid.* Water decomposes the red body formed by sulphuric acid; heat, also, gives rise to the formation of a resinoid body, that has been called by one chemist *olivin*, by onother *rutilin*, while a third thinks it to be *saliretin.* Several chlorine derivatives of salicin exist.

Saligenin ($C_{14}H_8O_4$) and grape sugar result from the action of boiling dilute acids upon salicin:—

$$\underbrace{C_{26}H_{18}O_{14}}_{\text{Salicin.}} + 4HO = \underbrace{C_{14}H_8O_4}_{\text{Saligenin.}} + \underbrace{C_{12}H_{14}O_{14}}_{\text{Glucose.}}$$

Hence salicin is one of the glucosides. Saligenin crystallises in colourless crystals, very soluble in boiling water, alcohol, or ether. It is partially volatile; most oxidising agents convert it into hydride of salicyl, while chlorine gives rise to trichlorophenic acid.

Saliretin ($C_{14}H_6O_2$) is a product of the action of heat upon saligenin in closed vessels; it is also produced by prolonged ebullition of saligenin with dilute acids. It is a white or yellow-coloured resinoid body, insoluble in water or in ammonia, but soluble in alcohol, ether, or concentrated acetic acid.

Helicin (2 ($C_{26}H_{16}O_{14}$) + 3aq.) is obtained on digesting salicin in ten times its weight of nitric acid of specific gravity 1·160 for about a day: hydrogen is thus removed from the salicin, water being formed, and helicin deposited in acicular crystals. It is inodorous, of slightly bitter taste, very soluble in boiling water or alcohol, but almost insoluble in ether. Chlorine and bromine act upon, and give rise to derivatives of, helicin.

Helicoidin ($C_{52}H_{34}O_{28}$ + 3aq.) seems to be a combination of helicin and salicin ($C_{52}H_{34}O_{28} = C_{26}H_{16}O_{14} + C_{26}H_{18}O_{14}$). It is produced when the oxidation of salicin by nitric acid is incomplete, or when the specific gravity of the acid is less than that above indicated.

Populin ($C_{26}H_{17}(C_{14}H_5O_2)O_{14}$ + 4aq.), or salicin in which an equivalent of hydrogen is replaced by benzoyl, has already been described. [POPULIN.]

Coumarin, a fragrant principle of several plants, seems to be allied to the members of the salicylic group, inasmuch as it yields salicylate of potash when fused with the hydrate of that base. It is further described in a separate article. [COUMARIN.]

Salicylic acid (HO, $C_{14}H_5O_5$). In combination with methyl this acid exists naturally in oil of wintergreen. [ESSENTIAL OILS.] On boiling the oil for a few minutes with solution of potash, neutralising by hydrochloric acid, and allowing the mixture to cool gradually, salicylic acid crystallises out in acicular tufts. Salicylic acid may also be formed by projecting salicin, in small portions at a time, into hydrate of potash fused in a silver basin, the temperature not being allowed to rise higher than 750° Fahr. On dissolving the mass in water and adding hydrochloric acid, the salicylic acid is precipitated, and may be purified by recrystallisation from boiling water.

Salicylic acid fuses at 316° Fahr., and at a higher temperature sublimes unchanged. It is soluble in alcohol, ether, or oil of turpentine. A mixture of peroxide of manganese and sulphuric acid oxidises it to formic acid. By ebullition with nitric acid it is converted first into nitrosalicylic acid and, finally, into picric acid. Distilled with excess of lime it is split up into carbonic and phenic acids. Its solutions give an inky-blue precipitate with persalts of iron, the colour disappearing on the addition of hydrochloric acid.

Salicylic acid decomposes carbonates with effervescence, and forms *salicylates* that are, for the most part, monobasic and crystalline. The potash salt contains (KO, $C_{14}H_5O_5$, aq.); the *double salicylate of copper and potash* has the formula $KO, C_{14}\left\{\begin{matrix}H_4\\Cu\end{matrix}\right\}O_6 + 4aq.$: it crystallises in beautiful emerald green plates.

Salicylic ethers.—Although the oil of wintergreen appears to be a definite salicylate of methyl ($C_2H_3O, C_{14}H_5O_5$), it nevertheless plays the part of an acid, and from its source has been termed *Gaultheric acid*: it still admits of the replacement of an equivalent of hydrogen by a metal or a radical, *gaultherates* being formed; thus:—

Gaultherate of potash . . .	$KO, C_{14}H_4(C_2H_3)O_5$
Gaultherate of methyl . . .	$C_2H_3O, C_{14}H_4(C_2H_3)O_6$

But this gaultheric acid or hydrate of methyl-salicyl admits of the substitution of an acid radical for hydrogen, and thus are formed:—

Benzoate of methyl-salicyl . . .	$\left.\begin{matrix}C_{14}H_4(C_2H_3)O_6\\C_{14}H_5O_3\end{matrix}\right\}$
Cuminate of methyl-salicyl . . .	$\left.\begin{matrix}C_{14}H_4(C_2H_3)O_5\\C_{20}H_{11}O_3\end{matrix}\right\}$

Similarly the ethyl-gaultheric acid, or rather hydrate of ethyl-salicyl, and the amyl-gaultheric acid, or hydrate of amyl-salicyl, on being acted upon by the chloride of benzoyl yields:—

Benzoate of ethyl-salicyl . . .	$\left.\begin{matrix}C_{14}H_4(C_4H_5)O_6\\C_{14}H_5O_3\end{matrix}\right\}$
Benzoate of amyl-salicyl	$\left.\begin{matrix}C_{14}H_4(C_{10}H_{11})O_5\\C_{14}H_5O_3\end{matrix}\right\}$

Chlorine and bromine derivatives of salicylic acid result from the action of chlorine and bromine on salicylic acid. Their formulæ are:—

Chlorosalicylic acid	$C_{14}H_5ClO_6$
Bichlorosalicylic acid	$C_{14}H_4Cl_2O_6$
Bromosalicylic acid	$C_{14}H_5BrO_6$
Bibromosalicylic acid	$C_{14}H_4Br_2O_6$
Tribromosalicylic acid	$C_{14}H_3Br_3O_6$

Nitrosalicylic acid ($C_{14}H_4(NO_4)O_6$ + 2aq.), called also *indigotic acid* and *anilic acid*, has already been described [Anilic Acid]. *Binitrosalicylic acid*, or *nitropopulic acid*, contains $C_{14}H_4(NO_4)_2O_6$.

Anhydrous salicylic acid, or *salicylic anhydride* ($C_{14}H_5O_5$, $C_{14}H_5O_5$), is formed by the action of oxychloride of phosphorus on dry salicylate of soda. It is a gummy or oleaginous-looking body, soluble in alcohol. It is converted into ordinary salicylic acid by boiling with solution of potash.

Salicylide ($C_{28}H_8O_8$) is a white, amorphous, pulverulent substance, formed in the preparation of salicylic anhydride. It is insoluble in ether, and almost insoluble in alcohol.

Salicyluric acid ($HO,C_{18}H_8NO_7$) is found in the urine, after salicylic acid has been taken into the stomach. Boiled with hydrochloric acid it splits up into salicylic acid and Glycocoll.

Chloride of salicyl ($C_{14}H_5O_4$,Cl) is a fuming liquid, obtained on acting upon oil of meadowsweet by perchloride of phosphorus.

Salicylamide ($C_{14}H_7NO_4$) results from the action of a strong solution of ammonia on the oil of wintergreen. It is a volatile solid, of yellow colour, soluble in boiling water, alcohol, or ether. By the action of the chlorides of benzoyl or cumyl upon salicylamide the following compounds are generated:—

$$\text{Benzoyl-salicylamide} \;\ldots\ldots\; N\left\{\begin{matrix} C_{14}H_5O_4 \\ C_{14}H_5O_2 \\ H \end{matrix}\right.$$

$$\text{Cumyl-salicylamide} \;\ldots\ldots\; N\left\{\begin{matrix} C_{14}H_5O_4 \\ C_{20}H_{11}O_2 \\ H \end{matrix}\right.$$

Nitrosalicylamide $N\left\{\begin{matrix} C_{14}(H_4NO_4)O_4 \\ H \\ H \end{matrix}\right.$ is the product of the action of ammonia on nitrosalicylate of methyl.

SALICYLIMIDE. [Salicylic Group.]

SALICYLOUS ACID. [Salicylic Group.]

SALICYLURIC ACID. [Salicylic Group.]

SALIENT, a term applied to an angle which presents its point to the outside of the figure, as opposed to the re-entering or re-entrant, which is applied to an angle presenting its point to the inside of the figure. These terms are frequently used in fortification, and seldom in geometry.

SALIFIABLE BASE, a term applied to any substance capable of uniting with an acid to form a salt. [Salts.]

SALIGENIN. [Salicylic Group.]

SALII were twelve priests of Mars Gradivus, who formed an ecclesiastical collegium or corporation at Rome. They were chosen from the patricians, and established by Numa to take care of the twelve ancilia, or sacred shields of Mars. The original ancile was said to have been found in the palace of Numa, and was supposed to have fallen from heaven. To secure its preservation, Numa commanded the armourer Mamurius Veturius to make eleven other shields exactly like it; and the twelve were deposited in the temple of Mars on the Palatine hill, and committed to the care of the Salii. (Liv., i. 20; Dionys., ii. 70, 71; Cic., 'Rep.,' ii. 14; Ovid. 'Fast.,' iii. 387; Festus, s. v. 'Mam. Vet.')

On the calends of March, and on several successive days, the feast of Mars was celebrated by the Salii, on which occasion they carried the shields through the city dressed in their official garments, which consisted of an embroidered tunic with a brazen belt, the trabea, and the apex, or conical cap, with a sword by their side, and a spear or staff in their right hand. They at the same time performed a dance, and sung hymns or songs called Axamenta in honour of Mamurius Veturius, and all the celestial deities, with the exception of Venus, (Macrob., 'Sat.,' i. 12; Virg., 'Æn.,' viii. 286; Varro, 'De Ling. Lat.,' vii. 26, ed. Müller.) These songs were in later times scarcely understood even by the priests themselves. (Quint., i. 6. p. 54, Bipont.; Hor., 'Ep.,' ii. 1, 86.) At this festival the Salii were accustomed to partake of an entertainment in the temple of Mars, which was proverbial for its magnificence and excellence. (Suet., 'Claud.,' 33; Cic. 'ad Att.,' v. 9; Hor., 'Carm.,' i. 37.)

Another corporation of Salii, also consisting of twelve members chosen from the patricians, was established by Tullus Hostilius in fulfilment of a vow which he made in a war with the Sabines. These Salii were also called Collini or Agonenses, to distinguish them from the Salii established by Numa, who were surnamed Palatini. (Dionys. ii. 70, iii. 32; Varro, 'De Ling. Lat.,' vi. 14.)

SALIRETIN. [Salicylic Group.]

SALITHOL. [Phenylic Group.]

SALIVATION, or PTYALISM, is a superabundant secretion of saliva. This sometimes occurs as an idiopathic disease, originating without any evident cause. Dr. Christison ('Treatise on Poisons') has collected several such cases, in some of which the quantity of saliva discharged amounted to three or more pints daily. Irritation of the salivary glands, or accompanied with profuse secretion, is also an occasional attendant on common inflammations of the throat and mouth, and on those that accompany eruptive diseases, especially small-pox. But far more frequently salivation is the effect of medicines or poisons. Some preparations of gold, copper, antimony, and iodine, croton oil, digitalis, and even opium, are apt to produce it; and it is almost a constant effect of the long-continued or copious administration of mercury.

The quantity of mercury required to produce salivation varies greatly in different persons. In some, two or three grains of calomel are sufficient; but by other persons such large quantities may be taken with impunity, that they appear insusceptible of its action. No general rule, therefore, respecting the quantity of mercury that may be safely given to any one can be made; but in no case can there be safety without caution and careful watching of the effects produced by it.

Salivation from the use of mercury is distinguished from that which arises from other causes by its being preceded by a peculiar brassy taste in the mouth, fœtor of the breath, and tenderness, redness, and sponginess of the gums. These are soon followed by the increased flow of saliva, and if mercury be still taken, or if the quantity already taken was very large, they increase; the whole mouth, tongue, face, and throat become swollen and tender, and ulcers and sloughs quickly form on the mucous membrane. In extreme cases, the mouth and cheeks and throat become extensively gangrenous, the teeth fall out, the gums swell up as they do in scurvy, the jaws are affected with necrosis, and by the spreading of the disease to important parts it may prove fatal; or the patient may die exhausted by the profuse discharge of saliva, or by the peculiar nervous and other constitutional disturbances that often accompany the poisonous influence of mercury. [Mercury.]

The best treatment of mercurial salivation is exposure to cool pure air, a nutritious diet, and mild purgatives. Gargles of chlorinated soda or lime are useful in correcting the fœtor of the breath; and honey, or the *Mel Boracis*, may be applied to the smaller ulcers in the mouth. The permanganates of soda and potash may also be employed with advantage as gargles and lotions. The more extensive ulcerations and the gangrene can be treated only by maintaining the patient's strength by tonics and stimulants, and by the usual local applications to such diseases. The idiopathic kinds of salivation usually require only cool air and gently reducing measures.

SALIX, *Medical Properties of.* The barks of several species of willow have been long celebrated for their astringent and antifebrile qualities; but from the great difficulty of determining the species, it is not ascertained which kind is entitled to the preference. The *Salix Russelliana* (Bedford willow) appears to possess the greatest quantity of *tannin*; but the peculiar principle termed *salicin* seems to exist in the largest proportion in the *S. Helix*, or rose willow; while the *S. pentandra L.* (the bay-leaved willow), possesses, both in its bark and leaves, the largest amount of bitterness and resin, and a most balsamic odour. The barks of *S. alba*, *S. fragilis*, and *S. caprea* (or great round-leaved willow, which yields the broad-leaved willow bark), are also gathered, often indiscriminately. Whichever species is selected, the bark should be stripped in spring from branches not less than three years or more than six years old, and from trees growing in moist rather than swampy places. It should be carefully dried in the shade. The fresh bark has a faint odour somewhat resembling bitter almonds; the dried bark is devoid of odour. The taste is at first mucilaginous, afterwards bitter and astringent. The degree of astringency may be easily tested by adding to a decoction of the bark a solution of gelatine. Tincture of nut-galls does not affect it. According to the analysis of Pelletier and Caventou, the bark of *S. alba* contains a green fatty matter similar to that of cinchona, a yellow slightly bitter colouring matter, tannin, resinous extract, gum, wax, woody fibre, and an organic acid, which with magnesia forms a salt easily soluble in water and alcohol. Since these analyses, salicin has been found. [Salicylic Group; Salicin.]

Willow bark possesses astringent, tonic, and febrifuge qualities, which render it a valuable substitute for cinchona, and as it often suits the stomach better, it is well calculated for the treatment of agues among the poor. In debility of the stomach and relaxation of the mucous membranes, it is often very serviceable. In the latter cases, an infusion, made with cold water, of the powdered bark of *Salix pentandra*, is preferable; but any of the others may be made equal to it by the addition of bruised cinnamon bark. Like all astringent tonics, it is often useful as an anthelmintic.

Salicin has febrifuge properties, but they are much weaker than those of quinia; it must therefore be given in considerably larger doses. It may be given in substance or solution, and also in conjunction with many other salts, without undergoing decomposition or entering into combination. "In its passage through the system it undergoes oxidation, and is converted into hydruret of salicyle, which is found in the urine. Its presence is detected by a persalt of iron, which strikes an intense violet colour with urine containing it." (Pereira.) Of this property advantage might be taken in the treatment of some renal complains.

The barks of many species of willow contain a valuable dyeing principle. It is capable of dyeing drab with the help of a mordant only. For this purpose bitartrate of potass (cream of tartar) is best. If the bark be macerated in one vat, and the water then containing the colouring principle be drawn off into another vat, the mordant can then be added, and the stuff immersed in it. For the production of drab colour four materials are generally used, the shade resulting being often uncertain and varying in the same piece of cloth, in many spots being *foxy*, as it is technically termed.

SALSEPARIN. [SMILACIN.]

SALT. [SODA; SODIUM: MANURE.]

SALT CAKE. [SODIUM; *Sulphate of.*]

SALT OF SATURN, an old name for acetate of lead.

SALT OF SORREL. [OXALIC ACID. *Binoxalate of Potash.*]

SALT OF TARTAR. [POTASSIUM: *Carbonate of Potash.*]

SALT OF TIN. [TIN. *Protochloride of Tin.*]

SALT AND SALT TRADE. The chemical nature of common salt, as a chloride of sodium, is treated under SODIUM. The vast stores of rock-salt and salt-brine in Cheshire and Worcestershire, whence England obtains her supply, are described in the GEOG. DIV., under such headings as CHESHIRE, DROITWICH, NANTWICH, NORTHWICH, &c. A few additional details in this place are all that will be needed.

A rocky bed is the source of nearly all our inland salt; but as subterranean streams flow over this bed and become saturated with salt, the original form is changed. It is simply a question of manufacturing convenience, whether to raise the solid salt and purify it by dissolving, boiling, evaporating, &c.; or to raise the liquid brine and operate upon that. The salt-works adopt the latter course in most parts of England; but at Northwich they also operate upon a rocky kind of salt, which is transparent and colourless, and is loosened by blasting. There are other kinds of rock salt, much rougher and darker. On many parts of the coast salt is obtained from sea-water, at places called *salterns;* but as the salt would be too costly if evaporated by heat, the makers mostly rely on the slow process of evaporation by exposure to the open air. At Lymington both methods are combined.

In Cheshire the brine springs have been known and worked from very early times, but the bed of salt whence the brine is obtained was not known until about two hundred years ago. In the pits, the rock salt is loosened much in the same way as coal, by blasting and by the pick, and is brought to the surface to be dissolved in water. The brine springs in the valley of the Weaver mostly spring from a depth varying from 10 to 60 yards. The brine is pumped by steam power into large cisterns, where it is more completely saturated by an addition of rock salt. The brine then passes through wooden troughs to the evaporating pans, large flat open vessels with flues underneath. The evaporation, and the conversion into grains or crystals of salt vary according as *common* salt, *stoved* salt, *flakey* salt, *fishery* salt, &c., are to be produced; but in all, the crystals are allowed to form, and are then removed to the drying house. The blocks of common salt familiar in the shops are produced by transferring the crystals from the pan to wooden moulds, whence they are removed to be dried.

Nearly the whole of the salt exported is made in Cheshire, and is sent down the river Weaver, which communicates with the Mersey, to Liverpool. The sources of supply are said to be inexhaustible; and latterly the salt-manufacturers have so far extended their works, that the opening of new markets would be of the greatest advantage to them. The Staffordshire rock-salt is chiefly exported from Hull, and that of Worcestershire from the port of Gloucester.

A duty of 10*s.* per bushel was laid on salt in 1798, which in 1805 was increased to 15*s.* In 1823 this duty was reduced to 2*s.*; and on the 5th January, 1825, was wholly repealed. Salt used in the fisheries was always duty-free, and in 1821 the quantity so used was 2,406,602 bushels; and about 150,000 bushels, required by bleachers, was also exempt from the duty. A duty of only 5*s.*, which was afterwards reduced to 2*s.* 6*d.*, was charged on salt used for agricultural purposes. During the existence of the duty, the retail price was 4½*d.* per lb.; it is now about ¼*d.* Salt is now used more largely than hitherto by the poor, and is employed in manufactures and in agriculture to an extent which is only compatible with cheapness.

In 1852 an estimate was made that 300,000 tons of salt were used in the United Kingdom annually for domestic purposes, 200,000 tons for manure and manufactures, and 500,000 tons exported. In that year the prices varied from 2*s.* 6*d.* to 12*s.* per ton. The aggregate value of the whole was set down at 350,000*l.* In Cheshire only, in that year, there were 29 salt mines and 97 salt works belonging to 47 proprietors, employing 8000 persons, and an invested capital of 1,000,000*l.* In 1858 the total produce was believed to have risen from 1,000,000 tons to 1,400,000 tons annually, of which about one half is exported. If the above figures are correct, the domestic consumption must be far more than 16 lbs. per head, which was an estimate made several years ago. In 1858, the salt-manufacturers of Cheshire and Worcestershire memorialised the government, praying that means might be adopted for facilitating the consumption of British salt in India and China. A relaxation had been made in 1846, by which British salt was admitted under certain conditions into India; and the memorialists asked for still more favourable conditions. As for China, they suggested that, in any treaty between the two countries, a demand should be made for the admission of British salt, either free or under a small duty. The Cheshire manufacturers have, in fact, more salt than they know what to do with; and they are looking out for an extended market. At present, the two best customers are Calcutta and New Orleans, each of which takes about 80,000 tons a-year.

SALTPETRE. [POTASSIUM: *Nitrate of Potash.*]

SALTS. The term salt, originally restricted in its application to common salt, which it still means when used merely by itself, is now applied to a vast number of substances which have in many cases few properties in common.

Common salt is the principal of a class composed of a metal and such bodies as chlorine, iodine, bromine, and fluorine, and the radicals of the hydracids, and which are included by Berzelius in his class of *haloid-salts* (from ἅλς, sea-salt, and *εἶδος*, form), because in constitution they are analogous to sea-salt. The whole series of the metallic chlorides, iodides, bromides, and fluorides, such as chloride of sodium, iodide of potassium, and fluor-spar, are, as well as the cyanides, sulphocyanides, and ferrocyanides (though the three last are very differently constituted from the former), included by Berzelius in his list of haloid-salts.

It was for many years admitted as an unquestionable fact that common salt was a compound of muriatic acid and of soda; and hence it was very commonly called muriate of soda. But it has been shown by Davy, that the acid and alkali during their action on each other suffer mutual decomposition; and that while water is formed by the union of the hydrogen of the acid with the oxygen of the alkali, the chlorine of the former and the sodium of the latter unite to form chloride of sodium. It has since been proved that this occurs with all so-called *hydracids*, when they act upon metallic oxides: thus hydrochloric acid and soda give chloride of sodium and water, hydriodic acid and soda yield iodide of sodium and water, and hydrocyanic acid, cyanide of sodium and water, &c.

While then the hydracids, by the decomposition which they suffer, do not yield *hydro-salts* with the metallic oxides, yet hydro-salts may be formed by saturating these acids with the vegetable alkaloids; for example, hydrochloric and hydriodic acids yield respectively hydrochlorate and hydriodate of quinine, when made to act upon this base. With ammonia hydrochloric acid forms the salt called sal-ammoniac; but these salts are analogous to the chlorides, chloride of ammonium being formed by the conversion of the ammonia into ammonium, by the transference of the hydrogen of the hydrochloric acid to the ammonia, which is theoretically supposed to consist of one equivalent of nitrogen and four equivalents of hydrogen, instead of one equivalent of nitrogen and three equivalents of hydrogen, which exist in ammonia.

The *oxy-salts* form another numerous and important class of compounds: these are formed when an oxacid is made to combine with an oxidised base; as, for example, when sulphuric acid unites with soda, the result being sulphate of soda. The sulphates of potash, lime, magnesia, &c., are similarly constituted; but a question has arisen whether these salts are not also analogous to the chlorides, in containing a metal rather than an oxide; thus, instead of supposing that sulphuric acid, composed of one equivalent of sulphur and three equivalents of oxygen, is combined with soda, formed of one equivalent each of sodium and oxygen, it has been, and with much plausibility, supposed that the oxygen is transferred to the sulphuric acid, forming a compound which has never yet been isolated, consisting of one equivalent of sulphur and four equivalents of oxygen, and that this is combined with sodium. Professor Daniell proposed the name of *oxysulphion* of sodium for such compound, while Professor Graham denominates it a *sulphat-oxide* composed of *sulphat-oxygen* and sodium.

Another class of bodies has been described by Berzelius as coming within the description of salts; namely, the sulphur-salts. Electro-positive sulphides, termed *sulphur-bases*, are usually the protosulphides of electro-positive metals, and therefore correspond to the alkaline bases of those metals; and the electro-negative sulphides, *sulphur-acids*, are the sulphides of the electro-negative metals, and are proportional in composition to the acids which the same metals form with oxygen. Thus sulpharsenious acid (AsS_3) and sulpharsenic acid (AsS_5) combine respectively with sulphide of potassium (KS) to form the sulpharsenite and sulpharseniate of potassium. These salts obviously correspond with the arsenite and arseniate of potassium. Hence, if the sulphur of a sulphur-salt were replaced by an equivalent quantity of oxygen, an oxy-salt would result.

In general properties the various classes of salts, and indeed the individuals of the same class, differ as widely as possible; some are crystallisable, others uncrystallisable; they are colourless, and of various colours; sapid and insipid; soluble and insoluble in water, alcohol, and other menstrua; volatile and fixed in the fire; decomposable or undecomposable by the same reagent.

Salts have been conveniently, though not quite correctly, divided into alkaline, earthy, and metallic salts; for, strictly speaking, most of the two former belong to the latter, and to these classes must be added the ammoniacal salts and the salts of the vegetable alkaloids. Again, salts constituted of the same elements may contain one or other in excess; thus soda and various other bases combine with three different portions of carbonic acid. The first is the *neutral* carbonate, containing one equivalent each of acid and of base; the second contains one-half more carbonic acid, and is called the sesqui-carbonate; and the third contains twice as much carbonic acid as the first, and is the bi-carbonate.

Super-salts are such as contain an excess of chlorine or of acids, and sub-salts such as contain excess of base. Dr. Thomson has proposed—and it is very conveniently adopted in practice—to describe the degree of excess of acid in the super-salt by Latin terms, and that of the excess of base by Greek: thus while a compound of two equivalents of chlorine and one of a base, or of an acid and base, is called a bi-chloride or bi-sulphate, as the case may be, a compound containing one equivalent of chlorine or acid to two of base, is termed a *di-chloride*, &c. [CHEMICAL NOMENCLATURE: *Nomenclature of Salts.*]

SAMARITAN CHARACTERS, are the old Hebrew characters, which were disused by the Jews during the Babylonish captivity, but retained by the Samaritans, from which circumstance, and especially from their being used in the extant copies of the Samaritan Pentateuch, they have obtained their present name. They are nearly the same as the Phœnician characters. [ALPHABET; HEBREW.]

SAMENESS or IDENTITY. This term is generally applied to what is called personal identity, or the sameness of a living and intellectual being, as man. There are some remarks on this subject by Bishop Butler in his 'Dissertation of Personal Identity.'

The sameness of objects which are external to a man consists in the perception of a variety of circumstances as to these external objects and at different times, from which arises an opinion of sameness in a certain sense. A man sees a tree growing in a certain place, and he may have remembered it for many years. But in the mean time the tree may have increased a hundred-fold in bulk, and therefore its substance is not the same as that of the tree which he first saw there; and besides this, there may not be a single particle of matter the same in the tree at two remote times of his observation. The tree then is by the supposition not the same in a strict sense; but for all practical purpose it is called and is the same. A man can no more believe that all the change that the tree has undergone belongs to some other tree, than he can believe that the growth of his own body belongs to another being than himself.

When sameness is applied to a living and intellectual being, it includes both the matter of the body and something else. A man can have no doubt that his body is not entirely the same in youth, in middle age, and in old age. He can view his body as he does any thing external, and he has a belief that it undergoes changes, and is therefore not the same in the strict sense. But yet he considers himself the same person; person here including something besides the body, whether that something be a property of an organised body or something else. Locke, as quoted by Butler, says, "that the consciousness of our own existence, in youth and in old age, or in any two successive moments, is not the same individual action, that is, not the same consciousness, but different successive consciousnesses." Butler's answer to this vague talk is sufficient. But more may be said. How is consciousness of our personal identity, or if this form of words be objected to as a way of begging the question, how is the thing called "consciousness of our existence" at any two successive moments shown to be "not the same consciousness, but different successive consciousnesses?" What are successive moments in a man's consciousness of his own existence? It is more consistent with that consciousness which we have, to say that the consciousness of our personal identity is one and the same always; and if it is allowed that there is in man a belief that he is at different times the same being, in some sense which he cannot otherwise explain than that he feels that he is, it follows that this consciousness of personal identity is one indivisible thing, that it is as continuous as the personal identity itself which it presupposes. Nor is it any objection that a man's faculties may be temporarily impaired by illness, and he may lose the exercise of his reason and recover it; or an accident may befall him, which for a time renders his bodily and mental powers inactive, though he may finally recover both. On his recovery he does not doubt that he is the same person that he was before his illness or accident, and therefore his consciousness is one. The division of consciousness by successive times, corresponding to certain external signs, and the making that supposed succession a ground of objection to personal identity, is to confound things that are unlike, and to apply a measure to both that does not fit one of the things.

"Every person," says Butler, "is conscious that he is now the same person or self he was, as far back as his remembrance reaches." This cannot be disputed. It is a bare fact that this consciousness does exist in us. We have not this consciousness from the time of our birth up to manhood and old age: it does not go further back in its particular manifestations than our remembrance does; yet we doubt not that we, the man, were once that particular child of our parents rather than any other child of these parents or of any other parents. But this belief is derived from evidence: our consciousness in its particular manifestations does not extend farther back than our remembrance. Yet remembrance does not make personal identity, as Butler remarks: "Consciousness of personal identity presupposes, and therefore cannot constitute personal identity, any more than knowledge, in any other case, can constitute truth, which it presupposes."

The remembrance of particular things is a very different thing from the consciousness of personal identity. When this consciousness begins, when it ends, how its activity is suspended, we know not: but we know that it is a law of our nature that, in the ordinary state of a man's bodily and intellectual faculties, he has a perception, whatever it may be and however it may arise, whenever he reviews certain acts of his own or events in his life, that he the perceiver, and no other person, is the agent or is the person affected by these events. The remembrance then merely makes the consciousness of personal identity active; and this consciousness of personal identity is not constituted of the remembrance of different acts or events, but is as permanent and uninterrupted as the animal life itself, which nobody supposes to consist of successive lives, but to be one life. And it should be observed that the question of personal identity only arises upon the suggestion of the memory. Every man all through his life feels that he is in some sense or in some way, which he expresses by that term "is." And he is never without this present consciousness of existence. There is therefore an uninterrupted consciousness, which, as already observed, is one, and not divisible by a measure of time. The remembrance of any particular act of a man's own or of any event in his own life, is a present act, and the consciousness of such present act of memory accompanies the act of memory as it does any other present act; and as the act of memory is retrospective, so is the consciousness of that act of memory retrospective, but only incidentally, according to the nature of the act. The memory merely directs the conscious agent to an act of the kind called passed, and to a passed act of such a kind that the consciousness of sameness in the agent is inseparable from the notion of the act that is remembered.

SAMIELI is the Turkish name of a wind which the Arabs call *samoom*, or *simoom*, which in Egypt is called *khamsin*, and in Senegambia and Guinea *harmattan*. It occurs in most countries which are situated at no great distance from sandy deserts, and it blows always from that quarter in which the desert is situated. Thus, in Senegambia and Guinea it blows from the north-east; in the Delta of the Nile from the south-south-west and south-west; on the eastern shores of the Gulf of Suez from the north-east; in Syria from the south-east; at Mecca from the east; at Bagdad from the west; at Basra from the north-west; and at Surat from the north. These winds are extremely hot, and a considerable quantity of fine sand is generally suspended in the air, which has been collected by the winds in rushing over the desert. They affect the human body very powerfully, producing great feebleness, and sometimes even death. They usually consist of a quick succession of hot and cold puffs of wind; and the difference of the temperature between these puffs, which is stated to amount to more than twenty degrees of Fahrenheit's thermometer, is probably one of the reasons of their effect on animal bodies being so great. It is also thought that the hot puffs bring a pestilential air, as a putrid and sulphureous smell is perceived when they blow. Formerly it was asserted that the hurtful effects of the wind could be avoided by a person throwing himself on the ground with the mouth downward; but modern writers say that the Arabs disapprove of such a proceeding, and perhaps justly, if it is true that the hot air is heavier than the atmosphere. To diminish the effects of the wind, the Arabs cover their faces with the *kefieh*, a handkerchief which they wear on their heads.

SAMPHIRE, a herb used in some parts of the country as a salad and pickle. The true samphire is the *Crithmum maritimum*, a plant belonging to the natural order *Umbelliferæ*. It is a very succulent plant, with pale green leaves, and flowers arranged in umbels. It grows on rocks by the sea-side. The species of *Salicornia* [SALICORNIA, in NAT. HIST. DIV.] are often called samphire, and are used in the same manner; but they are inferior to the *Crithmum* as an article of diet.

SANCTIFICATION, a term in theology, denoting the highest Christian attainment; the state of those who are perfectly pure and holy, having lost the inclination to vice, and are wholly devoted to virtue and godliness. It is understood to be produced by the special operation of the Holy Ghost, and to ensue upon justification.

SANCTUARY, a consecrated place which gave protection to a criminal taking refuge there. The word also signifies the privilege of sanctuary, which was granted by the king for the protection of the life of an offender. Under the dominion of the Normans there appear early to have existed two kinds of sanctuary, one general, which belonged to every church, and another peculiar, which commenced and had its force in a grant by charter from the king. This peculiar sanctuary could not be claimed by prescription only; and it was also necessary that it should be supported by usage within legal memory, and allowance before the justices in eyre. These two kinds differed from each other with respect to some of their privileges. The general sanctuary afforded a refuge to those only who had been guilty of capital felonies. On reaching it, the felon was bound to declare that he had committed felony, and came to save his life. [ABJURATION OF THE REALM.] A peculiar sanctuary might, if such privilege was granted by the charter, afford a place of refuge even for those who had committed high or petty treason; and a party escaping thither might, if he chose, remain undisturbed for life. He still, however, had the option to take the oath of abjuration and quit the realm. Sanctuary seems in neither case to have been allowed as a protection to those who escaped from the sheriff after being delivered to him for the purpose of execution. During the latter part of the reign of Henry VIII., at the time when the religious houses were dissolved, several statutes were passed (26 Henry VIII. c. 13; 27 Henry VIII. c. 19; 32 Henry VIII. c. 12), which regulated, limited, and partially abolished the privilege of sanctuary, both as regarded the number and classes of criminals entitled to it, and also the places possessing the privilege. Finally, by 21 James I. c. 28, s. 7, it was enacted that no sanctuary or privilege of sanctuary should thereafter be admitted or allowed in any case [ABJURATION OF THE REALM; ASYLUM.]

(Reeves's *History of the English Law;* Comyn's *Dijest*, tit. 'Abjuration;' 4 Bl., *Com.*)

SAND. The fine angular materials derived from the disintegration of rocks, and deposited according to the gravity of the various particles under the action of running water, are technically known by the generic term "*sands.*" They are, for the purposes of classification, subdivided into river sand, sea sand, and pit sand; volcanic, calcareous, argillaceous, or silicious sand; red, yellow, or white sand; according to their manner of occurrence, their qualities, or their colour. In the arts they are used for many purposes, but as their applications in the manufacture of mortar, of plastic building materials, and of glass, are, perhaps, of the greatest practical importance, attention will be principally called to these applications; but before doing so it may be of interest to observe that the sea-sands on some parts of the shores of the Atlantic are largely used in agriculture, on account of the large quantity of calcareous and nitrogenous matters they contain. This application of sand, of the description known locally by the name of "tangue," prevails in the departments of the Calvados, Manche, Côtes du Nord, &c., in France, to a very great extent, and it is found to be very beneficial.

For mortar making, sands may be selected according to the properties of the lime in connection with which they are employed, as under some circumstances they play a very important part in the chemistry of the hardening of the mortars. As was said under MORTAR, the value of that class of materials depends upon the rapidity and the energy with which the double silicate of lime and alumina is formed; and it therefore follows that the sands which contain the various ingredients in a state susceptible of entering into combination with the lime, are those which are of the greatest value. The sands derived from the destruction of the purely silicious rocks are for the most part totally inert for the purposes under consideration, because the silica they contain is in a permanent crystalline form; but the sands derived from the destruction of gneiss, grauwacké, felspathic granites, and other rocks, in which the silicious acid does not exist in a stable compound, are easily acted upon by pure caustic lime. Thus it is found that in the north of Spain, and in the granitic district of the north of France, the decomposition of the felspathic granites of those districts has produced a sand in which the silicate of lime of the felspar exists in a state able to combine with the pure hydrate of lime, there obtained by slaking the caustic lime derived from the more pure crystalline limestones. The volcanic sands, known technically by the names of *pozzuolanos* and *trass*, act even more energetically than the sands from the felspathic rocks; and when mixed with the pure hydrate of lime in proper proportions, they even communicate to it properties nearly similar to those of natural cements. On the other hand, sands containing plastic clay in its natural state are positively injurious; not only because the clay does not exist in them in a state able to form any stable compound with the lime, but also because it prevents the latter from performing one of its most useful functions in a mortar; namely, that of presenting a nucleus around which crystallisation could take place in the lime itself. At the present day it is believed that with the energetic cements a sharp, angular, crystalline sand, one whose chemical properties would be totally inert, is the best adapted for mortar making; with hydraulic limes the sands ought to possess the faculty of slowly forming new compounds with the hydrates of lime; and with rich limes, especially if they are required to be used in sea-water, sands exercising an energetic action on the hydrates must exclusively be used.

These remarks point to a rough practical subclassification of sands, into the classes of the *inert*, *slightly energetic*, and *decidedly energetic* sands; and Vicat, who was the first to call attention to this description of action, states that when sands are treated by acids and by lime-water they may easily be distinguished from one another. Thus the inert sands resist the action of acids, and are totally without action upon even boiling limewater. The slightly energetic sands yield in a trifling degree to the acids, and take up a small proportion of lime from the lime-water. The decidedly energetic sands are powerfully affected by acids, and they take up a large proportion of the lime presented to them in solution. Care must, however, be taken in the experiments on the nature of this class of materials to allow for the action of the acids upon the lime present in the sand; for all purposes connected with the formation of the insoluble silicate of lime and alumina by the reciprocal actions of the caustic lime and the sand, the calcareous matters of the latter will remain practically inert.

When considered with reference to their sources of supply, it may generally speaking be regarded that sea sands are purer and better fitted for mortar making than any other; provided always that the efflorescence of the muriate of soda they contain should not be likely to affect injuriously the character of the work. This would be the case with all internal decorations; and sea sand must therefore be carefully excluded from all ornamental structures. River sand is also very likely to contain the muriate of soda when obtained from the tidal portions of a stream, and in addition to this inconvenience there is almost a certainty that the river sand will contain a large proportion of nitrogenous elements, which would in a building give rise to the formation and efflorescence of the nitrate of lime, which in its turn would be fatal to any coloured decorations or paintings exposed to its effects. Pit sand is in fact the most generally fitted for building purposes; but care must be taken with it to secure that it should be free from argillaceous ingredients, and only that sand should be used whose grains are sharp and angular. The specific gravity of a sand is a *primâ facie* evidence of its goodness.

In brick and tile making, and in some processes of the higher ceramic arts, sand is occasionally used when the clay is, to use the workman's phrase, "too rich;" that is to say, when it is exposed to run together in the kiln in an irregular manner, in consequence of an excess in the proportion of alumina the clay may contain. A clay is considered, in fact, to be *rich* when the proportions of silica and alumina are respectively 60 and 40 per cent.; it is considered to be *poor* when those proportions are 80 and 20 per cent.; and according to the usage intended to be made of the clay a greater or less proportion of pure silicious sand must be added to the richer varieties. See Brogniart, 'Traité des Arts Céramiques.'

The very pure and perfectly white silicious sands which are found in Norfolk and in Alum Bay, Isle of Wight, used formerly to be raised in large quantities for glass making. The supply has been nearly exhausted; and latterly some of the best sands for this important branch of manufacture have been imported, in ballast, from Australia; rich ferruginous sands for steel making are also imported from New Zealand.

It may be desirable to add, that the fine sands charged with organic matters to be found in the embouchures of rivers, or in some bays on the sea-shore, are technically known by the name of silt, and that they are very rarely of any commercial value. Pit sands, or large deposits of sand in the interior, are occasionally found to be so charged with water as to remain constantly in motion, and are then called *running sands*. Under these conditions they form one of the most dangerous class of foundations, for if an escape should be found for the waters they may contain, the sands would in all probability be removed by them, and the foundations would be exposed to lateral displacement. The precautions to be taken in such cases are, if possible, to intercept the supply of water to the sand; if that cannot be effected, to keep it constantly charged; and, under either of those conditions, to isolate the immediate surface of the foundations in such a manner as to allow any movements which may be produced to take place vertically. Dry sand has, in its dry state, been often used in foundations instead of concrete; and if it be prevented from spreading laterally, that material is practically incompressible. It is also used for tamping round the charges of mines.

SAND; SANDPAPER. Many varieties of sand are used for manufacturing purposes. Stone-masons often use the scrapings of granite roads to aid the action of their stone-saws. Engineers frequently employ grindstone dust. River-sand and pit-sand are generally sharper or more angular than sea-sand; this difference leads to the selection of each for certain purposes. Kent sand is largely used at Sheffield, being fine and sharp; it is found an economical substitute for polishing powder for steel goods. *Sand-paper* consists of sand sprinkled over and cemented upon sheets of paper; it differs from emery-paper [EMERY] and glass-paper rather in the kind of substance used than in the nature of the action.

SAND VOLTAIC BATTERY. A form of battery sometimes used in connection with the Electric TELEGRAPH, consisting of a number of pairs of copper and zinc, with the cells filled with sand, which is kept moist by means of dilute sulphuric acid. This battery will remain active for a considerable time, and its activity can be renewed at pleasure merely by wetting the sand.

SANDAL-WOOD, RED, or Red Saunders Wood of Commerce. [PTEROCARPUS, in NAT. HIST. DIV.]

SANDARAC is a secretion from the *Callitris quadrivalvis*, a tree of enormous size, native of Marocco, and there called Arar. It exudes spontaneously from the bark, and concretes on the surface. It occurs in small, irregular, but rather elongated, seldom perfectly round tears, or in masses run together, of a light yellow colour, sometimes verging to brownish, of a dull hue externally, generally covered with powder, but when this is removed, semitransparent. It breaks easily with a conchoidal fracture and vitreous lustre. The powder is white, and forms the substance called *pounce*. By chewing, it forms a fine powder, which does not agglutinate, and has a faint balsamic taste. At ordinary temperatures it is without odour, but by the application of heat it easily melts and diffuses a strong though not unpleasant odour, resembling that of juniper or mastic. It is easily ignited. It is soluble to the extent of four-fifths in cold alcohol; and the insoluble residuum is easily soluble in ether, or, slowly and with difficulty, in boiling turpentine. The portion insoluble in alcohol is termed *Sandaracin*.

Sandarac is used for the preparation of varnishes, also occasionally for incense or pastiles, plasters, and ointments. The powder is rubbed on parchment to render it fit to be written on. Sandarac is sometimes used to adulterate mastic; and on the other hand, a resin obtained from the *Juniperus communis*, and another from *J. Oxycedrus*, are employed as a substitute for the genuine sandarac. In Sweden, lumps of resin which are found under ants' nests below the juniper bushes are called sandarac. The resin of the *Pinus dammara* is called French sandarac in commerce. Sandarac is incorrectly called a gum; it partakes more of the nature of a resin.

SANDEMANIANS. [SANDEMAN, ROBERT, in BIOG. DIV.]

SANDIVER. [GLASS MANUFACTURE.]

SANGUINARINE. ($C_{[illegible]}H_{[illegible]}NO_{[illegible]}$?) An alkaloid, found in the *Sanguinaria Canadensis*, but only partially investigated. It is a yellow insipid powder, insoluble in water, but very soluble in alcohol. It neutralises acids perfectly, forming red salts, which are soluble in water and very bitter.

SANHEDRIM, or SANHEDRIN (סַנְהֶדְרִין), the great council of the Jews, which consisted of seventy-one or seventy-two members, and decided the most important causes, both ecclesiastical and civil. The name is a corruption by the Talmudists of the Greek συνέδριον (*a council*). The rabbis attempt to find the origin of the Sanhedrim in the seventy elders who were appointed by Moses to assist him in his judicial duties (Numb. xi. 16); but this council was evidently temporary, and we hear nothing of it in the subsequent history of the Jews. (MOSES, in BIOG. DIV.; Michaelis 'On the Laws of Moses,' art. 50.) The exact time of the institution of the Sanhedrim is unknown; but there is no reason to suppose that it was earlier than the time of the Maccabees. There can however be little doubt that the Sanhedrim was an *imitation* of the seventy elders of Moses. The first mention of the Sanhedrim is in the time of Hyrcanus II., when Herod was tried before it. (Joseph., 'Antiq.,' xiv. 9, s. 3, 4.)

The Sanhedrim had a president (רֹאשׁ or נָשִׂיא), who was generally the high-priest, a vice-president (בֵית אַבִי דִין) who sat on the right of the president, and, according to some, a second vice-president (חָכָם). who sat on his left. The other members were:—1, *Chief Priests*, who are often mentioned in the New Testament and in Josephus, and who were partly ex-high-priests and partly the heads of the twenty-four classes of priests. 2. *Elders*; that is, the princes of tribes and heads of families. 3. *Scribes*, or men of learning. All chief priests were members of the Sanhedrim, but of elders and scribes only so many were admitted into it as were required to fill up vacancies. (Matt. xxvi. 57, 59; xxvii. 3, 12, 20, 41; Mark viii. 31; xi. 27; xiv. 43, 53; xv. 1; Acts iv. 5; v. 21, 27.) The Talmudists say that the tribunal had its secretaries and apparitors. Both Pharisees and Sadducees were found in it. (Acts v. 17, 21, 34; xxiii. 6.)

The Sanhedrim met at Jerusalem, and, according to the Talmudists, in a chamber within the precincts of the Temple, called *Gazith*, in which also their archives were kept; but, according to Josephus ('Bell. Jud.,' v. 4, 2; vi. 6, 3), in a room on the east side of Mount Zion, not far from the Temple. In cases of emergency, as in the trial of Christ, they met in the high-priest's house.

The causes brought before this tribunal were either appeals from the inferior courts, or matters which were thought of sufficient importance to come before them in the first instance: for example, the question whether a person was a false prophet (Luke xiii. 33), and matters which effected the whole state, a whole tribe, or the high-priest. The accused was brought before the tribunal, and witnesses were required to appear to support the charge. Either capital or minor punishments might be inflicted by the Sanhedrim; but under the Roman government its power was so far restricted that a capital sentence required the confirmation of the Roman governor, who was also charged with its execution. The stoning of Stephen was not done in accordance with the sentence of the Sanhedrim, but in a riot; and the execution of James and others by the high-priest Ananias (A.D. 64) took place in the absence of the Roman procurator, and is admitted by the Jews themselves to have been an illegal act.

Besides the Sanhedrim at Jerusalem, there were inferior courts in each town of Judæa, consisting of twenty-three members, to which the same name is sometimes applied. From these courts an appeal could be made to the Sanhedrim.

(Jahn, *Archäol. Bibl.*, th. ii., b. ii., § 186; Calmet's *Dictionary*; Lightfoot's *Works*; Winer's *Bibl. Realwörterbuch*, 'Synedrium.')

SANJAK, a word primarily signifying a standard, is also applied to a military division, the subdivision of an eyalet, into which the whole Turkish empire is divided: in this sense, it signifies, as much as is congregated under one standard. The commander of such a division is styled Sanjak, Sanjak Bey, or simply Bey, and the supreme general of all the Sanjaks of a province is styled the Beglerbey (commander of commanders). The word is found under the forms Sangiac and Sandschack, the French and German modes of rendering the Turkish word.

SANKHYA. [SANSKRIT LANGUAGE AND LITERATURE.]

SANSKRIT LANGUAGE AND LITERATURE. *Language.*—The Sanskrit is a branch of the Indo-Germanic family of languages. Of all these languages it is that which approaches nearest to the primitive type; and by the originality, purity, and abundance of its forms, is peculiarly calculated to throw light on the obscure laws of the formation of language. Being also possessed of a rich literature, and the whole of its materials having been fully treated of by native grammarians, it was no sooner introduced to the learned of Europe than it gave rise to a new philological science, that of comparative grammar, and led to the conclusion that the ancient Persian, the Armenian, the Greek, and the Latin, formed but one language with the German, the Lettic, the Slavonian, and even the Celtic, each of these languages affording the most extraordinary illustrations of the others.

The Sanskrit was introduced into India when the Brahminical race obtained possession of the country (A. W. von Schlegel, 'De l'Origine des Hindous,' in the 'Trans. Roy. Soc. Literature,' ii., 2, 405, &c.; Chr. Lassen, 'Indische Alterthumskunde,' i. 515, 531, ff.; M. Müller, 'History of Ancient Sanskrit Literature,' 1859, p. 12); and having driven out the languages of the aborigines of India, which are now only spoken in the Southern Deccan, as the Telugu, Tamul, Canarese, and, others, and by some detached tribes, chiefly in the Vindhya mountains, for example, the Gonds and Khonds (Lassen, l. l. i., 366, ff.; M. Müller, 'On the Classification of the Turanian Languages,' p. 169, ff.; R. Caldwell, 'Compar. Grammar of the Dravidian Languages,' 1856, p. 8, ff.), has spread over the extensive tract of country between the Himalayas, the Indus, and the Kistna. Within these limits it has had a history of its own, and has passed through various changes. It appears in its most ancient form in the Vedas, about the 15th century before Christ, and in that state is very nearly related to the Zend, the ancient language of Persia, and contains many forms and words which have become obsolete. The classical Sanskrit, on the contrary, having once become fixed, has, for about 3000 years, partly as a living language and partly as a learned one, retained the same structure, with the mere exception of difference in style, and a few archaisms, which only occur in the most ancient works.

Prakrit dialects.—Out of the Sanskrit, however, even in comparatively early times, dialects arose, which gradually became still farther removed from the original and from each other; and from these dialects those of the languages now spoken in India are derived, which do not belong to the aboriginal languages mentioned above. There is a law, however, which pervades the whole of those *Prâkritas*, that is, derivative languages, as they are called by the Indian grammarians, in contradistinction to the *Sanskrita*, or that language which is regularly and grammatically constructed (A. Weber, 'Vorlesungen über indische Literaturgeschichte,' 1852, p. 168); and it is worthy of remark, that this law is precisely the same as that according to which the Romance language, the Italian, the Spanish, and the French, have grown out of the Latin. There is the same softening, the same assimilation, and the same exclusion of the harsher sounds, the same weakening of the forms, the same substitution of particles for cases, and the same periphrastic conjugations.

The oldest of these dialects, and that which deviates least from the Sanskrit, is the *Pâli*, which has become the sacred language of the southern branch of the Buddhists, who, when they abrogated the institution of castes, required a language which, at least for works not strictly scientific, should not be exclusively understood by the privileged classes. Having originally been carried by the Buddhists from Northern India to Ceylon, the Pali has continued to exist in that island, as well as in Burmah, Siam, and Kamboja, and possesses a copious literature. (Burnouf and Lassen, 'Essai sur le Pali,' Paris, 1826; Clough, 'Pali Grammar,' Colombo, 1824; 'Journ. Ceylon Branch R. As. Soc.,' 1847, No. 3, p. 189, ff.; Pallegoix, 'Gramm. Linguæ Thai,' Bangkok, 1850, p. 181, ff.) Different from the Pali is the *Gâthâ*, or ballad dialect, which appears only in the poetical portion of the Buddhist literature of Nepal ('Journ. As. Soc. of Bengal,' xxiii. p. 604; 'Lalita Vistara,' ed. by Rajendralal Mittra, Calc. 1853, ff.) The language which, in a peculiar sense, is called Prakrit, properly *Mahârâshtrî* (for its local origin is to be sought in the country of the Mahrattas), differs little from the Pali; it is used by the Jains. The *Mâgadhî* and the *Saurasenî*, the former originally spoken in Behar, and the latter on the banks of the Jumna, are only a little farther removed from the Sanskrit. (Lassen, 'Institutiones Linguæ Pracriticæ,' Bonn, 1838; J. Muir, 'Original Sanskrit Texts,' vol. ii., p. 138, ff., where the different opinions on the origin of the Prakrits are set forth and examined.) In addition to these there are numerous more modern dialects, among which we shall only distinguish the Vrajabhâshâ (Brij Bhakha), on account of the excellence of its poetical literature, and as being the parent of the Hindustani.

The formation of the Prakrita languages out of the Sanskrit flowed naturally from the character of the parent tongue, and this tendency is manifested even in the earliest shape of the Sanskrit. This appears, to take a single instance, in the substitution of the *ch* and *j* (the Italian *ci* and *gi*) for the original *k* and *g* (just as the Italian *gielo* is formed from *gelu*). In like manner, it was perfectly consistent with the character of the classical Sanskrit to adopt the verbal forms of the Prakrit, and to retain them together with the legitimate and settled forms, which is a proof that the two languages must have co-existed for a long period.

The Pali appears as a perfectly-formed language in the Buddhist works carried to Ceylon, which we cannot fix at a later date than the 4th century before Christ (Lassen, 'Ind. Alt.,' ii. 489; Muir, l. l. p. 65-107); and the Mâgadhi dialect has been found distinctly recorded, in the middle of the 3rd century before Christ, in the inscriptions of King Asoka, which were first deciphered by the late Mr. J. Prinsep ('Jour. Asiat. Soc. Beng.,' 1837, pp. 566, 794, 963), whose translations were subsequently revised by Prof. H. H. Wilson ('Journ. R. Asiat. Soc.,' for 1849, vol. xii., p. 153-251, and vol. xvi., p. 357, ff.); and a portion of them were lastly examined by M. E. Burnouf ('Le Lotus de la bonne Loi,' Paris, 1852, p. 652-781), whose researches on the whole question may be considered as conclusive (Lassen, 'Ind. Alt.' ii. p. 215-229). A Prakrit language likewise appears on the coins of the

Greek kings found in Caubul, and near the Indus, which have been deciphered by Prinsep, Lassen, Wilson, and E. Thomas. (J. Prinsep, 'Essays on Ind. Antiquities,' Lond., 1858, 2 vols.) Many of the names also which have been transmitted to us by the Greeks are Prakrit; that of the Deccan, for instance, in the Periplus of the Erythræan Sea, Δαχιναβάδης, does not correspond to the Sanskrit *dakshinâpatha*, but strictly to the Prakrit *dakkhinabadha*. Hence it follows, that in the last five centuries B.C. the Prakrit must have become completely the language of the people; and indeed the dramas which were written about this time show the relation of the two languages in the most distinct manner, the men speaking Sanskrit, and the women and inferior characters Prakrit; which is likewise a proof that the Sanskrit was actually a living tongue, and was used in conversation by all educated people. This is proved by many other circumstances; and it would be a great mistake to view the Sanskrit as having become from this time merely a learned language. On the contrary, it was in vogue at the court of Cashmere as late as the 12th century A.D. (Lassen, l. l., iii., p. 1082, ff.), and probably in the small independent courts of Malwa even in the 14th and 15th centuries. It is consistent with all that we know, that the language should be in a different condition in the different provinces of India, The Mohammedan conquest, however, gave the final blow to it, and it is now used only in learned disputations in the colleges of the Brahmins.

Literature.—The Sanskrit literature begins with the Vedas, and is founded entirely upon them. [VEDAS.] The rest of the literature may be divided into the poetical and the scientific. The poetical literature may be referred to two distinct periods, one of which is chiefly distinguished by the composition of the great epic poems, and the other may be characterised as the period of artificial poetry. In the former, the interest is a national one, and arises from the subject; in the latter, it depends upon the form.

Epic Poetry.—We possess the epic poetry only in its most perfect state, and consequently its origin is involved in obscurity, and must be looked for among the rhapsodists, whom the 'Râmâyana' presents to us pretty much in the same character as that in which they appear among the later princes of India. The materials of the epic consisted primarily of the genealogies of the princely families whom the rhapsodists served, and next, of certain prominent events in the family history, which were at first sung separately, but afterwards incorporated in the genealogy itself. It is possible therefore that there may have been as many epic poems as there were princely races. In the lapse of time, however, all these poems have been lost except two, which are indebted for their preservation partly to their poetical merit, and still more to the interest of the subject: these are the 'Râmâyana' and the 'Mahâbhârata.' But even these have undergone many important alterations since they came from the hands of the authors; in fact, they have been entirely remodelled in accordance with the interests of the priesthood, by the addition of those parts in which Râma and Krishna, originally no more than mortal heroes, appear as incarnations of Vishnu; these additions, however, have been so loosely attached, that they might easily be separated without detriment to the whole. In the 'Mahâbhârata,' the object has been kept in view of including in one collection the whole cycle of tradition; and as the epic poems were intended for the instruction and amusement of the warrior caste, not only was everything added which could increase their reverence for the Brahmins, but there are whole books, of considerable length, in which their systems of cosmogony, philosophy, and law are explained in a popular manner.

The Râmâyana.—The subject of the 'Râmâyana' is the descent of Vishnu, for the purpose of averting the threatened destruction of the whole world by the prince of the demons, Râvana. Râma, the son of Dasaratha, king of Oude, was brought up by wise Brahmins, especially Visvâmitra; while yet very young he overcame the demons in several battles, and by his superhuman strength obtained the hand of the beautiful Sitâ. He was about to be appointed successor of his aged father, and to be his partner on the throne, when the plan was frustrated by a court intrigue, and he was compelled to wander abroad as an exile. With Sitâ and his brother Lakshmana, who also participated in the divine nature of Vishnu, he dwelt in the inhospitable wilds of the Deccan, in the forest of Dandaka, at the sources of the Godavery. This course of events was necessary in order to bring him and Râvana together, for here Râma made himself terrible to the demons, and having mutilated, among others, Sûrpanakhâ, the sister of Râvana, the demon prince, partly out of revenge for this outrage, and partly inflamed by violent love for Sitâ, carried her off, and brought her in safety to his residence at Lankâ (Ceylon). Râma and Lakshmana, unacquainted with the abode of Râvana, wandered about in the peninsula in search of Sitâ. The ape-king Sugriva, who had been dethroned by his own brother Bâli, was restored to his kingdom by Râma, and from a feeling of gratitude sends out a host of apes for the purpose of finding the abode of Sitâ. The ape Hanumân at length discovers it, passes across the strait, seeks out and speaks with Sitâ, sets fire to Lankâ, and conveys the intelligence to Râma, who proceeds with the whole army of apes to the southern point of the peninsula, when an enormous bridge is formed by throwing mountains into the sea. As the army is about to march upon the island, Râma is encountered by Vibhishana, Râvana's brother, and a Titanian conflict commences, the description of which is one of the most admired parts of the poem: but the demons are at length subdued; Râvana falls by the hand of Râma; and Sitâ is recovered, and having been found pure, as well by the ordeal of the gods as by the word of Brahma himself, she is again united to Râma, who, returning to Ayodhyâ, receives from the hand of his brother Bharata the dominion to which he is entitled.

These are the contents of the first six books, and here the poem terminates. But there is a seventh book, which is obviously a later addition, and consists of matters which are entirely independent of the former narrative: Sitâ is again separated from Râma, and bears two sons, Kusa and Lava, to Vâlmiki. After her innocence has been again established, she is carried away by the goddess Earth. Kusa and Lava have learned the poem from Vâlmiki, its mythological author, and recite it at a great sacrificial festival. whereupon Râma acknowledges them as his sons. This is obviously an etymological myth derived from the Sanskrit name of the rhapsodists, *kusîlava*. This agrees with the present introduction to the first book, in which the origin of the poem is told in the same way, and both parts must therefore be regarded as additions made by the last editor. That the 'Râmâyana' has undergone many other alterations, may easily be shown. It contains, in some parts, many things which point to very ancient times, and customs introduced at a later period are not even alluded to; as, for instance, the burning of widows, which was practised in the age of Alexander. In other parts circumstances are referred to which bring us as far down as the 2nd century A.D., the names of comparatively recent nations being mentioned: for instance, the Huns.

The time of the composition of the poem cannot therefore be ascertained with any further degree of accuracy; and it is still a controverted question whether the Mahâbhârata or the Râmâyana, in the form in which they have been handed down to us, has the better claim to antiquity. It is more easy to determine what historical fact forms the foundation of it. This is evidently the introduction of the Brahminical worship and civilisation into the peninsula, the wild aborigines of which, as being the opponents of Brahminism, are made to appear in the character of demons. The apes must represent another and a less hostile race, whom the Brahmins made use of in order to overcome the ruder tribes. This fact is indicated by another circumstance in the poem: the guide of Râma is the hermit Agastya, to whom tradition ascribes the conversion and cultivation of the Deccan, and who even now shines, according to a sublime symbol, as the radiant Canopus of the South.

The 'Râmâyana,' since the last recasting of the poem, has undergone several revisions, four of which are known to exist (Weber, 'Verzeichniss der Berliner Sanskrit-Handschriften,' 1853, p. 119), which differ from one another less in substance than in style and arrangement. That which contains the oldest and the best text is confirmed by commentaries; a critical edition of it to the end of the second book, accompanied by an elegant Latin translation (as far as ii. c. 20), by A. W. von Schlegel, appeared at Bonn, 1829, 3 vols. The same recension is represented also by the Oxford manuscript ('Catal. Cod. MSS. Sanscriticorum,' 1860, vol. i., p. 6). An edition, based on a different text, was commenced by Carey and Marshman (Serampore, 1806-10, 4 vols. 4to); it goes as far as iii. c. 63, and contains also an English translation. The whole Râmâyana, according to the Bengali or amplified recension, was edited, with an Italian translation, by G. Gorresio (Paris, 1843-58, 10 vols.); there is also a French translation of the same by M. H. Fauche (Paris, 1854, ff., 9 vols.)

Mahâbhârata.—For the second of the two great epic poems, see the article MAHÂBHÂRATA.

Laws and Jurisprudence.—Besides the book of Manu, which has obtained the highest reputation among the 'Dharmasâstras,' or law-codes [MANU], there were many similar books, which were likewise referred to sacred mythological personages, as Vishnu, Vrihaspati, Nârada, and others. The principal sources from which they draw are the 'Sâmayâchârikasûtras,' a class of works belonging to the last period of the old Vaidic literature, in which the laws of caste, the rules of discipline, the occupations of kings, householders, &c., and the adminstration of justice, are accurately detailed. (M. Müller, 'History of Anc. Sanskrit Lit.,' p. 134.) There was a considerable number of these works, according to the different Vedas or Vaidic schools to which each professed to belong, the names by which they went being either those of their authors or of the families in which they were first current. These names were retained by the compilers of the Dharmasâstras; and the law-book of Âpastamba, for example, is distinctly traceable to the Sâmayâchârikasûtras which bear the same name. The subjects of which the Dharmasâstras treat are these three: *Âchâra*, comprising domestic and civil observances and all matters relating to caste; *Vyavahâra*, of the duties of kings and the administration of justice; and *Prâyaschitta*, of the civil consequences of caste-defilement, or other sinful actions, and of the way how to avoid those consequences by purification and penance. This threefold division is strictly adhered to in the law-code of *Yâjnavalkya* (edited by Prof. Stenzler, in Sanskrit and German, Berlin, 1849), the first after Manu in point of time and authority. In the other law-codes (eighteen of which were printed, together with that of Yâjnavalkya, at Calcutta, 1845, ff.), prominence is given to one or other of those three divisions. In the laws of Vishnu, for example, the judicial portion is very meagre, whereas the first and third are more fully treated than either in Manu or Yâjnavalkya. The laws of Daksha and Parâsara contain nothing about civil law at all, but so much the more about purification, penance, &c. These minor *Smritis*, as they are also called (*Smriti* means immemorial usage), are for the most part of small extent, and touch upon civil law only incidentally; they are, moreover, although received in common by all the schools, no longer final authorities, even where they do treat of law. For that purpose recourse must be had to the Commentaries and Digests. "Some of the former are merely explanatory of the text, but others are regarded as final authorities; and these latter, together with the Digests, form the immediate groundwork for the opinions of lawyers in the respective schools where the doctrines they uphold may prevail. Many of the Commentaries on the Smritis —such, for instance, as those on Manu's institutes—are not considered to be final authorities, any more than the Smritis themselves; but others again which, by the introduction of quotations from other writers, and by interpreting and enlarging on the meaning of the author, partake so far of the nature of general Digests, are referred to for the final decision of questions. The 'Mitâksharâ' (printed at Calc., 1812) is a remarkable instance of this; since, though professedly only a commentary on the Smriti of Yâjnavalkya, it is consulted as a final authority over the whole of India, with the exception of Bengal alone." (Morley, 'The Administration of Justice in Brit. India,' 1858, p. 213.) In the Bombay presidency are Nîlakantha's 'Mayûkha,' and in the Deccan the 'Smritichandrika' by Devandabhatta, of equal authority with the 'Mitâksharâ;' whereas in Bengal the latter has been entirely superseded by the 'Dâya Bhâga' (on the laws of inheritance) by Jîmûta Vâhana. For the modern law literature in Sanskrit, which is very extensive, consult Wilson's preface to Macnaghten's 'Principles of Hindu and Mohammedan Law,' London, 1860; Morley, 'The Administration of Justice in Brit. India,' p. 213–36; Sir A. Steele, 'Summary of the Law and Custom of Hindu Castes,' Bombay, 1827, p. 1–29; Borradaile's Introduction to his translation of the 'Vyavahâra Mayûkha,' Surat, 1827.

Purânas.—The Purânas, if we regard the form, must be classed with the ancient epic. They are voluminous collections of legends and traditions, written to elucidate the origin and history of some particular holy place or a certain sect, and to be read to the people for their instruction at the great festivals. They all begin with a cosmogony, to which they add the genealogy of the gods and the development of the periods of the world, as well as unconnected historical traditions, so as to form a fabulous chronology; and thus they come down to the history of the sacred place to which they are especially dedicated; they then conclude with the miracles, and so forth, which have been performed there. As they were intended to be read publicly, they are of course used as vehicles for conveying such instruction as the people might be presumed to require. They contain, therefore, not only recommendations to devotion and faith, and copious representations of the religious usages and customs, but also systems of the sciences which were known to the natives of India, as astronomy, mensuration, and jurisprudence, which are different in each Purâna, according as the priesthood of a temple belonged to this or that sect, or to this or that school of philosophy, astronomy, or law. In their present form, the Purânas are decidedly very late compositions, but the elements out of which they have been constructed belong to very different periods. They themselves refer to still older sources, and all the circumstances combined lead to the conclusion that there must have been another set of Purânas, which are now lost, and of which the present are an altered form or an imitation. Their great similarity, as well in their general structure as in particular parts, shows that they must have been formed upon one type, and that one very ancient, and that the differences which they present arise from the difference of object, according as they emanated from this or that place, or this or that sect. The older authorities actually give definitions of the Purânas which do not apply to them as they exist at present, and which presume an older form. It may even be asserted that entire portions of them must originally have belonged to the Vedas. In their present shape, none of the Purânas can be referred to an earlier date than the 9th century A.D., and the greater part of them are much later, and closely connected with the formation of the more recent sects. Though they are metrical compositions, they have no pretensions to poetic merit, if we except the 'Bhâgavatapurâna,' which was probably written by Vopadeva. They are arranged according to a certain canon, and are eighteen in number, under the titles of Brahma, Padma, Brahmânda, Agni, Vishnu, Garuda, Brahmavaivarta, Siva, Linga, Nâradîya, Skanda, Mârkandeya, Bhavishya, Matsya, Varâha, Kûrma, Vâmana, and Bhâgavata. Besides these, there are said to be eighteen *Upapurânas*, or secondary Purânas, only a few of which, however, are known. There are many others, not included in this canon, which are called *Sthalapurânas*, or local Purânas, and are of little importance. Several of these have been described by Prof. Wilson, in the 'Catalogue of the Mackenzie Collection' (Calc., 1828). The Purânas have been chiefly made known to us by the analyses of Wilson, in the 'Asiatic Journals' of Calcutta and London; by his translation of the 'Vishnupurâna,' London, 1840, 4to; and by Burnouf's edition of the 'Bhâgavata,' 3 vols., Paris, 1840-47, fol., as far as B. ix. Two complete editions have appeared in India, one at Calcutta, 1830, and the other at Bombay, 1839, both with the scholia of Sridharaswâmin. An edition of the 'Mârkandeyapurâna' was commenced at Calcutta in 1855.

Artificial Poetry.—Sanskrit poetry received a new character, and one essentially different from that which we have been just considering, in consequence of the revolution which took place in Sanskrit literature about the first century before Christ. Instead of the popular and national character which appears in the two great epic poems, it now assumed an artificial form, and became the poetry of courts and princes. How this was effected cannot be historically shown, for the various steps of the transition are lost, and the new poetry appears at once in its perfect state. It is, however, quite obvious that the two great epic poems had long been completed and were in universal repute. The new poetry is poor in invention, and drew its materials from the former. Its whole merit consists in what may be called style. Even the epic versification is for the most part neglected, and lyric metres are substituted for it. This is not merely a difference in external form, but it is connected most intimately with the mode in which things are viewed by the Indians, who, being devoted to contemplation, delight to work up their poetical materials not so much into a continuous action, as into a series of single situations. Each of these situations is exhibited in a single stanza or strophe, which forms an independent whole, and is not connected with the others either grammatically or metrically. This peculiarity is as obvious in the epic as in the lyric and dramatic poetry.

The *new Epic poetry* begins with Kâlidâsa, to whom two works of this class have been ascribed, 'Kumârasambhava' and 'Raghuvansa.' [CÂLIDÂSA, in BIOG. DIV.] They are written in a style worthy of imitation, and their whole character shows that they are older than the others, from whose superfluities these early works are free. The materials belong to the mythic cycle of the 'Râmâyana.' The disposition to describe rather than to narrate is exhibited as well in single passages as in the whole. Whenever an opportunity occurs, long descriptions are introduced, such as pictures of natural objects, to which the old epic poetry was also inclined, but more sparingly, and only incidentally: here, however, they encumber the whole progress of the action. This is much more the case in the two following poems, in which the descriptions appear to the poet to be so important that he seems to have undertaken the works only for the purpose of introducing them. These works are the 'Kirâtârjunîya,' or "the battle of Arjuna with the Kirâta," by Bhâravi, and 'Sisupâlabadha,' or "the death of Sisupâla," by Mâgha, both founded on episodes of the 'Mahâbhârata.' They are classical compositions, and elaborated with the utmost nicety; but the art of the poet degenerates into a mere play upon words. There are verses which may be read forwards and backwards, and upwards and downwards; others in which only one and the same consonant is used (as "Sis. 19, 114, 'dâdado duddaduddâdî dâdâdo dûdadîdadoh duddâdan dadade dudde dadâdadadado' dada," which indeed is not very clear, but still has a meaning), or two consonants or more are used. These poems were printed at Calcutta, 1814, 1815, and again 1848, with the commentary of Mallinâtha. The 'Bhattikâvya,' written in the 5th or 6th century, in Vallabhî, the chief town of Guzerat, narrates the history of Râma, but only for the purpose of elucidating the more rare grammatical forms, every canto being written in a certain tense, &c. (Published at Calcutta, 1828, with two grammatical commentaries.) The 'Nalodaya,' falsely ascribed to Kâlidâsa, gives the history of Nala out of the Mahâbhârata, but only to show the skill of the poet in an incessant play of words and rhymes. (Edited by F. Benary, with the commentary of Prajnakâra, a Latin translation and notes, Berlin, 1830; and by W. Yates, with a metrical translation, grammatical analysis, &c., Calc., 1844.) The most artificial of all these poems is the 'Râghavapândavîya' of Kavirâja. (Published at Calc., 1854, with a commentary by Premachandra Tarkavagîsa.) It is written with such a purposed double meaning, that the same words give us the histories of Râma and also of the sons of Pandu, which is only possible in consequence of most of the Sanskrit proper names having also a perfect appellative meaning, so that in the one history the proper names must be dropped, and in the other the appellative meanings. We shall mention in the last place the 'Naishadîya' of Srîharsha, king of Cashmere in the 12th century. It treats of the marriage of Nala, and nothing else, in twenty-two long cantos, written throughout in a very artificial manner, which however makes it a great favourite among the Indians. The descriptions in this poem exceed in length and number all reasonable bounds, and there can hardly be said to be any action at all. It was printed at Calcutta in two volumes, the first with the commentary of Premachandra, 1836, and the second with that of Nârâyana, 1855.

Lyric poetry, in the proper sense of the term, did not exist among the natives of India at this period, for even here their fondness for description has taken the place of everything else, and, instead of lyric poetry, we have the epigrammatic, didactic, and descriptive. Even their amatory poetry appears to be not so much the expression and effusion of feeling as a studied and laboured display of situations. An agreeable work of this description, the 'Amarûsatakam,' consists of 100 single small poems, each of them being nothing more than a stanza which represents an amatory scene, and which we should call an epigram. (Published at Calcutta, 1808.) To this class belongs also the 'Sringâratilaka,' which has been improperly ascribed to Kâlidâsa. To these must be added the first book of the 'Centuries' of

Bhartrihari, while the two other books contain didactic poetry. The work has been ascribed to the brother of King Vikramâditya, who lived in the 1st century, B.C.; and we have the high authority of Prof. Lassen ('Ind. Alt.,' ii. 803, 1161), for the probability of this assertion being correct. (First edited at Serampore, with the 'Hitopadesa,' 1804; and at Berlin, 1833, by Bohlen.) Among the poems properly called descriptive, by far the best is the 'Meghadûta,' certainly a genuine work of Kâlidâsa, which in a style of the utmost elegance and simplicity, describes the course of a cloud over a part of India, the residence of the god of riches and of the wife of a demigod who had been banished to earth [CÂLIDÂSA, in BIOG. DIV.]: the poem is put in the mouth of the demigod himself. The value of this poem as a work of art lies chiefly in this, that every single external phenomenon receives a spiritual meaning, and all nature seems to be endowed with life. It is very different in the later poems of this class, which are properly only rhetorical centos and collections of all the current expressions and comparisons of previous poets. A work of this kind on the seasons—a subject indeed which is frequently introduced in the epic poems, the 'Ritusanhâra'—has been improperly ascribed to Kâlidâsa. (Printed at Calcutta in 1792, and at Leipzig in 1839.) A similar one on amatory common-places, 'Chaurapanchasikâ' (in Bohlen's 'Bhartriharis'), is bombastic and spiritless. This branch of literature must have been very rich, and many of the older works have undoubtedly been lost. Most of those that are extant, including the 'Meghadûta,' 'Ritusambâra, 'Gîtagovinda,' 'Nalodaya,' 'Bhartrihari,' 'Amarûsataka,' are contained in Hœberlin's 'Sanskrit Anthology,' Calc., 1847.

The Drama.—According to the tradition of the Hindus, the Indian drama had its origin in very ancient times, the rules concerning it having been communicated by Brahmâ himself to the hermit Bharata (which means the supporter, bard, actor). Though we are unable to trace it historically, as we know it only in its perfected form, still we may perhaps not be far wrong if we fix about the end of the 4th or the beginning of the 3rd century B.C. as the most probable time when it received its first development. An examination of the technical terms employed in the Hindu drama favours the supposition that, in its first stage, it consisted in dances, accompanied by gestures and songs, in which some historical event was celebrated; that then the persons themselves who were the subjects of those songs were represented by the singers; and that, lastly, the regular dialogue took the place of the dancing and singing. (Lassen, 'Ind. Alt.,' ii. 502-5; Weber, 'Ind. Lit.,' 184, ff.)

Such performances are still retained in their original form at the festivals of Rama and Krishna. The characters of the pieces come forward one after another, and sing a song accompanied with gesture. It is obvious that a considerable time must have elapsed before so simple a beginning could have grown into a regular dialogue and a complicated action, in which mythological and domestic, and even historical, materials are interwoven into the representation. But the Indian drama, even in its highest state, is still in a low condition. Among the Greeks and the moderns individual action and the collision of moral powers form the moving forces of the drama; but that of India is rather a series of events and situations which are exhibited in succession to the spectator. The distinction between tragedy and comedy is unknown, and the Indian drama most nearly resembles the modern opera. The Indian dramatists have not yet arrived at the discrimination of character; the heroes and heroines resemble one another more or less in all their dramas; and the species rather than the individual is everywhere represented. There are also standing characters, such as the *vita*, who is the *gracioso* of the Spanish stage, and the *vidûshaka*, who is the clown of the old English. This latter personage is always the necessary attendant of the principal hero, whom he parodies, and whose ideal wishes he contrasts with his own practical views, and these contrasts are often very strongly coloured. The strict rules of the Greek drama are unknown to that of India, and even in many external particulars it is comparatively unfettered,—as, for instance, in the number of acts, of which there may be as many as ten. In the form there are two peculiarities which especially require notice: first, the interchange of dialects in the dialogue, which is in general skilfully and delicately managed, and gives us a high idea of the social cultivation of the Indians in those remote times (it has already been observed that the heroes speak Sanskrit, but that the women and inferior characters speak various dialects of Prakrit); and, second, the interchange of prose and verse. The dialogue is entirely in prose, but is interspersed with verses in the lyric metres, always of the descriptive character before mentioned, which sometimes exhibit a feeling or a situation, and sometimes describe something which cannot be actually represented on the stage, as the rapid travelling of a vehicle. As to the scenic representation, our information is limited. It may be inferred from their rhetorical books that great care was bestowed on the declamation and the costume, but the stage-management and the decorations appear to have been very rude. Still the dramatic literature of India is beyond all doubt much richer than we are yet aware of. The names of about 60 pieces are known to us, of which 13 have been edited, and we are indebted to Professor Wilson for longer or shorter notices of 20 others. ('Theatre of the Hindus,' 2nd edit., Lond., 1835.) Fortunately, the pieces which have been edited are sufficient to enable us to take a rapid view of all the eras and divisions of this branch of their literature.

The classic age of the Indian drama may be divided into three periods: the first includes the time before Kâlidâsa, of which only one piece remains, 'Mrichhakati,' 'The Toy-Cart,' by King Sûdraka (who probably lived about the end of the 1st century A.D.). It is easy to discover that this piece belongs to the early period of art: the poet has to contend with materials which he does not well know how to handle. There is a certain clumsiness in the management of the acts and scenes, and the excess of descriptive poetry is fatiguing, a whole act, for instance, being occupied with the description of a storm. In other respects it is strikingly original, and contains few of the common-places which occur in the other poets; the different dialects of the Prakrit also are more closely amalgamated than in the other pieces. To Europeans this drama is particularly valuable, as giving a representation of Indian manners which cannot be found in any other work. Though it is the only remaining piece of this period, many others must have existed before Kâlidâsa; for the general theory of the dramatic art was already perfected, which is obvious from his frequent allusions to it.

The second period begins with Kâlidâsa (about the middle of the 2nd century A.D.), under whom the Indian drama reached its highest degree of perfection. We have two pieces by him, 'Sakuntalâ' and 'Vikramorvasi' [CÂLIDÂSA, in BIOG. DIV.], of which the last has been denied to be his; but, to judge from the style and spirit, it must certainly be ascribed to him. Kâlidâsa is indeed the most perfect of the Indian dramatists, for in his pieces we have the utmost elegance of style, without anything over-laboured or artificial; the development of his plot is natural and well considered; and there is always a correct relation of parts. As to his poetical merit, Europeans have been enabled to form a judgment from the graceful translation of his 'Sakuntalâ,' by Prof. M. Williams (Hertford, 1855).

The third period begins with Bhavabhûti, at the commencement of the 8th century, whose era is established by a passage in the 'Chronicle of Cashmere' (iv. 144). Dramatic poetry had now undergone a great change, the historical progress of which we are unable to describe for want of the necessary evidence. Bhavabhûti was a learned poet, who constructed his works entirely according to the dramatic theory of previous writers. He has accordingly a very high reputation in India, but he has all the faults consequent on the direction thus given to his genius. With all his poetic talent, he is deficient in true dramatic spirit; his results are laboured, and there is always a display of art and a want of nature. Description is with him always in excess, and the diction of single passages is not only too artificial, but also pompous, and to Europeans therefore not without difficulty. There are three pieces of his; one in which a domestic subject is treated, the loves of Mâlati and Mâdhava, and two others taken from the cycle of traditions of the Râmâyana, 'Mâhâviracharitra,' and 'Uttararâmacharitra.' The last is most free from the excessive elaboration of style.

As specimens of dramas of intrigue in the Indian style, 'Ratnâvali' and 'Mâlavikâgnimitra' are worthy of notice. The first was written in the 12th century by some poet at the court of Sriharsha, king of Cashmere; the other was long prior to Bhavabhûti, probably by Kâlidâsa himself. The plan of these pieces is not unskilful, and the language is easy and graceful; the subject itself warning the poet to avoid a highly ornamental style. Another kind of interest belongs to the 'Mudrârâkshasa' of Visâkhadatta; the exact time to which this drama belongs is unknown, but it is certainly after Bhavabhûti; the matter is historical, namely, the history of Chandragupta, the Sandrocottus of the Greeks. In the deficiency of historical information, even such a tradition is important, and the piece also throws much light on the politics of the Indian courts. As a drama it is not of much value; it is mostly written in prose. The 'Prabodhachandrodaya' ("the rising of the moon of reason") is of a character quite peculiar: it is an allegorical play, written by Krishnamisra in the 11th century, in which purely abstract ideas, as virtues, passions, and crimes, are personified and act, and by means of whom the Vedânta philosophy at last celebrates her triumph. Setting aside the strangeness of such a work of imagination, it must be admitted that the author has performed his task with great skill.

It was much later before the peculiar species of drama made its appearance which is called *prahasana* (*comedy*, or rather *farce*). The pieces are short, and are valuable as exhibiting an entirely new kind of literature. They are bitter satires, as unrestrained as those of Aristophanes, and aimed at the deep state of degradation into which the Indians had sunk, chiefly through the corruption of the Brahmins. The Dhûrtasamâgama' ("the assembly of rogues") is a playful wrangle between a Brahmin and his scholars about a courtesan. The piece has the merit of parodying in a happy manner the bombastic style of Bhavabhûti, which is a proof that even in India there were critics who were opposed to the common opinion, and who ridiculed the perverseness of the general taste. This little piece belongs to the end of the 15th century. (Published in Lassen's 'Anthologia Sanscritica,' Bonn, 1838.) The later dramas confine themselves entirely to mythological subjects. The greater number of the sixty pieces before mentioned belong to this class. An imitation of the 'Prabodhachandrodaya' is the 'Chaitanyachandrodaya,' a drama in ten acts by Kavikarnapura, in which the life and mystical reveries of the philosopher Chaitanya are celebrated. It dates from the 16th century. Amongst its faults are a profusion of alliterations, and a gorgeously ornate style: but, regarded as an ideal drama—a series of tableaux vivans, presenting faithful portraitures of the adored object of a large body of enthusiasts—the work will always command the esteem of the lovers of literary worth. It was published at Calcutta, 1854.

The 'Gîtagovinda' of Jayadeva, written in the 12th century, is entirely different from the works already described. It is a poem intended for performance at a festival of Vishnu, and belongs to that class to which we ascribed the origin of the drama. It exhibits the separation of Krishna from his wife Râdhâ, his love adventures with the shepherdesses, and the reconciliation of the husband and wife, in a series of songs, which are connected and introduced by strophes which describe the situations. The strophes were intended for recitation, the songs to be sung. This is therefore the only Sanskrit poetry which we possess that can properly be called lyric. But the songs are entirely written on the model of the Prakrit songs, which alone appear to have been intended for singing, and they have throughout the Prakrit metres. The word *govinda* itself is a Prakrit form of the word *gopendra*, "the master of the shepherdesses," which is one of the titles of Krishna. The scholiasts explain the poem in a mystic sense: Krishna is the soul, which emanated from God, with whom it was originally in union, but was drawn down from him by sinful objects (the shepherdesses); at length, however, full of desire for its original purity, it returns to God. In fact, the author himself, in certain passages, seems to intimate that he had some such deep meaning in view: and perhaps we may here find indications of the influence of the mystic poetry of Persia. (Printed at Calcutta, 1806; and there is an excellent edition by Lassen, Bonn, 1836, 4to.)

Narratives.—As the old epic poems were especially designed for the warrior-caste, so the Vaisyas, the third class, have a literature of their own, the *narrative*, of which the first which requires notice is *Fable*. In the 'Râmâyana' and in Manu there are allusions to well-known fables, and others are related in the 'Mahâbhârata.' The two chief works of later times, but which are still of some antiquity, are the 'Panchatantra' and 'Hitopadesa.' [PILPAY, in BIOG. DIV.] The 'Kathânakâs' are short narratives and tale. They are known to us chiefly through three modern prose works, which contain obvious marks of having been derived from older metrical collections. They are called—'Vetâlapanchavinsati,' "the 25 tales of the ghost," by Sivadâsa; 'Sukasaptati,' "the 70 tales of the parrot," known in Europe as the 'Tûtinâmeh,' from a Persian translation; and the 'Sinhâsanadvâtrinsati,' "the 32 tales of the statues on the throne of Vikramâditya." The whole series has only been printed in translations into the modern languages of India. Lassen has published part of the Sanskrit original of the 'Vetâlapanchavinsati,' and the commencement of the 'Sukasaptati,' in his 'Anthologia;' and Prof. R. Roth has given extracts from the Sanskrit text of the 'Sinhâsanadvâtrinsati,' in the 'Journal Asiatique' for 1845, vi. 278, ff. But there is another still more important work, a great collection of all the existing tales, which was undertaken by Somadeva of Cashmere, in the 12th century; it is entitled 'Vrihatkathâ,' "the great narration," or 'Kathâsaritsâgara,' "the ocean of the streams of narrations." It is written in the epic metre, and in a simple style. (About a fourth part of the work has been published by Brockhaus, Leipzig, 1840.) Viewed with reference to their matter, the works of this collection are peculiarly interesting to us, since even in the middle ages they had found their way to Europe under various forms, as 'The Book of the Seven Wise Masters,' &c.; and the knowledge of the original text clears up many difficult questions of literary history. Some of the oldest and best of the 'Tales of the Thousand and One Nights' have been drawn from this source, and even in the Arabic version they retain many features which belong only to India. See Prof. Benfey's translation of the 'Panchatantra,' Leipzig, 1859, 2 vols.

There are two other kinds of narrative works, which need only be noticed briefly: the *champûs*, which are narrations in prose and verse, sometimes written in the artificial style; and the *charitras*, which are short and wonderful stories from the history of some celebrated man. Of this last kind there are two which relate to the kings Vikramâditya and Bhoja, and at first sight appear to contain some valuable information; but they are entirely without authority, and have only served to introduce error into questions of literary history. To the elaborate prose works of this class belong the 'Dasakumâracharitra,' or "the adventures of the ten princes;" and the 'Kâdambari;' the former by Dandi, about the middle of the 11th century, the latter by Vânabhatta, of a somewhat later date, and composed in a very abstruse style. Lastly, in the 'Vâsavadattâ,' a romance in prose, written by Subandhu probably as early as the 7th century, the display of alliteration and the love of ambiguity of import are carried to such an extent that the work may truly be called an entire volume of puns.

Before we proceed to the scientific literature, we must add to the narrative class the scanty remains of

Historical Literature.—The peculiarly contemplative cast of mind which distinguishes the natives of India, and the circumstance of the whole country having never been formed into a single kingdom, but consisting of small independent governments, will sufficiently account for the almost entire want of historical writings. With the exception of a very modern chronicle of Orissa (abridged by Stirling, 'Asiat. Resear.,' xiv.), there is only one historical work in existence in the Sanskrit, 'The Chronicle of Cashmere,' properly entitled 'Râjatarangini,' "the stream of the kings;" it was written in the 12th century by Kalhana, partly from ancient sources, which he specially mentions. There have been three successive continuations of this chronicle, which describe the period of the Mohammedan dominion down to Akbar. The work is written in the artificial style, in the epic metre, and has a good deal of the form of a 'Purâna.' The first part of it has been drawn almost entirely from Buddhist sources. It was first made known in Europe by Wilson's analysis ('Asiat. Resear.,' xv.); afterwards edited at Calcutta, 1835, 4to.; and lastly, the first six books, with a French translation of the whole work by Troyer, were published, at Paris in 1840-52, in 3 vols. The Buddhists, on the other hand, have a history, chronologically worthy of credit, which is continued according to the series of their patriarchs. Hitherto the only publication of the original Indian text has been that of the 'Mahâvansa,' in Pali, by Turnour. (Colombo, 1837, vol. i., 4to.) This deficiency of historical literature is in some degree compensated by numerous inscriptions of various ages, which have been found in all parts of India, and most of which have hitherto successfully been deciphered. As many of them contain genealogies and other matters which indicate the time when they were written, they are of inestimable value for historical inquiries, being almost the only documents which we possess. As to any other historical notices, we are entirely indebted to the writings of the Greeks, the Chinese, and the Arabians, which have been very useful, at least for settling dates.

Scientific Literature.—The sciences to which the natives of India have been original contributors, are philosophy, grammar, and astronomy, together with algebra.

Philosophy is of great antiquity in India. The contemplative character of the natives must have early led them to metaphysical speculations, and the collision which must soon have occurred between the results of those speculations and the revealed word of the Vedas, would become a principal cause of the wider extension of philosophy. Hence arose many systems; of those which are held to be orthodox we are specially acquainted only with six; but as these six are related to each other by twos, they can only be regarded as three distinct systems. We are acquainted with them only in their complete form, in which they have a mutual relation to each other, and we are not able to point out their historical development.

The *Sânkhya* system however must be regarded as the first and most ancient, and this system, on certain mythological grounds, has been traced back to Kapila. It is founded on a duality of soul and matter (or nature); the first being the free, pure, uncreated, and uncreating principle; the second, the creating power of nature, blind and purposeless. The one cannot be thought of without the other; they form for themselves the yet undeveloped being, and from them proceeds, by a regular gradation, from the spiritual to the intellectual, and then to the most corporeal, the whole visible world. Every human being indeed possesses the spirit, but in union with the senses; and his task is, by the conquest of the senses through the medium of the intellect, to attain to the final deliverance, "moksha," or blessedness, which is accomplished in the "jnâna," that is, the "gnosis," knowledge. But this system had an appearance of atheism, and therefore underwent a reformation in the *Yoga* system of Patanjali. It is here established, that knowledge is the way to attain to the final deliverance, but knowledge itself can only be obtained through "yoga," absorption into God and mystical union with him, and a perfect abstraction from everything which can disturb the mind or awake the passions. The system further assumes, that the pure spirit is the creator, and thus it connects itself with the notions which belong to religion; it also adopts the metempsychosis, inasmuch as it fixes degrees of the yoga; the spirit comes back to inhabit new bodies till it has attained the highest degree of the yoga. The Vedas are also held in esteem as means of knowledge, but they are not valued more highly than other means, since a man is to perform what is said in the Vedas freely, and not merely on account of the written word. Hence has arisen the saying, that the "yogin" is exalted above the Vedas.

The doctrines of the Buddhists are founded on the Sânkhya system, which they carry out into all its consequences, both in their religion and politics. [BUDDHA.]

The second system is the *Nyâya*, of which Gotama is the author. This system is entirely confined to logic and dialectic, on which it has been constructed even in the most minute particulars. It is therefore more in accordance than the Sânkhya with the other systems; and as the natives of India generally have bestowed much labour on the study of logic, so philosophers also of all the different sects have occupied themselves with it. The number of the Nyâya writings is very great. The *Vaiseshika* system may be looked upon as a reformation of the Nyâya. It is derived from Kanâda. It applies the logical principle to nature, and has arrived at a complete atomic doctrine by the resolution of all substances into their elements. It asserts that there is a union of atoms, which however is purely mechanical; so that, contrary to the Sânkhya, in its consequences it necessarily leads to materialism.

The third system, the *Mîmânsâ*, the first teacher of which was called Jaimini, is directly opposed to the two former. It maintains religion and the revealed word of the Vedas, and is a positive theological system. Accordingly it is occupied chiefly in commenting upon the Vedas, and in reconciling their contradictions. The first part of this system is predominantly practical; it is called 'Pûrvamimânsâ,' "the first Mimânsâ;" here also it is affirmed that the final deliverance must be worked out by knowledge, but it limits the knowledge to that of the duties prescribed in the Vedas. The metaphysical part of this system is displayed in the *Uttaramîmânsâ*, commonly called the *Vedânta*. Here too knowledge is considered as the condition of deliverance, but still the sacred word of the Vedas is the great rule by which all thought is to be regulated. The Vedânta required philosophy and dialectic, and has therefore adopted from the other systems everything **not contradictory** to its objects; the consequence of which is, that one-half of the philosophy is given up, and the Vedânta is intermediate between philosophy and dogmatism, as was the case in the Christian system of the schoolmen. It has been however of great service in the later corrupted times, in regenerating the old religious and political system, and in maintaining it to the present time. The two greatest restorers of this system were Kumârilabhatta in the 6th century A.D., and Sankarâchârya in the 7th and 8th, both of whom contributed largely to the expulsion of the Buddhists. The latter travelled through the whole of India, combating and refuting the opposite sects. The system is indebted to him for its perfection, and it is even now universally received throughout India in the form into which he brought it.

The heterodox systems ate chiefly known to us through the refutations of them by their opponents, especially Sankarâchârya, for the writings themselves have been intentionally destroyed. They are alluded to in Manu, and they are combated in the 'Râmâyana;' which are proofs of their antiquity. The most important among them is that of the *Lokâyatikas*, a connected continuation and development of the *Vaiseshika* doctrine, and a perfect materialism. Those who adopt this system do not announce a final deliverance as the highest aim, but deny a future existence, and regard the soul as a material substance. The only source of knowledge is considered to be that of a true perception by means of the senses; and the world is held to be uncreated and eternal; they consequently deny the first cause of things, and are perfect atheists.

(Colebrooke, 'Essays on the Religion and Philosophy of the Hindus,' London, 1858, pp. 143-269; Ballantyne, 'Christianity contrasted with Hindu Philosophy,' 1859, pp. xv. xxxviii.; Mullens, 'Religious Aspects of Hindu Philosophy,' 1860, pp. 1-174; Lassen, 'Ind. Alt.,' i. 830-36, ii. 509 f. 1165 f., iii. 421-39; Weber, 'Ind. Lit,' pp. 210-20; Dr. Ballantyne commenced in 1849 to edit at Benares the Sûtras (short aphorisms) of the six principal schools of philosophy, in Sanskrit and English; 'Sarvadarsanasangraha' (short notices of the different systems of philosophy), by Mâdhavâchârya, Calc., 1858; 'Sânkhyapravachanabhâshya,' ed. Hall, Calc., 1856; 'Sânkhyakârikâ,' ed. Wilson, Oxford, 1837; '**Bhagavadgitâ,' ed.** Lassen, Bonn, 1846; Calc., 1856 (with the commentaries of Sankara and Sridharaswâmin); transl. by Thomson, Hertford, 1855; M. Muller, 'On the Nyâya' (app. to Thompson's 'Laws of Thought'); 'Bhâshâ Parichheda,' and 'Siddhânta Muktâvali,' ed. Roer, Calc., 1850; 'Vedântasâra,' by Sadânanda, Calc., 1855; 'Bâdarâyana's Brahmasûtras,' ed. Roer, Calc., 1854; 'Sârîraka Mîmânsâ Bhâshya,' by Sankarâchârya, Calc., 1829, 4to; 'Sankara, sive de Theologumenis Vedanticorum, auct. Windischmann,' Bonn, 1838, 8vo.)

Grammar.—The *Philological Sciences* arise among an ancient people as soon as a sacred literature gives occasion to their growth. The Vedas were written in a language which soon became obsolete. The necessity of defending them against corruption and innovation, and of preserving their correct interpretation, naturally **led to grammatical** inquiries; and as the Sanskrit language is in itself **so original**, regular, and perfect, that its laws are easily discovered, philology has become the most valuable part of Indian literature. The Indian grammarians are far above those of any other ancient people; and they have a strong predilection for this science, and have treated of it in numberless writings. The first beginnings of Sanskrit grammar reach back to very remote times, and are included in the collected system of the Vedas. The oldest grammarians appear also as the authors of the 'Upanishads.' Here too we are unable to trace the gradual formation of the science; the system appears at once in its complete state in the 'Sûtras,' or Aphorisms, of Pânini, who certainly did not live later than the middle of the 4th century before Christ. He takes notice of a series of older grammarians, as well as of schools; and though in certain particulars there was some variation in what they taught, yet in general the system was the same, and they had the same technical terms. The form in which grammar is presented is one peculiar to the natives of India, and they apply the same principles to other sciences, as for instance philosophy. Everything is compressed into rules, which are brought into the most concise forms of expression possible, and the grammatical categories are expressed by a kind of figures or algebraical signs. They are intended to be committed to memory, and without a commentary they are unintelligible; they are all connected one with another. (Published at Calcutta, 1810; at Bonn, 1840, by O. Boehtlingk. A severe criticism on this edition is contained in the introduction to 'The Mânava-Kalpa-Sûtras' edited by Dr. Goldstucker, London, 1861. See also Lassen, 'Ind. Alt.' ii. 479 ff.; Weber, 'Ind. Lit.' p. 199 ff.; Weber, 'Ind. Studien,' i. 141, ff.; **Muller, 'Anc.** Sanskrit Lit.', p. 138, 150 ff.; **Westergaard, 'Om de Œldste Tidsrum i** den indiske Historie.' **Copenhagen, 1860, p. 72 ff.**) Pânini is not systematic, but indeed very arbitrary in his arrangement, which appears to have been adopted merely from the necessity which the object of attaining the greatest possible brevity imposed upon him. The whole of more modern Sanskrit grammar is founded on Pânini, and at first grammarians were merely occupied in explaining and correcting him. Two ancient commentaries by Kâtyâyana (who is also called Vararuchi) and by Patanjali, who in later times have themselves been copiously commented upon, are nearly as old as Pânini himself. In comparatively recent times, grammarians began to take some pains to reduce the 'Sûtras' to a system, and to compose grammars more in accordance with European notions. Here the 'Siddhântakaumudî' must be particularly mentioned, which was written by Bhattojidîkshita about the year 1600, and has served as the foundation of a number of more modern works. ('Siddhântakaumudî,' Calcutta, 1812, 4to.; 'Laghukaumudi,' ibid, 1827, and Mirzapore, 1849.) All these are entirely occupied with teaching the grammatical forms, and it is only as opportunity offers that they give a few syntactical rules. Syntax, on the contrary, is developed in many distinct works, and is grounded on the logic of the Nyâya system, which is a proof of enlarged and correct views. So in like manner the different Prakrit dialects have been exhibited in their separate grammars. The oldest work of this kind is the grammar of Vararuchi, which belongs to the 4th century before Christ (the greater part of it published in Lassen's 'Instit. Linguæ Pracr.,' the whole edited by Cowell, Hertford, 1854); it treats of the principal dialect and of the three others which are most nearly connected with it. He is followed by a series of later grammarians, who successively include within the limits of their works more of the inferior dialects. The most important of these grammarians is Hemachandra, a Jain. The canonical books of the Jains being written in the Prakrit, that language is regarded by them with peculiar interest.

Lexicography also had its origin as far back as the Vedas, for the necessity must soon have been felt of collecting and explaining the obsolete words. A work of this kind, entitled 'Nirukta,' (edited with commentaries, by R. Roth, Göttingen, 1852) forms an essential part of the Vedas themselves. For the purpose of perfecting grammar, it was afterwards found necessary to make alphabetical lists of the verbal roots. The nouns, chiefly for the purpose of fixing the genders, were arranged by themselves, not alphabetically, but according to the subjects to which they belonged. The chief work of this class, which has served as a foundation to all the later ones, is the 'Amarakosha' ('Amarasinha'), which they have imitated even in their arrangement. [AMARA, in BIOG. DIV.] Next in celebrity and more complete than the before-mentioned is Hemachandra's 'Abhidhânachintâmani,' from the 12th century (edited by Boehtlingk and Rieu, St. Peterb., 1847). None of these works, of which there are many, completely exhausts the treasures of the language.

Metre.—In like manner, the *Veda-hymns*, which were to be committed to memory, led to the consideration of the laws of metre, and treatises on metre have been ascribed to very early teachers of the Vedas. Here also the more early essays, such as the Nidâna-sûtras of the Sâma-Veda, have been superseded by a work which exhibited the subject as a complete system. Pingala, who is commonly considered to be the same as Patanjali, is said to be the author of it: this work, which, like the whole science, is called Chhandas, has been elucidated by numerous commentaries.

Music.—The theory of music has also been elaborated according to various **systems, but in a strange** manner, for the different notes and **musical scales have been personified.**

Of the musical sciences nothing has been printed except quotations from Bharata's 'Gândharvaveda,' and from the works of Îsvara, Nârada, Pavana and Kalinâtha in the commentaries to the dramas. But several treatises, such as the 'Sangitaratnâkara' by Sârngadeva, the 'Râgavibodha' by Soma, the 'Sangitadarpana' by Dâmodara, the 'Râgamâlâ,' exist at least in manuscript. ('Catal. Codd. MSS. Sanscr. in Bibl. Bodl.', Oxford, 1859, p. 199-201.) See also Colebrooke's copious Treatise on Metre ('Asiat. Res.', x.).

Rhetoric.—To the philological sciences belongs also the Indian system of *Rhetoric*, or rather *Poetry*, in which the rules for poetic composition are deduced, not from any principles of art, but from the existing classical works, with particular reference to the drama, the theory of which is extremely copious, and goes into the nicest distinctions. This theory belongs to a late period. There have been printed the 'Kâvyaprakâsa,' by Mammathabhatta,' of Cashmere (Calcutta, 1829), and 'Sâhityadarpana,' by Kavirâja (Calcutta, 1853), both of which belong either to the 12th or 13th century.

Commentaries.—In later times the Indian grammarians have occupied themselves in writing commentaries, particularly on the works belonging to the Vaidic literature, to classic poetry, and to philosophy and grammar. The most important of the scholiasts with whom we are yet acquainted are Sâyana, Mahîdhara, Sankara, on the first mentioned, Mallinâtha, on the more modern epic poems, and a host of others. The commentators have done good service in fixing and maintaining a pure text, especially in the Vedas and the great epic poems. A philological school was established in Bengal, upon a directly opposite principle, for they began to make editions of classical works, in which most uncritically, according to European notions, they kept to the meaning, but took the liberty of entirely altering the expression. As we have before mentioned, they made such a recension of the

'Râmâyana,' as well as of the 'Sakuntala,' and other dramas. Vopadeva, a grammarian of this school, in a similar manner invented a new grammatical system, according to which he altered the technical expressions of Pânini, without in other respects varying in the smallest degree from this method. ('Mugdhabodha,' Calcutta, 1826, St. Petersburg, 1847.)

Astronomy.—The oldest Indian astronomical documents are the calendars which are annexed to the Vedas, and which, according to Colebrooke, belong to the 13th century B.C., but are at least in their present form, of much more recent date. They include a solar year of 365 days, and are so composed as to determine it correctly. Here also we are unable to point out how the mathematical and astronomical sciences were gradually developed from such simple elements, as we possess them only in their perfected form. Assisted by the system of notation which they discovered, the natives of India have been particularly happy in their methods of treating arithmetic and algebra, which have had such influence on their mathematical studies that they prefer solving geometrical questions analytically, just as the Greeks, on the contrary, solved arithmetical questions by geometry. ('Lilâvati,' by Bhâskara, Calcutta, 1828; Colebrooke, 'Algebra of the Hindoos,' Calcutta, 1817, 4to.).

In the earliest works on Indian astronomy now extant, several different systems are apparent, and these systems have been treated of in five works, entitled 'Siddhântas,' which apparently contain the same theories which were afterwards successively extended and improved. Varâhamihira, at the beginning of the 6th century A.D., compared them with each other, and other astronomers worked them up again under different titles, each with the view of introducing into them his own theory. The most important of all astronomers that preceded Varâhamihira is Âryabhatta, who was the first to free himself completely from all mythological notions; he was acquainted with the motion of the earth about its axis, and estimated more accurately than Ptolemy the precession of the equinoxes. His work, 'Âryâshtasata,' an exhibition of his system in 800 strophes, has not yet been recovered, but his abridgment of it, 'Dasagitaka,' and another work, 'Aryabhattiya,' which in 4 chapters and 123 strophes contains his system of mathematics, are still extant. According to Colebrooke's reckoning, the latest period at which he can be fixed is 478 A.D., and he may have lived two or three centuries earlier; and Whish ('Trans. Asiat. Soc.', iii. 2, 509), fixes the year of his birth about 502 A.D. By the researches of Weber ('Ind. Stud.', ii. 236 ff.; 'Ind. Lit.' p. 221 ff.) and Lassen ('Ind. Alt.', ii. 1114-46) the question whether the Indian astronomy was entirely native, or whether it was constructed with the aid of that of the Greeks, has been finally settled in favour of Greek influence. Âryabhatta, who most probably flourished as early as the beginning of the 4th century A.D., availed himself largely of the progress which the Greeks (especially Hipparchus) had made in astronomy; and he not only improved upon their new theories and inventions, but added also the results of his own independent investigations. In algebra he made even greater progress than the Greeks. Astronomy has not been improved in India since his time; on the contrary, those who have come after him have not relinquished the false views consecrated by religion, but have endeavoured to defend them against him. This was chiefly done by Brahmagupta, the author of the 'Brahmasiddhânta,' in the 6th century A.D., who is the classical astronomer of the moderns, and whose track was followed by Bhâskara in the 12th century, in his work 'Siddhântasiromani.' Since one of the other Siddhântas, the Sûryasiddhânta, has lately been edited in Calcutta (1859), and an excellent translation of the same has appeared in the sixth volume of 'The Journal of the American Oriental Society,' (1860) p. 141-498, we have the means to make ourselves acquainted with all the peculiar features of Hindu astronomy. (See several discussions by Colebrooke in the second volume of his 'Essays,' and an article by F. E. Hall, on the 'Ârya-Siddhânta' in the 'Journ. Am. Or. Soc.', l. l. p. 556-64.

Medicine.—There are many Indian works on medicine, and the systems are various. Many parts of the medical science of India are valuable even to us, as for instance the Materia Medica, in which they were much favoured by nature. The Indian physicians were highly esteemed by the Greeks. In surgery especially they have made considerable progress, and have even discovered and performed difficult operations, as for instance the restoring of noses. The most celebrated medical work, 'Susruta,' has been printed (Calcutta, 1835, 2 vols. 8vo); and Ainsley ('Materia Indica,' London, 1826 and 1831), and more recently Royle, ('On the Antiquity of Hindu Medicine,' London, 1837), and Wise ('Commentary on the Hindu System of Medicine,' Calc. 1845), have done much to make known the Indian systems of medicine.

Natural History.—The observation of external nature still remains in a very low state among the natives of India, and they seem never to have made any progress even towards the commencement of a scientific system of natural history; at least no works of this kind are known.

Study of Sanskrit.—The Sanskrit language was for many years considered unattainable, but towards the close of the last century this study received a powerful impulse, partly from the necessities of the English government in India, and partly from a desire of knowledge among the learned of Europe. The study of the language having been once commenced, its progress was extremely rapid, the acquisition of it being much facilitated by the previous labours of native grammarians; and by the printing of a great number of their most important works, a large part of the literature became generally accessible, an advantage which most of the other oriental languages have not enjoyed. In India this progress has been connected with the names of Wilkins. Jones, Colebrooke, Wilson, Mill, Prinsep, Roer, Hall, R. Mittra, Râdhâkânt Deb. But Europe has not remained behind; and the rich collections of manuscripts in the possession of the East India Company in London, of the Bodleian at Oxford, of the Royal Library at Berlin, and of the Imperial Library of Paris, have been abundant sources, and perhaps more than sufficient to compensate for the peculiar advantages enjoyed by India. In England, the study of Sanskrit was in the first place most indebted to Haughton and Rosen [ROSEN, in BIOG. DIV.]; it now counts among its Sanskrit scholars such men as M. Muller, Goldstucker, Ballantyne, M. Williams, and Aufrecht. In France, it was chiefly introduced through Hamilton in 1804, and cultivated by Chézy and Burnouf. In Germany however Sanskrit has experienced the most cordial reception, though at first, owing to the want of manuscripts, the study of it was prosecuted under the greatest disadvantages. In that country, the knowledge of Sanskrit was chiefly diffused by A. W. von Schlegel and Bopp, both of whom learnt it about the same time in Paris. At present there is hardly a university or college that has not its chair for Sanskrit; and of the success with which it has been studied, the works of Lassen, Roth, Weber, Stenzler, Brockhaus, Benfey, Kuhn, and Spiegel, give abundant proof. Also in other continental countries Sanskrit scholars of eminence, such as Westergaard in Denmark, Boehtlingk and Schiefner in Russia, Regnier in France, Nève in Belgium, and Gorresio in Italy. have done much to promote and popularise the study of ancient Indian literature.

For the *practical study* of Sanskrit we would recommend the following books:—

a, Dictionaries: Wilson's, 2nd ed., Calc. 1832; 3rd ed. by Goldstücker (in the course of publication)); 'Sanskrit-Wörterbuch,' by O. Boehtlingk and R. Roth, St. Petersburg, 1855 ff. (in the course of publication); 'Engl. and Sanscr. Dict.', by M. Williams, Lond. 1851.

b, Grammars: Wilson, 2nd ed., London, 1847; Williams, 2nd ed., London, 1857; Bopp, 'Grammatica critica linguæ Sanscritæ,' Berlin, 1829-32, and his 'Kritische Grammatik der Sanskrita-Sprache,' Berlin, 1845; Boller, 'Ausführliche Sanskrit-Grammatik,' Wien, 1847; Benfey, 'Vollständige Gramm. der Sanskrit-sprache,' Leipzig, 1852, and his 'Kurze Sanskrit-Grammatik,' Leipzig, 1855; Desgranges, 'Grammaire Sanscrite-Française,' 2 vols., Paris, 1845; Oppert, 'Gramm. Sanscrite,' Paris, 1859; Rodet, 'Gramm. abrégée de la langue Sanscrite,' Paris, 1860; Flechia, 'Grammatica Sanscrita,' Torino, 1856.

c, Readers: Johnson, 'Selections from the Mahâbhârata,' London, 1842; 'Sanskrit-Chrestomathie,' by O. Böhtlingk, St. Petersburg, 1845; 'Anthologia Sanscrita,' ed. Lassen, Bonn, 1838; 'Chrestomathie aus Sanskritwerken,' by Th. Benfey, Leipzig, 1853.

d, Works on comparative Grammar: Bopp, 'Vergleichende Grammatik des Sanskrit, etc.', 2nd edit., Berlin, 1856-61, 3 vols.; translated into English, London, 1854, ff., 3 vols.; Bopp, 'Glossarium Sanscr.,' Berlin, 1847; Kuhn, 'Zeitschrift für vergleichende Sprachforschung,' Berlin, 1852 ff., 10 vols.; Kuhn and Schleicher, 'Beiträge zur vergl. Sprachforschung,' Berlin, 1858-61, 3 vols.; many articles in the 'Transactions of the Philological Society.'

SANTALIC ACID. [SANTALIN.]

SANTALIN ($C_{30}H_{14}O_{10}$?). *Santalic acid.* The colouring matter of the *Pterocarpus santalinus*, or red sandal-wood. It was examined by Pelletier in 1814, and is readily obtained by digesting the rasped wood in alcohol, and then diluting the clear solution with water, by which the solution is precipitated of a beautiful red colour; it is tasteless, nearly insoluble in water, but readily dissolved by alcohol, ether, alkaline solutions, and slightly by the oils of lavender and rosemary.

The alcoholic solution of santalin gives different coloured precipitates with metallic solutions: thus with tin it gives a beautiful purple, with lead a violet, iron a deep brown, silver a reddish-brown.

Santalin reddens litmus-paper, and forms ill-defined salts with some bases.

Santalin, or rather the red sanders which contains it, is little used in this country as a dye stuff, but in India it is employed both in dyeing silk and cotton. It is used in pharmacy to give a colour to certain tinctures, but the colour is not generally regarded as a permanent one.

SANTONIC ACID ($C_{30}H_{18}O_{6}$?) *Santonin.* A vegetable principle possessing acid properties obtained from the seeds of the *Artemisia santonica*, or southernwood. Its properties are, that it is colourless, crystallises in six-sided prisms and some other forms, is destitute of smell, and when long chewed is slightly bitter. It is soluble in 4000 to 5000 times its weight of cold water, and 250 times when boiling. It is soluble in alcohol, and in the fixed and volatile oils. When strongly heated, it is decomposed. The alcoholic solution reddens litmus-paper, and with some bases it forms neutral and crystallisable salts; this is the case with santonate of soda and santonate of lime; some of the metallic santonates are soluble and others insoluble in water. None of them is applied to any use.

SANTONIN. [SANTONIC ACID.]

SAP is a mode of executing the trenches at the siege of a fortress, when the besiegers arrive within such a distance from the covered-way that the fire from thence becomes too dangerous to allow the men to work on the ground without being protected by some covering objects, as gabions, placed between themselves and the enemy.

The process of sapping varies with the distance from the works of the fortress and the degree of activity with which the fire of the defenders is kept up. It is, therefore, divided into what is called the *flying sap* and the *complete* or *full sap*. In ordinary circumstances, in sieges, before the introduction of rifled ordnance or rifles to any great extent, the flying sap began to be used in forming the second parallel trench, which may be about 320 yards from the covered-way; and it is executed in the following manner.

If the distance from the depôt of siege-materials to the place of the intended trench is not too great, every man carries two gabions, one on each side of him, or both slung at his back; he carries also a pickaxe and a spade, and in the first case these are fixed in the gabions, but in the latter he carries them in his hands. If the distance which the working party has to march is considerable, this burden would be too fatiguing, and then each man carries on his shoulder one gabion together with a pickaxe or a spade. Carrying the gabions one on each side has the advantage of permitting the man to carry his musket slung. The work is begun at night, and when the sappers have arrived at the ground where the tracing-line for the intended trench has been laid down, they set up their gabions a few inches in front of that tracing-line, the officers observing that the row of gabions in its whole length is correctly placed. The portion of trench to be executed by each sapper, or workman, is equal in length to the space covered by two gabions (about 4 feet): the men sit down or otherwise keep themselves covered till the order is given to commence digging, and when the number of men who constitute the working party is greater than suffices to allow one man to every two gabions, those who have not room to work retire to a little distance till they are required to relieve the others. A man may fill his two gabions with earth in about a quarter of an hour, and then they will be proof against a musket bullet, except at the place where they touch each other; after this the earth obtained in executing the trench is thrown beyond the gabions towards the fortress. During the progress of the work the gabions are pushed a little way outwards at the top, in order that they may effectually resist the pressure of the earth which they are to retain; and they are sometimes crowned by two or three rows of fascines which are laid upon them in a direction parallel to the trench.

If the work proceeds by day and night, the parties are relieved every eight hours; and a trench executed by flying sap may, in soil of medium tenacity, be completed by three reliefs of men.

When the approaches of the besiegers have advanced so near the covered-way that the fire of the defenders will no longer permit the men to bring the gabions openly to the ground, the full sap is practised. For this purpose the sappers are divided into brigades of eight men each; and of these a demi-brigade only of four men is employed in the formation of a single line of trench. The party is provided with a mantelet (a plate of iron thick enough to be musket-proof, and capable of being moved forward by being mounted on small wheels) by which the men may be covered in front; or, instead of this machine, there is provided for the same purpose a great gabion called a sap-roller. This is a cylinder of basket-work, 6 feet long, and about 4 feet diameter, and having within it a gabion of equal length, but about 2 feet six inches diameter; the axes of the two gabions are coincident, and the space between the exterior of the one and the interior of the other is stuffed with fascines, by which means it is rendered musket-proof. The sap-roller turning on its convex surface is found to be more manageable than the mantelet; and when it is intended to form a trench in any proposed direction, by breaking out from one which has been already executed, it is raised over the parapet of the latter trench, and gradually lowered on the exterior side, being guided by means of a hook, so that it may have a position perpendicular to the line of the intended trench. The leading sapper of the demi-brigade then cuts through the parapet, and pushing the sap-roller forward about 2 feet, he hastily places an empty gabion in rear of that extremity of the sap-roller which is nearest to the enemy's work, in order that he may be covered on his flank: then kneeling behind the gabion, he excavates a portion of a trench, 18 inches wide, and as many in depth, leaving a berme about 12 inches broad between the gabion and the nearest edge of the excavation, and throwing the earth into the gabion. When this portion is dug, the sap-roller is advanced about 2 feet farther, and another gabion is set up in its rear, adjacent to the former, and in the line of the intended trench; a short fascine or two sand-bags (bags full of earth), are placed one above another in the hollow between the two gabions, in order that a musket-ball may not be able to penetrate through the screen in that part. The sapper then excavates as before, and having filled the second gabion, a third is handed to him, which he places and fills as he continues to advance. The second sapper of the squad follows the first, keeping a little way in his rear, and increases the width only of the trench by 20 inches on the side which is farthest from the line of gabions, and he also throws the earth into and beyond the gabions. The third sapper follows, and increases the depth only by 18 inches on a breadth of 20 inches measured from the rear side of the trench towards the gabions; and the fourth sapper excavates a portion 3 feet deep, increasing the breadth of the trench towards the rear by 10 inches. By this arrangement the tasks of the different men are rendered nearly equal, and complete cover is obtained when the work of the third man is executed. The four men thus form a trench 4 feet wide and 3 feet deep, and a step is left on the side nearest to the gabions for convenience in standing to fire over the parapet. The working parties from the infantry of the line afterwards complete the trench by increasing the width to its usual extent, about 12 feet.

Since the head sapper has the most dangerous post, the second, third, and fourth sappers relieve him by alternately taking his place; and the work advances about 8 or 10 feet per hour, according to the tenacity of the earth.

If the fire of the place should be considerably subdued by the action of the besiegers' batteries, the full and flying sap may be combined in order to expedite the approaches. Thus a party of sappers advancing on their hands and knees, and rolling gabions before them, on arriving at convenient places set up the latter in line; then two or three men, at certain intervals from each other, dig pits behind the gabions, in order to get cover, and afterwards work towards each other, making a small trench, and filling the gabions with earth. The trench may subsequently be made of the required width.

When the distance to be passed over to the work attached becomes very small, the angle formed by the adjacent zig-zags becomes very small, or rather when 100 yards of the zig-zag does not carry the approaches so much as 32 yards in advance (those being the proportionate rates at which the single and double sap can be executed), then the line of trench is carried on directly towards the place, sometimes by a simple trench with traverses at intervals, and sometimes by what is called the double sap. This is performed by two squads or demi-brigades, who work parallel to each other, each being covered in front by its own sap-roller, and there is a third roller in rear of the small interval between the others. A row of gabions is placed on the right of the trench executed by one squad, and on the left of that which is executed by the other; the distances between the rows of gabions is about twelve feet, and traverses are formed in the trench at intervals as the work advances. These project alternately from opposite sides, so as to leave a serpentine passage along the trench. Hence this is termed the *serpentine* sap. There is however another form of double sap, called Jebb's, or the double direct sap, which is now adopted in the English service. This is formed by three brigades of sappers with four sap rollers in front. The three brigades work parallel to one another, and drive three saps straight forward. Traverses are formed as the sap proceeds, projecting alternately from each side like teeth and overlapping one another. The intermediate space is then excavated, and a covered passage is thus obtained. The distance between the parapets on each side is 22 feet, or the breadth of eleven gabions.

SAP-GREEN, a pigment, prepared by evaporating the juice of the berries of the *Rhamnus catharticus*, or buckthorn, to dryness, mixed with lime. It is soluble in water, less so in alcohol, and insoluble in ether and oils. Acids redden it; but the alkalies and alkaline earths restore the green colour. [COLOURING MATTERS.]

SAPOGENIN. [ESCULIC ACID.]

SAPONIC ACID. [ESCULIC ACID.]

SAPONIFICATION. [FATTY ACIDS.]

SAPONIN. ($C_{24}H_{20}O_{14}$?) A colourless non-crystalline body, found in the soapwort (*Saponaria officinalis*) and many other plants. The *senegin* of Gehlen appears also to be identical with this substance. Saponin is extracted from the root of the soapwort by boiling alcohol from which it is deposited on cooling. It is inodorous, tastes at first sweet, then astringent, and finally acrid. It is soluble in water in all proportions, forming a remarkably saponaceous solution. It is almost insoluble in ether and in absolute alcohol, but readily dissolves in dilute alcohol. Lime-water does not precipitate aqueous solutions of saponin. Introduced into the nostrils a very minute quantity of powdered saponin occasions violent sneezing. [ESCULIC ACID.]

SAPPAN WOOD. [BRAZIL WOOD.]

SAPPERS AND MINERS, ROYAL, formerly the name given to the non-commissioned officers and privates of the corps of Royal Engineers. The men and officers are now collectively termed the Royal Engineers, but in specifying any individual private he is termed sapper — of the — company of Royal Engineers. They are employed in building and repairing permanent fortifications, in raising field-redoubts and batteries, in making gabions and fascines, in digging trenches [SAP], and executing galleries of mines during sieges, and also in forming bridges of rafts, boats, and pontoons.

The troops belonging to the department of the engineers were first embodied at the termination of the war between Great Britain and her American colonies, and they then received the designation of Royal Military Artificers. The duke of Richmond, who was at that time master-general of the ordnance, formed them into independent companies, and caused them to be stationed chiefly at Portsmouth, Plymouth, Chatham, Dover, and Gibraltar. In the year 1807 the Military Artificers constituted a corps of 32 companies, each consisting of 126 men; and a sub-lieutenant was attached to each company, which was placed under any senior captain of engineers who might happen to be where the company was stationed. But the want of a proper organisation, and of officers permanently attached to the troops, gradually brought on a relaxation of discipline and a neglect of the particular duties for which the men were intended; it is even said that when detachments were to be drawn from the companies for any intended expedition, the engineer officers who selected the men sent only those who were the least efficient, and that consequently, during the first years of the war against the French in Spain, the service suffered much from the inexperience of the troops of this class.

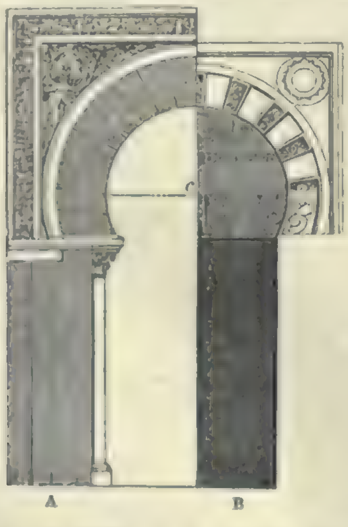
After the failure of the attack on Badajoz, in 1811, it was proposed to select some companies from the corps of Royal Military Artificers, and to form them into a body expressly for the purpose of executing field-works; and in the following year this proposal was carried into effect. Lieutenant-General Mann, who was made inspector-general of fortifications, obtained permission to have the name of the whole corps changed into that of Royal Sappers and Miners; and lord Mulgrave then formed at Chatham the institution at which the men have ever since been regularly instructed in all the duties connected with military engineering. The junior officers of engineers were at the same time appointed to act as the regimental officers of the companies. This institution has been from the first (April, 1812) under the direction of Colonel, now General, Sir Charles Pasley, K.C.B., an eminent officer, who as an engineer had previously distinguished himself in the service of his country.

A detachment, consisting of 300 men, was sent, in 1813, to perform the duty of sappers and miners at the siege of St. Sebastian, where they rendered essential service. In 1814 a brigade of engineers was attached to every division of the army; each brigade consisted of a company of sappers and miners, with horses and carriages sufficient to convey the tools necessary for the work of 500 men; and five companies of sappers and miners served with the pontoon train, which consisted of 80 pontoons, with the forges, waggons, &c. The whole corps was under the orders of a brigade-major of engineers.

From 1812 to the peace in 1814, the corps of sappers and miners amounted to 2861 men; and during the hostilities in 1815, it consisted of 2421 men. At present it consists of 36 companies, and 4337 men, exclusive of officers; and, besides the regular course of instruction in sapping, mining, making gabions, fascines, &c., the men are taught the most elementary principles of fortification, the manner of drawing plans and sections of buildings, and, to a certain extent, the art of land-surveying. Several of the companies are employed in the colonies in the exercise of their professional duties; and of those which remain in this country, some are engaged under the officers of engineers in the mechanical operations connected with the ordnance survey of Great Britain and Ireland which is being carried on by the war department; parties of the corps also regularly attend the Royal Academy at Woolwich and the Military College at Sandhurst, where they assist to execute, for the instruction of the gentlemen-cadets, the several works connected with the practice of field-fortification. It ought to be mentioned that the troops of the corps have invariably, in whatever part of the world they have been employed, conducted themselves as intelligent men and steady soldiers.

SARACENIC ARCHITECTURE, is the term usually applied in this country to what would perhaps be better named Mohammedan architecture, since it embraces the architecture of all Mohammedan peoples, or Arabian architecture, from the race with whom it originated. But though the style may be traced back to them, the Arabians cannot be considered as themselves the inventors of it. They had in fact no distinctive style of their own, when the rapid spread of the religion of Mohammed and the conquests of his followers rendered necessary the erection of numerous religious edifices, and called into existence a new style of architecture. Mohammed is said to have built a mosque at Medina, but it was a structure of the simplest kind, and he left no directions in the Koran for the guidance of his disciples in erecting others. Hence, as has been often pointed out and is now generally admitted, the Mohammedans wherever they secured a standing adopted the architecture of the subjugated race. Thus in Persia we may clearly trace in Mohammedan buildings the older Persian type; in India (as was observed under INDIA, ARCHITECTURE of) that of the Hindus; in Spain the debased Roman or early Romanesque; in Egypt, Syria, and Turkey, the Byzantine; but everywhere this native character was modified and adapted, overlaid with a certain exuberant oriental fancifulness, imbued with Mohammedan feeling: in short combined with a new and foreign element, instead of being prosaically copied as it stood; and thus was rapidly evolved a distinct and well-characterised style.

Fig. 1.



What may be regarded as the typical varieties of the earlier Saracenic architecture are those which appeared in Spain in the 8th century of the Christian era, and in Egypt somewhat earlier: its later form appeared in Constantinople. In each of these a striking and distinctive feature is the horse-shoe arch. But this though a peculiar is by no means a constant feature of the style, or used to the exclusion of other forms of arches. On the contrary there are several varieties, and among them is the pointed arch, which is already a well-established form in the mosque of Ahmed Ibn Tooloon, erected at Cairo in the 9th century, and is of frequent occurrence in other Mohammedan structures erected in that city in the 10th century. The arch being so essential a characteristic of the style we give a few of its various forms in the annexed figures.

Fig. 1 is an example of the horse-shoe form, having the centre *c* on the diameter of the arch raised above the chord or spring of the curve (the dotted line), and consequently the curve itself is greater than a semicircle. The same figure further exemplifies some differences of application, the side or half A showing the arch supported on columns, the other without columns; besides which it illustrates other variations; for on the side B the head of the arch is closed over a square-headed aperture not wider than the span or chord; whereas on the side A the opening between the columns is as wide as the diameter of the arch itself in its greatest width through the centre *c*.

Fig. 2 is an instance of a pointed horse-shoe arch, it being struck from two centres, which, as in the other case, are elevated above the line of the impost, or spring, from which the curve commences. This figure also exhibits two varieties of decorations, both of them by scalloping; one half being scalloped on the intrados, or edge of the

Fig. 2.

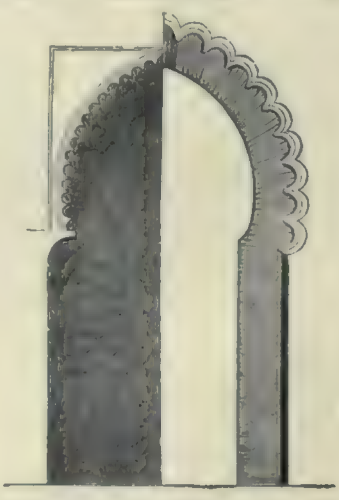


Fig. 3.

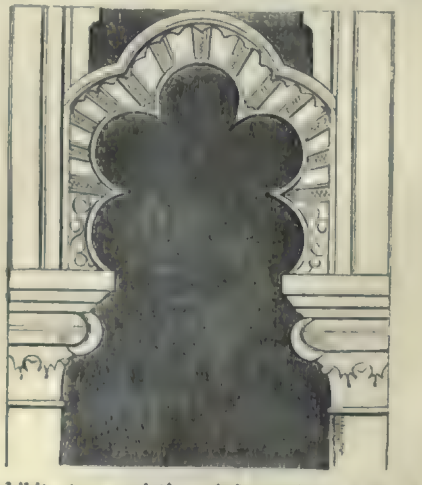
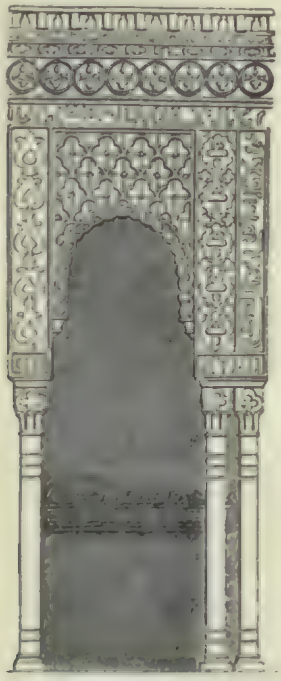


arch itself; and in the other, the extrados, or outer circumference, being so cut, or more properly speaking, the edge of the face of the wall within which the arch recedes: of which kind is the gate in what is called the Casa del Carbon at Granada.

The next example is of what may be called the cusped or scalloped arch, strictly so termed, the outline being produced by intersecting semicircles, similar to the trefoil-headed compartments in our Gothic windows; but beyond that general resemblance, which certainly goes some way to confirm the opinion that the Gothic style borrowed something from the Saracenic, the character is altogether different, not only because it is here the whole arch which is so shaped, instead of merely a subdivision within a larger opening, but also both on account of the external moulding following the same form, and of quite a different mode of decoration. In Gothic architecture the spandrels, or triangular spaces between the foils, are panelled with splayed surfaces uniting in the centre. Arches of the kind here shown occur in the sanctuary of the great mosque at Cordova (8th century), where they rest upon columns which both in their capitals and shafts bear considerable similarity to Corinthian ones, except that they are shorter and without bases, and are therefore very different from the slender pillars peculiar to Arabian architecture.

Fig. 4 exhibits an example of such pillars, and also another variety of Saracenic arches (from the Court of the Lions in the Alhambra, 13th century) very unlike any of the preceding specimens, it being circular-headed, and *stilted*, that is, it is considerably more than a semicircle, its height in fact almost equal to its breadth, but, instead of contracting downwards, like the horse-shoe form, it is continued down straight to the impost, whereby the arch or semicircle has the appearance of being raised or *stilted*, and made loftier than the arch itself would else be. It also exhibits another peculiarity which the Arabs seem greatly to have affected, namely, *corbelling*, or resting arches upon brackets which serve as their imposts; owing to which such arches have the appearance of being suspended over the opening below, which becomes wider and the support or pillar slenderer in proportion to the projection given to the corbels.

Fig. 4.



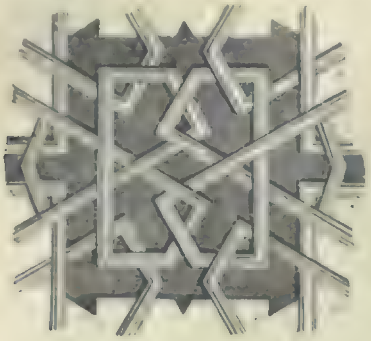
The above will suffice to show the principal varieties, in which we have chiefly attended to the form of the arches themselves, without attempting to show detail and decoration, to which it would be impossible to do any sort of justice upon so contracted a scale, although it may serve for mere explanation. As supplementary however to what has been said, it should be observed as one characteristic of the style, that whatever their shape, or however applied, arches are generally placed within a square-headed panel or compartment, variously ornamented, and frequently surrounded with a margin or border similar to the square label in Gothic architecture. Sometimes there are two margins or labels, and the space between them is filled up either with inscriptions or other decoration. This mode however was confined to large arches, not supported upon columns, but forming an opening through a wall, for a gate or door; and it was for such purposes that the horse-shoe arch was chiefly used, particularly for entrances to mosques. These were further distinguished by the breadth and richness of the archivolt or border surrounding the arch; and which was sometimes equal to the radius or semidiameter of the curve. In some instances the whole archivolt was uniformly decorated; in others only at intervals, or on the alternate voussoirs or arch-stones, some idea of which may be obtained from B, *fig.* 1.

Pillars are commonly of exceedingly slender proportions, almost to apparent insecurity; but owing to the style of the embellishment this lightness of particular forms tends to heighten the general luxuriance. Some have imagined that this element of slenderness in regard to pillars indicates a tent origin of the style; and that while the pillars themselves were fashioned in imitation of the poles which supported the awning, the idea of the latter was in a measure kept up by the general decoration of various devices in mosaic work, and painted stucco, or glazed tiles, which gave to the whole the semblance of being covered with richly-patterned carpeting or embroidered tapestry; not indeed in exact imitation or so as to aim at illusion, but with just that degree of adherence to a prototype which is observable in all artist-like architectural decoration. This tent-like character it has been suggested was further kept up by concave ceilings and cupolas, emblazoned with painting and gilding. The whole surface, in fact, was frequently broidered over with decoration, which consisted almost entirely of ornamental patterns composed either of foliage or geometrical figures, though occasionally with an intermixture of both. The decorations of the former class have given rise to the modern term *Arabesques*, as indicating scroll-work and foliage ornament filling up a frieze or compartment, although it is not very correctly applied, being usually intended to express a combination of animal and vegetable forms, human figures, and those of birds and quadrupeds terminating in foliage and flowers; whereas no such mixture occurs in Arabian architecture, all imitation of the human or even animal shape being interdicted by the Mohammedan law. Their geometrical patterns exhibit singular beauty and complexity, inexhaustible variety of combinations, and a wonderful degree of harmonious intricacy, arising out of very simple elements; to which must be added the variety produced by colour also, whereby the same arrangements of lines and figures could be greatly diversified. Hence though apparently quite unmeaning, and intended only to gratify the eye, such embellishment must have powerfully recommended itself to a people both imaginative and contemplative, and whose fancy would find occupation in patiently tracing and unravelling the manifold intricacies and involvements, the mazes of what at first sight looks like a mere labyrinth, until its scheme unfolds itself; but merely momentarily as it were, being again lost when attention is diverted from it to particular parts. It is on this account that Hessemer, Jones, and others who have paid special attention to the subject, assign so very high a value to Arabian decoration, as being strictly ornamental and strikingly characteristic.

One very prevalent and very peculiar element of Arabian decoration is the use of inscriptions evidently with reference to their ornamental effect. So far there is a very striking analogy between the practice of the Moslems and that of the ancient Egyptians; if the latter covered the walls of their edifices with hieroglyphics, the others inscribed theirs no less profusely with sentences; and the characters of their ordinary writing, elegant and fanciful in themselves, were as studiously ornate and calligraphic as possible; and so well do they harmonise with the rest, as to seem to belong to the embellishment, and to have sufficient value as such independent of their meaning. Neither was the effect of colouring and gilding wanting to set off the inscriptions in the most brilliant manner. The colours chiefly used were the primaries, red, yellow, and blue; the secondaries, except in the decline of the style, being only used in the lower and subordinate parts of buildings. The use of these colours appears to have been most profuse; gilding was also freely employed. In short, even by those who consider much of it to have been in false taste, architectural decoration must be allowed to have been carried by the Arabians to a very high pitch; and although it may be too florid, too prodigal, too *inflated*, and overlaid with ornament, it well deserves to be studied, as many ideas may be derived from it, for novel combinations both of forms and colours. And for such study ample materials are supplied by Mr. Owen Jones's splendid work on the 'Alhambra,' and Hessemer's 'Arabische Bauerzierungen;' in both of which publications the plates exhibit the original colours. The general reader will hardly need to be reminded that Mr. Jones's admirably executed Alhambra Court at the Crystal Palace affords a means of examining copies the actual size, made from casts taken by Mr. Jones at the Alhambra, of the finest and most elaborate examples of Moorish ornamental work at its most advanced stage; but we may point out that the little 'Handbook of the Alhambra Court,' written by Mr. O. Jones, contains much valuable information on the principles of Saracenic ornamentation, and indeed on the second period of Saracenic architecture generally.

Lattice or open trellis-work was another fertile source of embellishment, and was very much akin to the perforated tracery frequently met with in Gothic buildings. In this respect the two styles display great similarity of taste, distinguishing themselves herein from almost every other, notwithstanding that each has a peculiar character of its own. But in Saracenic architecture the interstices are smaller, and the design fills the whole of one aperture; whereas in the Gothic style the ornamental tracery is confined to the heads of windows. Besides which, the character of Saracenic tracery is altogether different, it being composed of straight lines, frequently so disposed as to form stars in some parts of the design. As far as an idea of the peculiarities of the style in this respect can be formed from a single specimen, the example here annexed (from Hessemer) of a portion of a window in the mosque of Hakim at Cairo, may be of some assistance. The pattern is rich and playful; and notwithstanding that, although regular, it appears at first sight to be rather complicated, will be found to be composed of merely a repetition of the same forms, yet producing a constant variety, according as the lozenge or the star is fixed upon by the eye as the centre from which the rest of the pattern diverges.

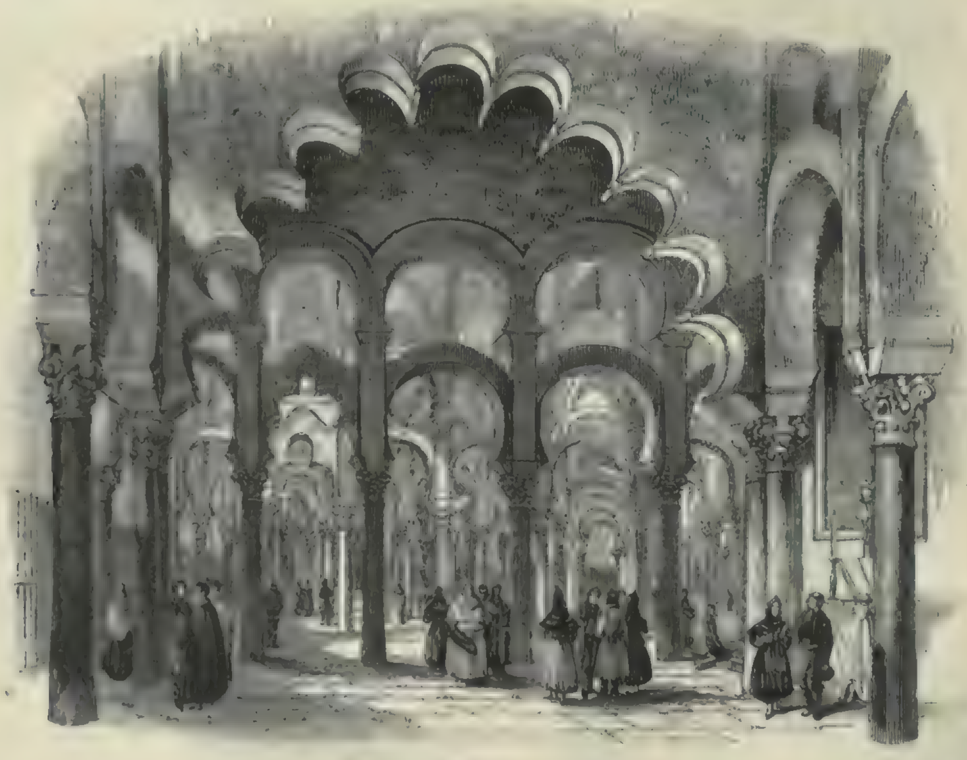
Fig. 5.



Of perforated battlements and parapets, this style furnishes some exceedingly rich and tasteful specimens. Several of them are exceedingly intricate and delicate also, and may therefore, almost without exaggeration, be compared to lace-work as seen against the sky. Of this kind are the parapets of the mosques Lashar and Akmer at Cairo, which in some parts have perforated battlements of fanciful outline rising above the general parapet of open-work. Curves, forming pointed horse-shoe arches, occur in some of the patterns; further than this it is impossible to pretend to describe them, except it be to remark that the stone-work is very slender, and the open spaces large in proportion, and that the ribs or stems of which the former is composed have something the resemblance of being interwoven, one passing alternately before and behind the next, after the fashion of wickerwork.

Equal fancy and diversity of invention are shown in the devices of mosaics and pavements, many of which appear exceedingly elaborate, although, when analysed, they are found to be very simple in principle: for instance, some patterns exhibiting octagons, stars, and other figures, are produced merely by series of zigzag lines intersecting each other at right angles, different combinations being obtained according as the points of the zigzag are turned from or towards each other. Among the other ornaments which mark this style, the honeycomb fretwork and stalactite-like drops, or pendents of ceilings and roofs, deserve to be mentioned: of these, the rich example in the Alhambra Court, a copy in full size of the stalactite roof of the Hall of the Abencerrages, but coloured and gilt in accordance with what Mr. Jones conceives to have been the appearance of the hall in its original state, will at once recur to the memory. Another characteristic form of ornament is that of the small star-shaped apertures cut in a sloping direction through the domes or vaults over baths, &c., for the purpose of admitting only a subdued degree of light.

The above are characteristic elements of the style generally. But there are others equally characteristic of the Asiatic varieties, though not found in the Spanish. Of these, a constructive feature, as striking as the arch itself, is that of the *dome*. For the most part domes occur in mosques and other religious edifices, but they are also usual in tombs. Domes were derived directly from Byzantine examples, and were therefore pendentive in character; but following the Oriental tendency to inflation and luxuriance, they were variously altered in size, application, and ornamentation, and ultimately in Persia, Turkey, and still more extravagantly in India [INDIA, ARCHITECTURE OF, col. 848] assumed a bulbous form, thus losing sight of the mathematical principles which render the dome so constructively simple an architectural feature. [DOME.] Moreover, instead of being employed singly, domes were sometimes used in great profusion, there being, besides the principal dome, a number of subordinate ones, sometimes according and at others contrasting with it in shape. *Minarets* are another characteristic feature in the Asiatic varieties of Saracenic architecture; but for an account of them it will be enough to refer to the article MINARET. The long and slender forms of minarets being opposed to the swelling curves of domes, contributed not a little to that picturesqueness of outline which is so striking in buildings of later Saracenic style. The cut of the At-Meidan at Constantinople, given under MOSQUE, will serve as an illustration of the multiplication of domes and the application of the minaret, whilst the article itself will furnish some general information on the subject of mosques.



Mosque (Cathedral) at Cordova.

We may now briefly notice a few of the more characteristic existing examples of the style; beginning with those of Spain. Of these the oldest is the mosque at Cordova, which now serves as the cathedral of that city. It was the earliest structure of any importance erected by the Moors in Spain, having been commenced by the Caliph Abd-el-Ramhan, in 786 A.D., with the avowed intention that it should surpass in splendour the mosques of Baghdad, Damascus, and Jerusalem. It was completed in 796. Like all early Saracenic work it is characterised by a certain severity and massiveness of style. Byzantine architects are said to have been specially invited into Spain to superintend its construction. In its plan the original building bore a general resemblance to a basilica, but it was greatly altered about the close of the 10th century by El Mansour, who converted it into a parallelogram by adding eight aisles to the eastern side. As it now stands it is an insulated oblong building, extending 620 feet from north to south, including a spacious court at its north end or side. The interior presents almost a forest of jasper and other marble columns, upwards of 600 in number, and dividing the plan into nineteen aisles in one direction (350 feet in length), and thirty-five in the other. But it is disproportionately low as compared with its great extent, the height to the roofs being only about 34 feet. The arches are carried upon columns without entablatures as in Romanesque buildings. [ROMANESQUE ARCHITECTURE.] The interior presents a singular array of double, circular, and horseshoe arches, some of the upper ones being curiously interlaced. There is a great display of rich carving of a modified Byzantine character, and much of the peculiar tracery and diapering, as well as numerous inscriptions of the kind described above. The pointed arch does not occur; the domes are comparatively recent additions. In that division of the building appropriated to the imams and chiefs was the great *kibla*, or sanctuary (in which the Koran was deposited), an octagon covered with a cupola shaped out of a single block of stone; the *mihrab*, or pulpit, and the *maksura*, or khalif's seat. After the conquest of the city in 1236, by San Ferdinand, this mosque was converted into the cathedral, in consequence of which the character of the interior has been greatly injured by the erection of a Gothic choir in its centre. As a splendid work of a later epoch of the style, Cordova could once boast of the palace called the Az-zahrá, erected about the middle of the 10th century by the celebrated Abd-el-Rhaman III., the eighth Umeyyah sovereign of Spain. Of this edifice, which was at the distance of about two leagues from the city, nothing now remains to attest its former magnificence, except the descriptions given of it by Mohammedan writers, according to which it was adorned with 4000 marble pillars, and had walls and pavements of the same material. The sumptuousness ascribed to the edifice and its fountains and baths might pass for mere Oriental hyperbolism, were it not that the evidence still afforded by the Alhambra, and by parts of the Alcazar at Seville, removes the suspicion of exaggeration; or rather, the exuberant beauties revealed to us by the latter structures greatly surpass anything the most florid description can picture to the mind.

The Alhambra, the residence of the Moorish kings of Granada, is supposed by some to have been founded by Mohammed Ibn Alhamar, the first ruler, who reigned from 1238 to 1273; according to others, was begun by his successor Mohammed II. (1273–1302), or by Nasser, and completed by Abu-l-hejaj in 1348. This highly interesting and important monument of western Arabian architecture is now rendered comparatively familiar to us, by descriptions and drawings, and by geometrical and pictorial illustrations of its principal parts and decorations, not only in the elaborate works of Murphy, Jones, and Hassemer, but also in many drawings and publications of a more popular kind by Roberts, Lewis, and other able draftsmen, while several parts of the interior have been reproduced by casts and restorations in the Crystal Palace at Sydenham. Here therefore it need only be noticed briefly and generally: it is described, with cuts, under ALHAMBRA, in the GEOG. DIV.

The Alhambra was a fortress palace, the outer-walls of which enclosed an area 2500 feet long and 650 wide. Its superb palace has suffered alike from wilful destruction and from neglect, yet its ruins are among the most romantic and most interesting in the world. What is left of it consists of two great courts or halls and several of smaller size. Of these the richest and most impressive is the Court of the Lions, which extends 100 feet from east to west, and is 60 feet wide: yet impressive as it still is, and gorgeous as it must have originally appeared, it is really composed of only the most seemingly fragile materials—wood covered with stucco. Its general character and appearance will be best understood by the reproduction at the Crystal Palace; but it must be remembered in looking at the copy that whilst the original is of much larger size, the central fountain, from which it derives its name, is, in each, of the same dimensions. On each side of the Court of the Lions is a much smaller apartment, that on the north being known as the Hall of the Sisters, while on the south is the gorgeous Hall of the Abencerrages, reproduced of the actual dimensions by Mr. Jones at the Crystal Palace. At the east end stands the Hall of Judgment. Before the Hall of the Two Sisters are the Baths. West of the Court of the Lions, and at right angles to it, is the second great court, called the Court of the Alberca—an older and less ornamented building. There are other connected rooms and detached buildings to which it is sufficient to allude, while a third large court, probably a mosque, is said to have been removed to make room for the cold and formal palace erected by Charles V. adjoining the Court of the Alberca. The architectural character of the interior, on which almost exclusively the florid ornament is lavished, has been already spoken of, and the arches, pillars, tracery, diapering, &c., described. The Alhambra is considered, and justly, as the crowning work of Saracenic architecture in Europe; it marks a period when the style had reached the very verge of decorative propriety, and it is probable that any further progress would have been towards mere voluptuous excess, and that the decline would have been swift and certain. Other remains of Saracenic buildings are still numerous in all those parts of Spain which were occupied by the Moors, and some of them are of considerable interest. It is noteworthy, however, that the only approximation to a minaret, or to any of those light and lofty forms in which the Saracenic architects of the East delighted, is found in the Giralda at Seville; and this bears more resemblance to an Italian campanile, it being a square of 45 feet, and rising undiminished to a height of 185 feet: the upper and smaller portion was added in 1568.

The earliest of the Egyptian buildings of which any portions remain is the Mosque of Amrou at Old Cairo, begun about A.D. 642, but greatly altered, if not rebuilt, about 60 years later. It is a nearly square building about 390 by 360 feet, surrounded on each side by colonnades or arcades, the columns of which, 245 in number, were taken from Byzantine and Roman buildings. The arches, as is usual in arcades in the Saracenic buildings of the East, have tie-beams, in this instance of wood. Of the original ornamentation little is left. A more important example of the style is the great mosque erected by Ibn Tooloon at Cairo, towards the end of the 9th century, and which is still in a state of tolerable preservation. Like the preceding, it is a nearly square structure, the outer walls being 455 feet by 390; the great court, nearly 300 feet square, is said to have been designed by a Byzantine architect. Like all early Mohammedan buildings, it is built entirely of brick covered with stucco, and all the rich interior ornamentation is of stucco. The arches of the colonnade surrounding the great court are of the pointed horse-shoe form, and are borne on massive piers with attached shafts at the angles. The windows, mostly of pointed horse-shoe arches, are all filled with the pierced tracery described above, which is not only singularly graceful in design, but the effect of which is described as exceedingly cool and pleasing in such a climate. Other mosques in Cairo afford very interesting specimens of this style of architecture of a later date; as that of Barkook, erected about the middle of the 12th century, which has a fine dome, a lofty and very elegant minaret, and other ornamental features, and in which the pointed arch is employed with as much facility as in a Gothic cathedral. But a far more imposing building is the mosque of Hhasaneyn, or Hassan, which is of great size and height, very massive in construction, and is crowned by a noble dome and two very handsome minarets, each 280 feet high. The mosque of El Moyed, erected in 1415, is remarkable for the richness of its interior.

For the fall of the Moorish dynasty in Spain, the Mohammedans were to a certain extent recompensed by the conquest of the great Christian city and territory of Byzantium; and from that time dates a new variety of Saracenic architecture which had its origin in Constantinople. On the capture of Constantinople, Santa Sophia was converted by the conquerors into their chief mosque, and made their architectural model. The older Saracenic style indeed continued to be the basis of the new, but it was modified throughout by the Byzantine influence. The dome became a more and more prominent feature; ornamentation was applied with more economy, more grouped and massed, more simplified and less diffused. But the old Eastern exuberance found vent in various ways, while the taste and energy which served at once to direct and control it, became less and less apparent, and the style steadily deteriorated, though as long as vitality lasted, it exhibited gleams of a rich quaint fancy. The first mosque erected in Constantinople was built by Mahomet II., the conqueror of the city; and a large mosque is still shown as his; but very little remains of the original fabric. More perfect is the great mosque erected about the middle of the 16th century by Suleiman the Magnificent. Avowedly an imitation of Santa Sophia, it is yet larger, richer, and to an architectural eye, superior in form, the dome especially being higher and better proportioned. The great mosque, called At-Meidan, erected by Achmet in the first half of the 17th century, is remarkable among other things for its array of cupolas and its minarets. No less than thirty small domes surround the outer court, each bay of the arcade being surmounted by one. The mosque proper has a well-proportioned great dome (80 feet in diameter), flanked by four smaller domes, while (as will be seen from the cut in the article MOSQUE), several other small domes occur in different parts of the building. In this, as in the other Constantinopolitan mosques, the columns which support the horse-shoe arches of the arcades are fastened together by iron tie-rods. The great dome of this mosque is borne on four immense piers, which are faced with marble. The minarets are of very graceful form and proportions. The various ornamental details are pure in character, whilst they, as well as the general form of the building, show almost entire freedom from Byzantine taste. But this was the last great effort of Turkish architecture. European artificers soon after this began to be employed, and European fashions to be imitated, and the native style became proportionally debased.

SARACENS, a name improperly given by the Christian authors of the middle ages to the Mohammedans who invaded France and settled in Sicily. Concerning the etymology of this word there have been various opinions. Du Cange ('Glossarium,' *v.* 'Saraceni') derives it from "Sarah," the wife of Abraham; Hottinger ('Bib. Or.') from the Arabic word *saraca*, which means "to steal, to plunder." Forster, in his 'Journey from Bengal to England,' derives it from *sahra*, "a desert." But the true derivation of the word is *sharkeyn*, which means in Arabic "the Eastern people"—first corrupted into Saraceni (Σαρακηνοί) by the Greek, and thence into *Saraceni* by the Latin writers. Stephanus Byzantinus says that "Saraka is a region of Arabia, adjoining the Nabathæi, and the inhabitants are called 'Saraceni.'" Ptolemy (vi. 7) makes Saraka a city of Arabia Felix. The name Saraceni occurs in Pliny (vi. 28), and it seems that it began to be used about the 1st century of our era, and was applied to the Bedouin Arabs who inhabited the countries between the Euphrates and the Tigris, and separated the Roman possessions in Asia from the dominions of the Parthian kings. The description of the Saraceni by

Ammianus Marcellinus (xiv. c. 10) exactly corresponds with the habits of the Bedouins. In course of time it became the generic name of all the Arabian tribes who embraced the religion of Mohammed, and spread their conquests over the greater portion of Asia and Africa.

SARCOCELE (from σάρξ, flesh, and κήλη, a tumour) is the name of a disease by which the testicle becomes altered from its natural structure and converted into a hard flesh-like substance. The term however is of such general import, that there are few diseases of the testicle which may not be included under it; accordingly the older writers called all indurations and enlargements of this organ sarcoceles, whether they were of a benign or of a malignant nature. In modern phraseology the term is restricted to certain chronic enlargements and indurations of the body of the testis, of a perfectly benignant character, but inconvenient on account of their size and weight. These swellings may continue for years without undergoing any visible change, or a sudden increase in their bulk may arise, and the testicle be converted into a painful, ulcerated, and incurable mass of disease. Sarcocele may be distinguished from hydrocele, the disease which most nearly resembles it, by its hardness, weight, and want of transparency; but occasionally the two diseases are met with together, and this compound affection is called hydrosarcocele. With respect to the treatment of sarcocele, various and rather opposite remedies have at times proved successful. When the enlargement is accompanied by pain or any degree of inflammation, leeches, hot fomentations, and poultices applied externally, with the administration of an emetic, and the adoption of a general antiphlogistic regimen, would seem to be indicated. When the disease is altogether chronic, stimulating lotions, liniments, or ointments may be applied to the swelling. In either case, the use of a suspensory bandage, or bag truss for the support of the part should not be neglected. If these means fail in arresting the progress of the disease, extirpation of the gland must be had recourse to.

SARCOCOLLIN ($C_{22}H_{19}O_{10}$?). A gummy matter, extracted from the sarcocolla of commerce, the dried juice of the *Penea mucronata*. It possesses a peculiar but feeble odour, and a bitter-sweet taste. It is sparingly soluble in water, but readily so in alcohol. Nitric acid transforms it into oxalic acid.

SARCOMA is a morbid tumour whose tissue is fleshy and moderately firm. Several species of sarcoma were described by Mr. Abernethy in his 'Classification of Tumours,' such as the common vascular sarcoma, the adipose or fatty kind, the pancreatic, the mammary, &c. Some of these still retain the same names, but in general the term sarcoma has no other meaning in surgical works than the indefinite one already given, and includes all fleshy tumours that are not cancerous, or medullary, or melanotic. [TUMOUR.]

SARCOPHAGUS, a word derived from the Greek signifying *flesh-eater*, but used to designate any kind of coffin, especially large ones of stone. This name was given from sarcophagi being originally made of a kind of stone from Assos in Mysia, supposed to be *alumens chisti*, or a kind of pumice stone, which was fabled to consume the entire body, with the exception of the teeth, in the space of forty days. (Pliny, 'N. H.,' ii., 98, xxvi. 27.) The term was, however, applied at the time of the Roman Empire to all kinds of stone coffins. (Juvenal, x., 172; Dig., 34, tit. i., s. 18, s. 5; 'Orellius Inscript.,' Nos. 194, 4452, 54.) The earliest sarcophagi are the Egyptian, called in the hieroglyphs *teba*, or chest, and found from the time of the pyramids [PYRAMIDS] till the 1st century A.D. Those of the early dynasties were sculptured in shape of a square chest, or edifice, and left plain or else only ornamented with two leaves of the lotus. Those of the 18th and following dynasties were of different shapes, the most usual being that of an Egyptian mummy swathed, dividing into two parts lengthwise, the cover formed by the front, and the chest by the back of the figure—the two fixing by mortices and grooves, holes for which were cut in the stone. The coffins of this period were principally of red granite, and ornamented with inscriptions or scenes relating to the myth of Osiris, or the passage of the Sun through the lower hemisphere, or regions of the night and darkness. The most remarkable of this period are the arragonite or oriental alabaster sarcophagus of Seti I., in the Soane Museum, and that of Rameses III., in the Louvre, the cover of which is in the Fitzwilliam Museum at Cambridge. At the period of the 26th dynasty, the sarcophagi were generally made of basalt; although a coarse red granite, black or white marble was occasionally used. The hieroglyphic legends of this age are often chapters extracted from the Ritual of the Dead. The last of the royal sarcophagi is that of Nekhtherhebi, or Nectanebes I., in the British Museum, made of a fine breccia, and sculptured with scenes of the passage of the Sun. This was formerly at Alexandria, and supposed upon very insufficient grounds by some to have been the tomb of Alexander the Great. Recent discoveries have shown that the Phœnician kings were buried in sarcophagi of basalt or alabaster, of a mummied shape like the Egyptians, although different in treatment and art. The most remarkable of these is that of Esmunazar, king of Sidon, inscribed with a long Phœnician inscription, and supposed to be of about B.C. 574. The Persian monarchs were also buried in sarcophagi, and one of those of the kings of Judah, a plain rectangular chest, decorated with a simple floral ornament of vine branches, is in the Museum of the Louvre. Rude sarcophagi were also used by the Lycians and other Græco-barbaric people of Asia Minor.

In Asiatic and European Greece many sarcophagi have been found, but few, if any, earlier than the Roman Empire, and generally of the 1st and 2nd century A.D. These are of the same character as those discovered in the Roman columbaria, consisting of rectangular chests about 8 feet long, 3 feet high, and as many broad. The covers are often in shape of a pent roof, or ornamented with figures of the deceased in full relief. They are richly decorated with bas-reliefs, at an earlier period, of many figures representing mythological subjects, but at a later with festoons of flowers, fruit, and arabesques, with small figures. A still larger class than the Greek are the Etruscan, none of which, from their style of art, seem older than the middle of the 4th century B.C., and are made of peperino, alabaster, or terra-cotta, generally having on their covers a full-length recumbent figure of the deceased leaning on the elbow as if on a couch at a feast. The chests are decorated with reliefs, representing Greek myths, treated in the Etruscan manner, with the names of the persons represented in the Etruscan language. Those found in the tombs of Volterra and Chiusi are of arragonite or marble, of small dimensions, about 14 inches long by 3 inches broad, and 1 foot 6 inches high, and are rather cinerary urns, as they contain only the ashes of the dead. The Roman sarcophagi, at the time of the republic, appear to have been plain architectonic chests, as shown by those of the Scipio family, but under the empire they became more richly ornamented, like the Etruscan, with recumbent figures on the cover and bas-reliefs of mythological subjects, allusive to the life or death of the person buried, as Prometheus, Orestes, and Ganymede. These sarcophagi continued till the 6th and 7th century, when arabesques were introduced, and two remarkable ones of the first period of Christian art are those of St. Constantia and St. Helena of red porphyry, ornamented with bas-reliefs, representing triumphs and processions, at present in the Vatican. At a later period Christian sarcophagi are ornamented with subjects taken from the Old and New Testament. Stone chests or sarcophagi were also used for interment by the Gaulish tribes, and their use for the sepulture of distinguished persons has been continued till the present day.

(De Rougé, *Monuments Égyptiens du Musée de Louvre*, 8vo, Paris, 1855; Duc de Luynes, *Le Sarcophage d'Esmunazar*, 4to, Paris, 1856; Micali, *Storia d'Italia*, Fir., 1832.)

SARCOSINE ($C_6H_7NO_4$). An organic alkaloid, belonging to the same class of bodies as urea and sugar of gelatine. It is procured by adding hydrate of baryta to a boiling saturated solution of creatin. On filtration a colourless liquid is obtained, containing caustic baryta and sarcosine. Through this liquid a current of carbonic acid gas is passed whilst it is gradually heated to boiling. The filtered liquid becomes syrupy on evaporation, and finally deposits large crystalline leaves of sarcosine, which is purified by conversion into sulphate, agitation with alcohol, solution in water, and final treatment with carbonate of baryta. The filtered liquid being then evaporated upon the water-bath deposits crystals of pure sarcosine, which are colourless and transparent, very soluble in water, slightly so in alcohol, and insoluble in ether. They fuse at a temperature somewhat above 212°, and volatilise without residue.

Sarcosine is isomeric with lactamide, urethane, and alanine. It does not affect vegetable colours, but forms salts with acids. The sulphate of sarcosine has the formula $C_6H_7NO_4, SO_3HO + aq.$, that of the double platinum salt is $C_6H_7NO_4, HCl, PtCl_2 + 2\ aq.$ The solution of the sulphate reacts strongly acid.

SARDONICUS RISUS, a convulsive affection of the muscles of the face, in which the lips are drawn involuntarily apart, so as somewhat to resemble the expression of the countenance in laughter. The name is derived from a species of ranunculus that grows in Sardinia, called Herba Sardonica, or Sardoa, which is said to produce this affection in those who eat it.

Risus Sardonicus is observed as an effect of certain vegetable poisons, such as the *Ranunculus sceleratus* of Linnæus, but is more frequently met with as one of the symptoms of tetanus, or locked-jaw, or as an attendant on other convulsive affections.

The term is employed figuratively to denote that forced laugh by which persons sometimes endeavour to conceal their real feelings.

SAROS, NEROS, SOSOS. These names are from the fragments left of Berosus, who says that the Chaldæans had three astronomical periods so called, the saros of 3600 years, the neros of 600 years, and the sosos of 60 years. Of the two latter we know nothing more, and as to the saros, the duration given by Berosus is either entirely wrong, or else subsequent writers have taken another Chaldæan period, which is neither of the three above, and applied the term saros to it. Geminus (ch. 15) mentions that the Chaldæans had found a period of 669 months, or 19,756 days (so the text stands after an emendation by Bouillaud). Ptolemy mentions the same period, and Pliny (lib. ii., c. 13) remarks relative to it, that eclipses return again after a period of 223 (the third of 669) months; but the text here again was corrupt, until Halley ('Phil. Trans.,' No. 194) restored the true reading, which was afterwards confirmed by manuscripts. To complete the misfortunes of this period, Suidas has the word Saros, but it was omitted from his Lexicon either by mistake or faultiness of manuscripts, until Dr. Pearson restored it ('Exp. of the Creed,' 1683, fol. 59, according to Weidler), and even then it gives 222 months instead of 223, which was again corrected by Halley. In the time of Riccioli, Geminus and Ptolemy were the authorities cited on this period, and the name Saros was not applied to it. Many writers (Costard for example) confound it with the Metonic period of 235 lunations, which is a totally different thing: others again, as Geminus, and even Riccioli, appear to consider it as a period for the determination of the lunation or month; and perhaps the assertion made by some others, that the Chaldæans were in possession of the Metonic cycle, may be another confusion between the latter and the saros.

Leaving the authorities on the subject, we know [MOON] that 223 average intervals between full moon and full moon make up very nearly 242 nodical months, or passages of the moon from one node to the same again. Now since the eclipses entirely depend upon the manner in which the full and new moons take place relatively to the node, it is obvious that if 223 lunations were exactly 242 nodical months, and if the sun's and moon's orbits were truly circular, and their motions uniform, all the eclipses of one set of 223 lunations would be produced again precisely in the same order during the next 223; that is, if there were (say) an eclipse of the sun during the 47th lunation, reckoning from a given full moon, there would necessarily be another in the (47 + 223)rd, or the 270th lunation, and so on.

All these suppositions are near enough to the truth to make this sequence of eclipses very nearly take place. For since 223 lunations make 241·029 sidereal months, 238·992 anomalistic months, and 241·999 nodical months, it is obvious that at the end of a saros the moon is in the same position with respect to the sun, nearly in the same part of the heavens, nearly in the same part of her orbit, and very nearly indeed at the same distance from her node as at the beginning of the period. Now 223 lunations make 6585·32128 days, or 6585 days, 7 hours, 42 minutes, and 38 seconds; or 18 years (of 365 days), 15 days, 7 hours, 40 minutes, and 38 seconds. Consequently a saros of five leap years is 18 years, 10⅓ days, and one of four leap years is 18 years, 11⅓ days, nearly. The Chaldæan period is 6585⅓ days; and to avoid fractions they appear to have put together three such periods, making 19,756 days, and 669 lunations. From what has been said above, it might be inferred that the rotation of the moon's node is made in nearly a saros; and in fact that revolution does take 18·6 years.

It is to be observed, however, that the end of each saros is not in the same part of the day as the beginning, which is of consequence as to the solar eclipses, though not so as to the lunar, and still more does the inexactness of the period affect the former. For a saros contains 241·998659 mean nodical revolutions; so that if the moon be in her node at the beginning of a saros, she will want ·001341 of a revolution of being in her node at the end of it. This is about 29′, nearly the moon's diameter, which makes it sometimes happen that a lunar eclipse which takes place in a certain lunation of one saros does not take place in the same lunation of the next, and very often causes the same as to a solar eclipse. And the effect must be that at last the eclipse of any lunation is destroyed, by the accumulation of these errors of 29′ each time. Nor do the circumstances of one saros precisely resemble those of another until a longer period of about 746 such periods has elapsed. But in the same manner that eclipses are removed out of one lunation by the inexactness of the period, they are carried into another. There are about 70 eclipses in each saros, 30 lunar and 40 solar.

The Metonic cycle of 235 lunations gives 255·021 nodical months, which is not near enough to a whole number to produce anything like a return of similar eclipses. But it is, as explained [MOON], near enough to an exact number of years to restore the full moons to the same days of the year, or the preceding or following days. The Metonic cycle is a chronological period; that is, portions of time measured from a given epoch, and each equal to 19 years, are used in chronology. But the Saros is not a chronological period, but only a portion of time with any arbitrary commencement. Hence the student must not look in works on chronology for any information upon it.

SARSAPARILLA. [SMILAX.]

SASSAFRAS, *Medical properties of.* The tree which yields this substance is the *Sassafras officinale* (Nees) (*Laurus Sassafras*, Lin.); a native of North America, occurring from Canada to Florida. It is said to grow in Mexico, and Martius mentions it as a part of the Materia Medica of Brazil; but it is probable that it was introduced from Florida. Though Martius distinctly enumerates *Laurus Sassafras* (Linn.) among the medicinal plants of Brazil (Spix and Martius's 'Travels in Brazil,' English translation, London, 1824, vol. ii. p. 96); yet recent writers state the Brazil sassafras to be the produce of *Nectandra cymbarum* (Nees), the *Ocotea amara* of Martius. (Mart. in Buchner's 'Report,' xxxv. 180.) This point is worthy of careful determination, if Martius' statement be correct, that the bark of this tree is an ingredient in the famous woorary poison. Sassafras nuts are probably the produce of one or two species of *Nectandra*. The bebeerine, an important anti-febrile medicine, is the bark of *Nectandra Rodici* (Schomb.). It is a constituent, probably, along with quinia, of Warburg's fever drops. The root is the officinal part in the London Pharmacopœia; but the whole plant possesses the aromatic odour common to the *Laurineæ*, and some assert that the bark of the stem and branches is stronger than that of the root; but this seems to be an error. The root, invested with the bark, comes to Europe in pieces sometimes 2 feet long, and from the thickness of an arm to half a foot in diameter, irregularly bent, knotty, and with a light, soft, porous wood. The bark also occurs detached from the wood in pieces two or three inches long, from one and a half to two inches broad, sometimes rolled outwards, but more generally curved inwards; of a dirty grey or brownish colour externally, and a fungoid surface of a reddish colour internally. The taste is sharp, acrid, aromatic, and, as well as the odour, resembles fennel.

The chief constituents are: volatile oil, resin, and extractive. The oil is the most active. It may be obtained by distillation. Ten pounds of the root yield two and a half drachms. The specific gravity is 1·094. It consists of two oils, separable by water, in which the one floats and the other sinks. By time or a low temperature, it deposits a stearopten, or crystals of sassafras camphor.

Sassafras acts as a stimulant to the circulation, especially of the capillaries, causing an increased secretion from the skin, if the person be kept warm, or from the kidneys, if cool. Should these organs fail to be influenced by it, heat and general excitement, with headache, are the results. It is of unquestionable utility in gout and rheumatism, but its activity is generally destroyed by the improper mode of administering it. Decoction dissipates the volatile oil, and is a most objectionable preparation. Infusion or a tincture may be used, or the volatile oil rubbed up with sugar. Other species of Sassafras are used in India and Java. Sassafras tea is sold in the streets of London under the name of saloop.

SATELLITE (*satelles*, an attendant soldier or guard), a name given to the smaller planets which accompany and revolve round the larger ones. With this exception, that the rotation of a satellite round its own axis is made in the same time as its orbital revolution round its primary, in every case in which it has yet been fully made out that there is a motion of rotation, there seems to be no circumstance which can be pointed out in which the satellites have any distinctive peculiarities. The earth has one satellite [MOON], JUPITER has four, SATURN eight, URANUS six (according to William Herschel), though the existence of four only has yet been established, and NEPTUNE one. See also GRAVITATION, SOLAR SYSTEM, ASTRONOMY.

SATIN. [SILK.]

SATIRE is properly a species of Roman poetry, and must not be confounded with the Satyric drama of the Greeks. The Latin word *Satura* or *Satira* appears to have originally signified a collection of various things, and accordingly this name is applied to food composed of various ingredients, and also to a law consisting of several distinct particulars of a different nature. (Festus, s. v., Diomed. iii., p. 483, ed. Putsch.) The Roman satire is first mentioned as a kind of dramatic performance (Liv. vii., 2), and appears to have been, like the early Atellanæ Fabulæ, only a rude improvisatory farce, without dramatic connection, but full of raillery and wit. This species of composition arose from the practice, which has prevailed in Italy from the earliest times to the present day, of the country people making rude extempore verses in ridicule of one another at various festivals, and especially at the time of the vintage. Such were the Fescennini verses, which Macrobius tells us ('Saturn.,' ii., 4) were sometimes written as satires upon persons. The old dramatic Saturæ continued to be performed on the Roman stage till a late period, under the name of Exodia, which were laughable interludes in verse, and were performed between the different Atellane plays.

The name of satire was afterwards limited to a species of poetry peculiar to the Romans, in which Ennius is said to have been the first writer. The satires of Ennius appear to have been so called because they were written on a variety of subjects, and in many different metres; but as hardly any fragments have come down to us, we know very little of the subjects of which they were composed. Lucilius however was the first who constructed satire on those principles of art which were considered in the time of Horace as essential requisites in a satiric poem. Lucilius principally used the hexameter metre, which was afterwards almost exclusively employed by the satiric poets. His poems were not only satires upon the vices and follies of mankind in general, but also contained attacks upon private individuals. They formed the model on which Horace wrote his satires. His easy temper and happy disposition, as well as the principles of the Epicurean philosophy, led him to attack the foibles and follies of mankind in a style of playful raillery, which forms a striking contrast to the severe invectives of Juvenal. The increased corruption of morals at Rome under the early emperors, and the cruel punishments which had been inflicted by Domitian upon the wise and the good, naturally led Juvenal to attack the vices of his age with severity and vigour. The works of the other Roman satirists are lost, with the exception of Persius and a few verses on the banishment of the philosophers by Domitian, which are ascribed to Sulpicia, who is supposed by some writers to be a contemporary of Tibullus, and by others of Ausonius.

SATISFACTION (in Law), is said to exist where a party, having a right of action, accepts from the party against whom he has it, a certain and valuable thing, or the performance of a certain and beneficial act, in lieu of his right of action. If the action is afterwards brought, the satisfaction may be pleaded in bar of it. Satisfaction may exist as to actions in which damages are recoverable, and as to some others; but it cannot operate so as to dispense with the performance of a covenant under a deed, as a deed can only be made void by an instrument of the same nature. Where, however, a right of action upon the deed has vested, as in the case of a breach of covenant to repair, to pay rent, &c., there may be satisfaction. The satisfaction, to be valid, must have been accepted by the party who has the right, and must have proceeded from the party who is liable.

Nothing which is paid or done to a third party, or proceeds from him, can operate as a satisfaction. It must also be certain, that is, definite as to time, &c., and available; thus where the satisfaction is by mutual agreement, it must be such an agreement as an action may be maintained upon. It must be valuable; by which it is understood not only that there can be no satisfaction consequent of a thing which has no value, as, for instance, a rush; but also that the value must be at least not obviously inferior in amount to that for which it is given, such as a payment of a less sum of money at the same or a subsequent day as that on which a greater is due. Although if there are advantageous circumstances attendant on the payment of a less sum, this may operate as satisfaction. But the giving of a horse or a statue may be a satisfaction of a claim for a sum of money, if accepted as such, though the horse or statue be in reality of less value than the money.

A negociable instrument may operate as a satisfaction of a debt; and if the party who accepts it, by his own negligence fail to recover upon it, the debtor will nevertheless continue discharged. The performance must be actually executed; a mere endeavour, or a readiness to perform, such as a tender of money, or a part performance, cannot operate as a satisfaction. It must be beneficial; thus where one has made a forcible entry on the lands of another, it is not a satisfaction for the wrongful entry to permit that other to re-enter. In an action for trespass and taking cattle, a mere re-delivery of the cattle is not a satisfaction, though their conveyance to another place, and redelivery there, may be so. The benefit also must be one partaking in some shape of a pecuniary character. It must either be money, or capable of being measured by money. Thus a submission before certain persons made in pursuance of the order of a court-martial, or an acknowledgement of the injury and prayer for forgiveness kneeling, though a satisfaction in honour, is not such satisfaction as to deprive the party of his right to damages. Satisfaction to one of several plaintiffs is a bar to all: and satisfaction by one joint wrongdoer discharges the others. (Com., 'Dig.,' tit. 'Accord.')

SATRAP (σατράπης) was the name given to the governor of a province of the Persian empire. He was appointed by the king, and was responsible alone to him. Such a system of government has always existed in the large Asiatic empires; but the advantage which the Persian system had over many others of a similar kind, was the careful separation made between the civil and military powers. The governors of the garrisons and the commanders of the troops were independent of the satraps, and responsible only to the king. The duties of the satraps are briefly defined by Xenophon to consist in governing the inhabitants, receiving the tributes, paying the garrisons, and attending to whatever else is necessary. ('Cyrop.,' viii. 6, § 1-3.) In the later times of the Persian empire, it became the custom to appoint the satraps to the command of the troops also, especially if they were members of the royal family. In this manner the younger Cyrus was appointed satrap of one of the western provinces of Asia Minor, and at the same time general of all the forces which assembled in the plain of Castolus. (Xen., 'Anab.,' i. 1, § 2.) The practice of uniting the civil and military powers in one person, and the greatness of the command entrusted in some cases, was also dangerous to the royal power. An instance of this kind occurs as early as the time of the first Darius, in the case of Orœtes, who was governor of Phrygia, Lydia, and Ionia, and was so powerful that Darius dared not proceed openly against him. (Herod., iii. 127.) Subsequently this practice became still more frequent; Cyrus had the command of the greater part of the western provinces of Asia Minor; and after his death, Tissaphernes was allowed to hold them in addition to his own. From this period we frequently read of revolts of the satraps, and many of them became quite independent of the king of Persia. (Heeren's 'Asiatic Nations,' vol. i.)

SATURATION, a term applied in chemistry to denote two widely different phenomena: namely, first to the solution of the greatest possible quantity of any substance in a liquid medium; and, secondly, to the neutralisation of a base by an acid or of an acid by a base.

When common salt, and indeed most other saline and many vegetable bodies, are added to water until it ceases to dissolve them, the solution so obtained is termed a saturated solution of the substance dissolved.

Saturation of this kind may exist with regard to one body and not to another; thus water saturated with common salt will still dissolve sulphate of soda, and *vice versâ*; so also a saturated solution of common salt will dissolve sugar. The saturating power of bodies is in many cases greatly influenced by heat, while in others variations of temperature produce but little effect: thus cold water will take up nearly as much common salt as hot water; but sulphate of soda is more soluble in hot water than in cold, and hence it is that a saturated hot solution of this and many other salts deposits crystals on cooling. Cold water, on the contrary, dissolves more lime than hot, and a saturated solution prepared with water at about 32° holds nearly twice as much lime in solution as one prepared at 212°, and when the cold prepared solution is heated lime is deposited. This, however, is a case of much rarer occurrence than the contrary one.

As instances of the second kind of saturation, the following may be adduced:—If to a solution of carbonate of potash any strong acid, such as the sulphuric, be added until effervescence ceases, the potash is said to be saturated. In like manner, if a solution of caustic soda be added to nitric acid until the latter be exactly neutralised, the acid is said to be saturated. In these cases the point of saturation is determined by the use of papers stained with different vegetable colours; if, for example, too much carbonate of potash should have been added to the nitric acid to saturate it, its presence will be indicated by turning paper coloured yellow with turmeric, brown; while, on the other hand, excess of acids is in general ascertained by paper stained blue with litmus, which is rendered red by the action of acids.

By these means a very important process in the manufacture of soap and glass is conducted; it is termed *alkalimetry*, and employed for ascertaining the strength of different samples of the carbonates of potash and soda, so largely used in glass- and soap-making. Sulphuric acid diluted to a known extent is added to the alkaline solutions, and when they affect neither blue nor yellow paper, the saturation is perfect, and the purity and strength of the alkalies are determined. [ALKALIMETRY.]

SATURDAY. [WEEK.]

SATURN. The name of one of the old planets, the largest of all the bodies of the solar system, except the Sun and Jupiter. It is encompassed by three rings, unconnected with the planet, but revolving around it. It is also accompanied by eight satellites.

The apparent semi-diameter of Saturn, at the mean distance of the planet from the earth, is about 16″·4. The real diameter, that of the earth being represented by unity, is about 79,000 miles. The mean density is about 0·55 of that of the Sun, or $\frac{1}{7}$th of that of the Earth, and the mass of the planet is about $\frac{1}{3512}$, the Sun's mass being represented by unity. It revolves on its axis in 10 hours, 29 minutes; its equator is inclined to the ecliptic at an angle of 31° 19′. Its light and heat are to the light and heat received by the earth as 11 to 1000. The following are the elements of its orbit:—

Epoch 1801, January 1, 12th hour, mean astronomical time at Greenwich. Semi-axis major, 9·5387861, that of the Earth being represented by unity.

Excentricity, ·0561505; its secular diminution (diminution in 100 years) ·000,312,402.

Inclination of the orbit to the ecliptic, 2° 29′ 35″·7; its secular diminution, 15″·5.

Longitudes from the mean equinox of the epoch: (1) of the ascending node, 111° 56′ 37″·4; its secular increase (combined with the precession), 3070″; (2) of the perihelion, 89° 9′ 29″·8; its secular increase (combined with the precession) 6950″; (3) of the planet (mean), 135° 20′ 6″·5.

Mean sidereal revolution in 365¼ days, 43996″·13; sidereal revolution, 10759·2198174 mean solar days.

The discovery of the ellipticity of Saturn is due to Sir William Herschel, who concluded, from his observations, that the polar is to the equatorial diameter as 10 to 11. On a subsequent occasion he was led to suspect an irregularity in the figure of the planet, but the researches of Bessel, and also those of Mr. Main,* late first assistant at the Royal Observatory, Greenwich, have proved beyond all doubt that the form of the planet is strictly spheroidal.

When viewed in the telescope the planet Saturn appears to be diversified with belts extending across his disc in a direction parallel to his equator. It was by watching the changes in the appearance of these belts, that Sir William Herschel succeeded in discovering the motion of the planet on his axis, and in determining the time of a complete rotation.

The satellite of Saturn which was first perceived is the sixth in the order of distance from the primary. Its discovery was effected by Huyghens in 1655. Four other satellites were subsequently discovered by Cassini in the same century. These five satellites were named the first, second, third, fourth, and fifth, reckoning according to their distance from the primary. In 1789, two additional satellites were discovered by Sir William Herschel. Both of these satellites were found to revolve within the orbit of the *first* of the five satellites previously discovered. They ought therefore in accordance with the prevailing nomenclature, to be designated as the first and second satellites, but this would have rendered a revision of the names of the earlier satellites indispensable. The Herschelian satellites however were usually styled the sixth and seventh, reckoning *inward* in the order of distance from the primary. To remedy the imperfection which thus arose from confounding the order of discovery with the order of distance, Sir John Herschel has recently proposed to apply to the satellites the names of the Titanian divinities,—Japetus, Titan, Rhea, Dione, Tethys, Enceladus, Mimas, commencing with the most distant satellite. This nomenclature has been generally adopted by astronomers.

On the 19th of September, 1848, an eighth satellite of Saturn was discovered by Mr. Bond, at the Observatory of Harvard College, Cambridge, U.S.; and also independently, on the same evening, by Mr. Lassell at his Observatory near Liverpool. In conformity with Sir John Herschel's nomenclature it has been called Hyperion. It ranks the seventh in the order of distance from the central body. The following table will be found useful :—

---

* Now director of the Radcliffe Observatory, Oxford.

Name of Satellite.	Order of Distance from the Planet reckoning outward.	Period.	Mean Distance from the Planet in terms of the Planet's Radius.	Date of Discovery.	Discoverer.
		d. h. m. s.			
Mimas . .	1	0 22 37 22·9	3·3607	1789	W. Herschel.
Enceladus . .	2	1 8 53 6·7	4·3125	1789	W. Herschel.
Tethys . .	3	1 21 18 25·7	5·3396	1684	Cassini.
Dione . . .	4	2 17 41 8·9	6·8398	1684	Cassini.
Rhea . .	5	4 12 25 10·8	9·5528	1672	Cassini.
Titan . . .	6	15 22 41 25·2	22·1450	1655	Huyghens.
Hyperion . .	7	22 12?	28 ±	1848	Bond and Lassell.
Japetus . .	8	79 7 53 40·4	64·3590	1671	Cassini.

The periods and mean distances inserted in the foregoing table have been taken from Sir John Herschel's 'Outlines of Astronomy.' The period and mean distance of Hyperion have not yet been determined with sufficient precision.

The light of Japetus has been found to be subject to a variation depending on the position of the satellite in its orbit. From this circumstance it has been inferred, with a strong degree of probability, that the satellite effects a complete rotation on its axis in the same time as that in which it revolves around its primary, as in the case of the moon revolving around the earth. By far the most considerable of the satellites is Titan, which Sir John Herschel considers may be equal in magnitude to the planet Mars.

The appearance which Saturn presented to Galileo, when he first turned his telescope on the planet, was utterly inexplicable. The illustrious philosopher remarked, that the planet seemed to consist not of one but of three bodies, which almost touched each other and always maintained the same relative position. The three bodies were arranged in the same straight line, the largest body being in the centre, and the two others on the east and west sides of it. Pursuing his observations he found that the two lateral bodies continued gradually to diminish, until at length, after the lapse of about two years, they entirely vanished, leaving the planet quite round. He now felt much alarmed, lest those who derided his discoveries as optical illusions having no real existence, should adduce this mysterious transformation of the planet in support of their views. Writing to Welser on December 4, 1612, he says, "What is to be said concerning so strange a metamorphosis? Are the two lesser stars consumed after the manner of the solar spots? Have they vanished and suddenly fled? Has Saturn perhaps devoured his own children? Or were the appearances indeed illusion or fraud, with which the glasses have so long deceived me, as well as many others to whom I have showed them? Now, perhaps, is the time come to revive the well nigh withered hopes of those who, guided by more profound contemplations, have discovered the fallacy of the new observations, and demonstrated the utter impossibility of their existence. I do not know what to say in a case so surprising, so unlooked-for, and so novel. The shortness of the time, the unexpected nature of the event, the weakness of my understanding, and the fear of being mistaken, have greatly confounded me."

It was reserved for Huyghens to ascertain the real nature of the appendage with which Saturn is furnished. He originally announced his discovery in the form of an enigma, in a pamphlet entitled 'De Saturni Luna Observatio Nova,' published in 1656. The logogriphe ran thus :—

aaaaaaa ccccc d eeeee g h iiiiiii llll mm nnnnnnnnn
oooo pp q rr s tttt uuuuu.

In 1659 he published a work entitled 'Systema Saturnium,' in which he reveals the real nature of his discovery, and gives a detailed explanation of the various circumstances connected with it. Restoring the letters of the logogriphe to their original places, they now stood thus :—

Annulo cingitur tenui plano, nusquam cohærente, ad eclipticam inclinato ;

or, as thus translated :—

The planet is encompassed by a slender flat ring, everywhere unconnected with its surface, and inclined to the ecliptic.

Nothing can be more convincing or beautiful than the explanation which this theory affords of the various phenomena presented by the planet. When the position of the planet in its orbit is such that the plane of the ring passes through the sun, the edge only of the ring is exposed to the solar rays, and the extent of the illuminated surface being very small, it is incapable of producing a sensible impression on the visual organ. In this position, then, the ring is invisible, and the planet presents a round appearance like the sun or the full moon. The ring also disappears when its plane passes through the earth; for although one of its sides may then be illuminated by the sun, it is only the edge which is turned towards the observer. Besides these two causes of disappearance, which are of a transient nature, and render the ring invisible only for a few days at most, there is a third cause, which generally continues in operation during a longer period of time, and produces a more lasting effect. When the planet is so situated that the plane of the ring passes between the earth and the sun, the unenlightened side of the ring is then turned towards the earth, and consequently during the whole time that the planet is in this position (which frequently extends to several months) the ring will be invisible. The same theory affords an equally satisfactory account of the different phases assumed by the appendages of the planet during the period of its visibility. It is manifest that when the plane of the ring passes through the sun, and when consequently the ring ceases to be visible, the planet, if viewed from the sun, would appear in the node of the ring. When the planet revolves from this position, the sun commences to ascend above the plane of the ring, and the latter in consequence becomes visible in the form of a very elongated ellipse, gradually opening out in breadth. The ellipse continues to approach towards a circular form until the planet has reached a distance of 90° from the node of the ring, when the elevation of the sun above the plane of the ring has attained its maximum. The ring henceforth begins to contract, and the same succession of appearances in a reverse order will obviously ensue as the planet revolves towards the opposite node, where the ring again will cease to be visible. The ring will therefore complete the cycle of its phases in a period equal to half a revolution of the planet, or in about fifteen years. The appearances will not be materially different whether the ring be viewed from the earth or the sun, except during the time that the planet is in the vicinity of either of the nodes of the ring. At such a juncture, the combined motions of the earth and the planet may cause the plane of the ring to pass more than once through the earth, and the ring may in consequence disappear and reappear twice before its plane has entirely swept over the terrestrial orbit.

Huyghens was originally under the impression that the plane of the ring is parallel to the equator, and he consequently supposed its inclination to the ecliptic to be 23° 30′. On a subsequent occasion, however, he determined the inclination by actual measurement in conjunction with Picard and he found it to amount to 31°. Huyghens also fixed the ascending node of the ring in 170° 30′ of longitude. Several succeeding astronomers determined the elements of the ring. The most recent as well as the most complete investigation of the subject is due to Bessel. The conclusion at which he arrived was that in the beginning of the year 1800 the longitude of the ascending node of the ring was 166° 53′ 8″·9 and that the inclination of its plane to the ecliptic was 28° 10′ 44″·7. He also found that the node of the ring retreats upon the plane of the ecliptic at the rate of 46″·462 annually.

In 1675 Cassini found that the ring around Saturn consists in reality of two distinct rings separated from each other by a dark interval. This interesting fact was subsequently established beyond doubt by Sir William Herschel. The following are the dimensions of the planet and the two rings as assigned by M. Struve :—

Exterior diameter of the exterior ring . . .	40″·095
Inner diameter of the exterior ring	35″·289
Exterior diameter of the interior ring . . .	34″·475
Interior diameter of the interior ring . . .	26″·668
Equatorial diameter of Saturn	17″·991
Breadth of the exterior ring	2″·403
Breadth of the division between the rings . .	0″·408
Breadth of the interior ring	3″·903
Distance of the interior ring from the ball . .	4″·339
Equatorial radius of Saturn	8″·995

These measures are supposed to refer to the mean distance of the planet from the sun. At such a distance an object which would subtend an angle of only 1″ would measure 4387 miles. This would give 78,927 miles for the diameter of the planet. The absolute dimensions of the rings will of course bear a similar proportion to their respective angular measures. Thus, it will be found that the diameter of the exterior ring amounts to 175,928 miles.

The thickness of the rings around Saturn would seem to be very inconsiderable. This is plainly indicated by the circumstance that when the edge of the ring is turned towards the observer, it is generally found to be invisible, even when the most powerful telescopes are directed towards it. From certain lucid protuberances which Sir William Herschel remarked upon the ring, he was led to suspect that it had a rotary motion around the planet. A closer scrutiny of the phenomenon confirmed this impression, and he finally concluded that the ring effects a complete rotation around the planet in a period of 10h. 32m. 15s·4.

On the 15th of November, 1850, Mr. Bond, Director of Harvard College Observatory, Cambridge, U.S., discovered a third ring around Saturn, situated between the interior of the two rings already discovered, and the body of the planet. The same phenomenon was discovered by Mr. Dawes on the 19th of the same month, and, of course, before intelligence of Mr. Bond's discovery had reached England. The new ring is much fainter than either of the two exterior rings. Its breadth is equal to about two-fifths of the interval between the interior bright ring and the planet.

It turned out, soon after the discovery of the faint ring by Bond and Dawes, that the phenomenon had been also seen by Dr. Galle at the Berlin Observatory in the year 1838; but its exact nature was not made out, and consequently, the circumstance did not receive any further attention. It would seem, indeed, that Hadley observed the faint ring as early as the year 1723. In the course of his observations of the planet in that year, he remarked that the dusky line which in 1722 he observed to accompany the inner edge of the ring across the disc, continued close to the same, though the breadth of the ellipse had considerably increased since that time ('Phil. Trans.,' 1723, No. 378). He asserts, moreover, in reference to the hypothesis of the belt being produced by the shadow of the ring upon the planet, that when he considered the situation of the sun, with respect to the ring and the planet, he found that the belt could not arise from such a cause.

From an examination of the recorded measures of the rings of the planet, extending from the time of Huyghens down to the present day, M. Otto Struve was induced to conclude that the rings are gradually approaching the body of the planet. Mr. Main, however, who recently subjected to a thorough discussion his own measures of the Saturnian system, has discovered no trace of the existence of such a movement.

The question with respect to the physical constitution of Saturn's rings, and the mechanical conditions which assure their stability, has naturally given rise to much speculation. Laplace, who investigated the question of stability, concluded that in order to prevent the rings from being precipitated on the body of the planet they must be irregular in their contour. Several succeeding astronomers and mathematicians have considered the same subject. The most complete investigation of it is due to Professor Clerk Maxwell; he concludes that the only system of rings which can exist mechanically is one composed of an indefinite number of unconnected particles, revolving round the planet with different velocities according to their respective distances. These particles may be arranged, in series of narrow rings, or they may move through each other irregularly. In the first case the destruction of the system will be very slow; in the second case it will be more rapid; but there may be a tendency towards an arrangement in narrow rings, which may retard the process.

We shall conclude this article with referring to an admirable delineation of Saturn and his rings by Mr. De la Rue, founded on his own observations with his 13-inch reflector. Several valuable measures of the Saturnian system by Mr. Main, Mr. De la Rue, Mr. Dawes, and other observers, will be found in the recent volumes of the Memoirs and Monthly Notices of the Royal Astronomical Society. In the 28th volume of the Memoirs the reader will find an elaborate investigation of the orbits of the Satellites (except those of Mimas and Hyperion) by Captain Jacob.

SATURNA'LIA, a festival celebrated by the Romans in honour of the god Saturnus. [KRONOS.] According to some traditions, it had been celebrated by the aborigines long before the building of the city, and was instituted by the fabulous king Janus, after the disappearance of Saturnus from the earth. Others said that it was instituted by the Pelasgians, or by the followers of Hercules, who had been left behind in Italy. (Macrob., 'Sat.,' i. 7.) A second set of traditions referred the institution of the Saturnalia to a much later period; one of them ascribed it to King Tullus Hostilius, who, after a successful war against the Albans and Sabines, was said to have founded the temple and established the festival of Saturnus at Rome. (Macrob., 'Sat.,' i. 8.) Another tradition, adopted by Livy (ii. 21) and Dionysius (vi., *ab init.*), which refers it to a still later time, ascribed the institution of the Saturnalia to the consuls A. Sempronius and M. Minucius (497 B.C.). The apparent incongruity of this and some other accounts may easily be removed: those who trace the Saturnalia to a period antecedent to the building of the city, can only mean that the worship of Saturnus was very ancient in Italy, while those who assign a later date to the institution must be understood to refer to the introduction of the worship into the city of Rome; and although festivals in honour of Saturnus may have been celebrated at his altar in the Roman Forum previous to 497 B.C., yet the regular and periodical celebration of the Saturnalia may not have been established before this time, when a temple was dedicated to the god in the clivus leading from the Forum to the Capitol. After this time the Saturnalia were celebrated regularly every year, on the 19th of December, the whole of which month was sacred to Saturnus; but after J. Cæsar had added two days to this month the celebration began on the 17th (Macrob., 'Sat.,' i. 10), and the people, being fond of such merry-makings, continued the festivities until the 19th, and even longer. Augustus at last sanctioned the celebration of the Saturnalia during three days, and Caligula and Claudius increased the number to five days. (Macrob., 'Sat.,' i. 10; Sueton., 'Calig.,' 17; Dion Cass., lix., p. 739.)

The Saturnalia was a harvest festival, and was held, as we have seen, at a time when all agricultural labours were over; and as at such a season every husbandman would naturally give himself and his servants a holiday, and offer his prayers to the god whose especial protection he solicited, so the Saturnalia were national festivals instituted with the same object. It was generally believed that during the golden age of the reign of Saturnus there were no slaves, and the Saturnalia were intended to restore that happy state of things for a short time, by giving to servants and slaves a complete holiday. They were on this occasion allowed to appear in the dress of free citizens (Dion Cass., lx., p. 779), were waited upon at their feasts by their masters, were free from every kind of service, and enjoyed the most perfect freedom of speech. Even criminals were sometimes restored to freedom, and then dedicated their chains to Saturnus. The whole season was one of universal rejoicing for all the people of Rome, and the city resounded with the shouts, "Io, Saturnalia! Io, bona Saturnalia!" Everybody ate and drank plentifully, and invited or visited his friends and relations. It was also customary for persons to make presents to one another on this occasion (Senec., 'Epist.,' 18; Sueton., 'Aug.,' 75), and clients presented their patrons with wax-candles. (Macrob., 'Sat.,' i. 7; Varro, 'De Ling. Lat.,' iv., p. 19, Bipont.) Children generally received little figures, which were called oscilla, or sigilla, from which the last day of the Saturnalia derived the name "sigillaria." During this festival all business, private as well as public, was suspended; no war was commenced, no battle was fought, and no punishment was inflicted on offenders. (Macrob., 'Sat.,' i. 10.) The persons who offered sacrifices to Saturn had their heads uncovered.

The Greek writers, when speaking of the Roman Saturnalia, generally call the feast "Kronia," as they considered the two festivals, as well as the deities in whose honour they were held, Saturnus and Kronos, as identical. (Comp. Buttmann, 'Mythologus,' ii., p. 52, &c.; Hartung, 'Die Religion der Römer,' ii., p. 124, &c.)

SATURNUS. [CHRONOS.]

SATYR (Satyrus, Σάτυρος) is the name by which the ancients designated a class of rustic deities, or Dionysii. Like the Panes and Fauni, they were a kind of intermediate beings between men and animals, and the features which they had in common with the latter were chiefly derived from goats. They were by some said to be the sons of Hermes and Ipthima. They seem originally to have been a sort of rustic or sylvan gods, who were worshipped in some parts of Peloponnesus. In the earlier works of ancient art they are represented with rather long and pointed ears, bald-headed, and with little protuberances like horns behind their ears. Sometimes their figure approached still nearer to the animal form, as they were represented with goats' feet and horns. During the best period of Grecian art the human form is entire, and the animal character is expressed by a little tail at the lower part of the back, and by a considerable degree of sensuality in the features and attitudes. They carry the thyrsus, shepherd's staff, or syrinx, wine-cups, &c., and are clad in the skins of animals, with wreaths of ivy, &c. Satyrs of a more graceful form are seen playing the flute, or, like Ampulus, as cup-bearers to Dionysos. Often, however, especially in later Greek and Græco-Roman art, they are of a lascivious character. Satyrs were the constant companions of Dionysos, and in the Dionysiac processions they always appear dancing, with cymbals or flutes in their hands. In the Greek drama the chorus at the Dionysia originally assumed the character of satellites of Dionysos, —that is, of satyrs,—and it is expressly stated that Arion not only invented the tragic dithyramb, but introduced satyrs, whence, according to some accounts, the name tragedy, or goats' song, arose. But the chorus of the Attic tragedy, in the course of time, gradually lost its satyric character, and a distinct satyric drama was developed, which is described by the ancients as a playful tragedy. The complete separation of this satyric drama from tragedy is ascribed to Pratinas of Phlius.

(Müller, *Archäolog. der Kunst*, § 385; H. C. A. Eichstädt, *De Dramate Græcorum Comico-Satyrico*, Lips., 1793; and, above all, Casaubon, *De Satyrica Græcorum Poesi et Romanorum Satira.*)

SAVANNA. [PLAINS.]

SAVINGS BANKS are institutions of modern invention, established in this country to encourage habits of prudence on the part of the poorer classes, who were previously without any places where they could safely and profitably deposit the small sums which they might be able to set aside from their earnings.

The origin of savings banks has been attributed to the Rev. Joseph Smith of Wendover, who, in the year 1799, circulated proposals, in conjunction with two of his parishioners, in which they offered to receive from any inhabitant of the parish any sum from twopence upwards every Sunday evening during the summer months, to keep an exact account of the money deposited, and to repay at Christmas to each individual the amount of his deposit, with the addition of one-third to the sum as a bounty upon his or her economy. The depositors were at liberty to demand and receive back the amount of their savings, without this bounty, at any time before Christmas that they might stand in need of their money.

The next institution of this kind that was established, of which we have any account, was founded at Tottenham in Middlesex, by Mrs. Priscilla Wakefield. This, which was called the Charitable Bank, bore a nearer resemblance to the savings banks of the present day than the Wendover plan. The Tottenham bank was opened in 1804. At first the accounts were kept by Mrs. Wakefield, who was assisted in other respects by six gentlemen acting as trustees, who undertook each to receive an equal part of the sums deposited, and to allow five per cent. interest on the same to such depositors of 20 shillings and upwards as should leave their money for at least a year in their hands. In proportion as the amount of the deposits increased, additional trustees were chosen, so as to diminish the loss, which might otherwise have been considerable, owing to the high rate of interest that was allowed. In 1808 a society was formed at Bath, managed by eight individuals, four of whom were ladies, who received the savings of domestic servants, and allowed interest upon the same at the rate of four per cent.

The Parish Bank Friendly Society of Ruthwell was formed in 1810 by the Rev Henry Duncan, who published an account of his institution with the hope of promoting similar establishments elsewhere. This was the first savings bank, regularly and minutely organised, which was brought before the public, and it is doubtless owing to the successful example thus set, that previous to 1817 there were seventy savings banks established in England, four in Wales, and four in Ireland.

In the year just mentioned legislative provisions were first made for the management of these institutions. Acts were passed (57 Geo. III. c. 105 and 130) for encouraging the establishments of banks for savings in Ireland and England respectively. Under these Acts, the trustees and managers, who were prohibited from receiving any personal profit or advantage from the institutions with which they should be connected, were required to enrol the rules of their institutions at the sessions. A fund was established in the office for the reduction of the national debt in London, entitled, "The Fund for the Banks for Savings," and to this fund the trustees were bound to transmit the amount of all deposits that might be made with them when the sum amounted to 50l. or more. For the amount so invested the trustees received a debenture, carrying interest at the rate of three-pence per centum per diem, or 4l. 11s. 3d. per centum per annum, payable half-yearly. The rate of interest then usually allowed to depositors was four per cent. In Ireland the depositors were restricted to the investment of 50l. in each year, and in England the same restriction was imposed, with a relaxation in favour of the first year of a person's depositing, when 100l. might be received. No further restriction was at this time thought necessary as to the amount invested, neither was the depositor prevented from investing simultaneously in as many different savings banks as he might think proper. This circumstance was found liable to abuse, and an Act was passed in 1824, which restricted the deposits to 50l. in the first year of the account being opened, and 30l. in each subsequent year, and when the whole should amount to 200l. exclusive of interest, no further interest was to be allowed. Subscribers to one savings bank were likewise not allowed to make deposits in any other.

In 1828 a further Act was passed, entitled "An Act to consolidate and amend the laws relating to Savings' Banks," and it is under the provisions of this Act (9 Geo. IV. c. 92) that all savings banks are at present conducted. It is provided herein, "that the rules of every savings bank shall be signed by two trustees, and submitted to a barrister appointed by the commissioners for the reduction of the national debt, for the purpose of ascertaining whether the same are in conformity to law, and that the said barrister shall give a certificate thereof, which, together with the rules signed by the trustees, shall be laid before the justices for the county, riding, division, or place at the general or quarter sessions; and it shall be lawful for such justices to reject and disapprove of any part or parts thereof, or to allow and confirm the said rules or such parts as shall be conformable to the act." The rules and regulations thus made and confirmed were to be deposited with the clerk of the peace for the county or division, and are then declared to be binding on the officers and the depositors of the institution. The money deposited in savings banks must be invested in the Bank of England, or of Ireland, in the names of the commissioners for the reduction of the national debt. The receipts given to the trustees of savings banks for money thus invested bore interest at the rate of 2½ *per cent. per diem*, or 3l. 16s. 0½d. per cent. per annum, while the interest paid to depositors was not in any case to exceed 2¼ *per cent per diem*, or 3l. 8s. 5¼d. per cent. per annum, the difference being retained by the trustees to defray the expenses of the bank. The trustees were not allowed to receive deposits from any individuals whose previous deposits have amounted to 150l., and when the balance due to any one depositor amounts with interest to 200l., no further interest is to be allowed. Friendly societies and charitable institutions were allowed to invest sums not exceeding 300l.

By another Act (3 William IV. c. 14) the industrious classes were encouraged to purchase annuities, to commence at any deferred period which the purchaser may choose, the purchase-money being paid either in one sum at the time of agreement, or by weekly, monthly, quarterly, or yearly instalments, as the purchaser may determine. The transactions under this act were to be carried on through the medium of savings banks, or by societies established for the purpose, and of which the rector or other minister of the parish, or a resident justice of the peace, shall be one of the trustees.

The 5 & 6 Wm. IV. c. 57, passed in September, 1835, extended the provisions of the 9 Geo. IV. c. 92, and of 3 Wm. IV. c. 14, to savings banks in Scotland, and enabled existing banks to conform to the said acts by preparing and depositing their rules pursuant to these acts.

Military or Regimental Savings Banks were established by warrant dated October 11, 1843.

On the 9th of August, 1844, the royal assent was given to an act (7 & 8 Vict. c. 83) entitled "An Act to amend the Laws relating to Savings Banks, and to the Purchase of Government Annuities through the medium of Savings Banks."

The first clause of this Act reduces, from and after the 20th of November, 1844, the interest of all moneys invested by the trustees of savings banks in the national funds, to the rate of 3l. 5s. per cent.; and s. 2 declares that the maximum of interest to be allowed to depositors shall not exceed the rate of 3l. 0s. 10d. per cent.

From the same date every depositor, on making his first deposit (s. 3), is to sign a declaration as provided by previous Acts, a copy of which is to be annexed to the deposit-book; and once in every year at least this book (s. 5) is to be produced at the institution for the purpose of examination.

Any actuary, cashier, or other person holding a situation at a savings bank (s. 4), receiving deposits and not paying over the same to the managers, is declared guilty of a misdemeanor; but no trustee or manager to be liable (s. 6) for any deficiency unless they have declared in writing their willingness to be so responsible, and this responsibility may be limited, except in cases of money actually and personally received by them.

When deposits are made in trust for another (s. 7), the sum is to be invested in the names of the trustees and the person on whose account the same is so invested; and repayment is not to be made without the receipt of both, or of their trustees, executors, or agents appointed by power of attorney.

Annuities under the 3 & 4 Wm. IV. c. 14 are not to exceed the sum of 30l. in the whole, but separate annuities to that amount may be granted to a husband and wife: but instead of the charges under the former Act, the charges are now (s. 9), for an annuity under 5l., the sum of 5s.; 5l. and under 10l., 10s.; 10l. and under 15l., 15s.; 15l. and under 20l., 20s.; 20l. and under 25l., 25s.; 25l. and not exceeding 30l., 30s.

Where deposits exclusive of interest do not exceed 50l. (s. 10), if a will or letters of administration are not produced within a month, the money may be paid to the widow, or the person entitled to the effects of the deceased; if a depositor be illegitimate and die intestate, the managers (s. 11), with the sanction of the barrister appointed to certify the rules, may pay the same to such persons as would be entitled to the same under the statute of distribution, if all the parties were legitimate; and where a married woman has made deposits it is lawful for the managers (s. 12) to repay such woman, unless the husband give notice to the contrary.

The time for issuing the half-yearly receipts for interest is extended (s. 13) to sixty days from and after the 20th of May and 20th of November; and the time for transmitting the annual statement is extended to nine weeks after the 20th of November in each year.

Any dispute between the depositors and the managers is to be settled (s. 14) by arbitration of the barrister appointed under the previous acts, whose award is to be exempt from stamp-duty; the barrister is empowered for this purpose (s. 15) to inspect the books of the institution, and to examine witnesses on oath or affirmation: false evidence to be punished as perjury.

Bonds given as security under previous acts (9 Geo. IV. c. 92, and 3 & 4 Wm. IV. c. 14) are to be deposited with the commissioners for the reduction of the national debt (s. 16), to be delivered up on the application of not less than two trustees and three managers when required to be cancelled. Every officer trusted with the receipt or custody of money (s. 17) is to give sufficient security; such security, when given by the treasurer, actuary, or any other officer receiving a salary, shall be by bond, which is exempted from stamp-duty.

The direction for depositing the rules of a savings bank with the clerk of the peace (s. 18) is repealed; but two written or printed copies of them are to be transmitted (s. 19) to the barrister for his certificate, who, on approval, is to return one copy to the institution, and transmit the other to the commissioners.

Payments to the relations of intestate depositors (s. 20) are to be made to the next of kin by the law of Scotland, in the case of deposits in that country.

The act is declared (s. 21) to extend to societies for purchasing annuities as well as to savings banks, and (s. 22) to Great Britain and Ireland, Berwick-upon-Tweed, Guernsey, Jersey, and Isle of Man.

The 11 & 12 Vict. c. 133, limits the liabilities of trustees in Ireland, except for money actually received by them and not paid over, to any sum specified by them in writing, not being less than 100l.

By the 16 & 17 Vict. c. 45, the amount of annuities granted is extended to 30l., but still not to be less than 4l., for one or two lives; and they may be granted to a husband and wife, though one may already have secured an annuity to the full amount.

By the 19 & 20 Vict. c. 41, the shipping-offices for saving are constituted branch savings banks, and the Board of Trade is empowered to make regulations for the investment and withdrawal of deposits.

Rules framed in agreement with the statutes have been issued by the commissioners for the reduction of the national debt. These rules provide, among other things, that no person being a trustee, treasurer, or manager of the society, shall derive any emolument, direct or indirect, from its funds; that the treasurer, and the paid officers of the society, shall give security for the faithful execution of their trust; that the age of the party, or nominee, upon whose life the annuity is contracted, must not be under fifteen years; that no one individual can possess, or be entitled to, an annuity, or annuities, amounting altogether to more than 30l., and that no annuity of less than 4l. can be contracted for; that minors may purchase annuities. The annuities are payable half-yearly, on the 5th of January and 5th of July, or on the 5th of April and 10th of October. If any person wishes to have an annuity payable quarterly, that object may be accomplished by purchasing one half payable in January and July, and the other half payable in April and October. Upon the death of the person on whose life the annuity depends, a sum equal to one fourth part of the annuity, beyond all unpaid arrears, will be payable to the person or persons entitled to such annuity, or to their executors or administrators, if claimed within two years. These annuities are not transferable, unless the purchaser becomes bankrupt or insolvent, when the annuity becomes the property of the creditors, and will be repurchased, at a fair valuation, by the commissioners for the reduction of the national debt. If the purchaser of an annuity should be unable to continue the payment of his instalments, he may at any time, on giving three months' notice, receive back the whole of the money he has paid, but without interest; or he may have an immediate or deferred annuity granted, according to the amount of money paid. If the purchaser of a deferred life annuity should die before the time arrives at which the annuity would have commenced, the whole of the money actually contributed, but not with interest, will be returned to his family without any deduction. If a person who has contracted for, or is entitled to, an annuity, becomes insane, or is otherwise rendered incapable of acting, such weekly sum will be paid to his friends for maintenance and medical attendance as the managers shall think reasonable, or any such other payments may be made as the urgency of the case may require, out of the sums standing in the name of the party. Any frauds that may be committed by means of mis-statements and false certificates will render void the annuity, and subject the parties offending to other and severe penalties. The rules of societies formed for carrying into effect the purposes of this Act must be signed by trustees, certified by the barrister appointed for the purpose, and enrolled with the clerk of the peace for the county or division in the manner already described with regard to the rules of savings banks.

Annuity tables, calculated under the direction of government, for every admissible period of age, and for every probable deferred term, may be had at the office of the commissioners for reducing the national debt, in the Old Jewry, London.

These measures appear to be well calculated for enabling the industrious classes to secure a small provision in the time of their youth and strength, for the days of their age and decline, and for inciting them, while yet unencumbered, to apply the surplus of their earnings to meet the wants of those who may become connected with or dependent on them in after-life.

The growth of these societies has been continuous from their establishment. We give below the number and amount in 1833, and add those of 1859; but it should be remembered that when the amount reaches 200*l.* it is usually transferred to the public funds, as interest is no longer paid. On the 20th of November, 1833, there were 385 savings banks in England holding balances belonging to 414,014 depositors, which amounted to 13,973,243*l.*, being on an average 34*l.* for each depositor. There were at the same time in Wales 23 savings banks, having balances amounting to 361,150*l.* belonging to 11,269 depositors, being an average of 32*l.* for each depositor; while in Ireland there were 76 savings banks, with funds amounting to 1,380,718*l.*, deposited by 49,872 persons, the average amount of whose deposits was 28*l.* The total for England, Wales, and Ireland was consequently 484 savings banks, with funds amounting to 15,715,111*l.*; the number of accounts open was 475,155, and the average amount of deposits was consequently 33*l.*

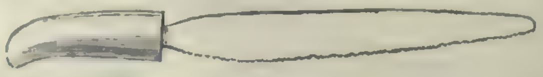
On November 20th, 1859, the total amount of deposits, including interest, in the United Kingdom, was 38,995,876*l.* The number of individual depositors was 1,479,723, of whom 213,473 were depositors of sums not exceeding 1*l.*, 294,739 not exceeding 5*l.*, 194,133 not exceeding 10*l.*, 140,092 not exceeding 15*l.*, 86,250 not exceeding 20*l.*, 148,575 not exceeding 30*l.*, 121,501 not exceeding 40*l.*, 58,032 not exceeding 50*l.*, 98,380 not exceeding 75*l.*, 45,580 not exceeding 100*l.*, 30,700 not exceeding 125*l.*, 18,134 not exceeding 150*l.*, 28,482 not exceeding 200*l.*, and 1652 above 200*l.* There were also 16,315 Charitable Institutions, with deposits amounting to 802,341*l.*, and 10,738 Friendly Societies, with deposits amounting to 1,731,095*l.* There were 580 Friendly Societies with direct accounts with the commissioners for the reduction of the national debt, their deposits amounting to 2,001,754*l.* The number of annuities granted through Savings Banks or Parochial Societies, from the commencement in 1854 to January 5, 1860, was 9707 immediate annuities, amounting to 196,112*l.*, for which 2,064,812*l.* had been paid, and of which 3046*l.* of the yearly amount of 59,432*l.* had fallen in; 160 deferred annuities on payment of one sum, to the amount of 2704*l.*, for which 30,979*l.* had been paid, and of which 26*l.* of the yearly amount of 478*l.* had fallen in; and 1875 deferred annuities for annual payments, to the amount of 37,486*l.*, for which 187,622*l.* had been paid; of these 1110 had fallen in, to the yearly amount of 21,390*l.*, and 44,037*l.* had been returned in consequence of death or default.

In November, 1858, the total amount of securities given by managers and trustees of savings banks had been only 67,070*l.*, and these almost entirely in Ireland.

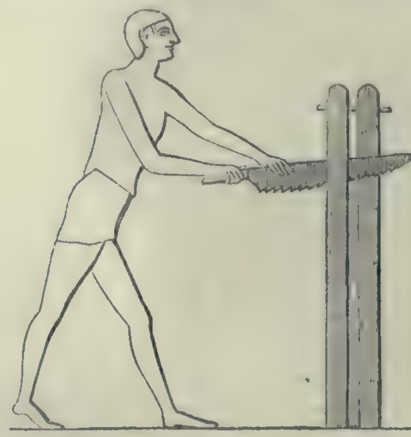
Much useful information as to the formation, management, and the means of ensuring the security of savings banks, will be found in 'A Practical Treatise on Savings Banks,' by Arthur Scratchley, M.D., 1860.

(*History of Savings Banks*, by J. Tidd Pratt; *The Law relating to the Purchase of Government Annuities through Savings Banks and Parochial Societies*, by the same author.)

SAW AND SAW-MILL. The division of wood by riving or splitting was probably the most ancient method of reducing it to pieces of convenient size and shape. If the grain of timber were straight, this plan would have the advantage of economy; but as it is not so in general, considerable waste is occasioned by riving when the pieces are required to be straight, much wood having to be removed with an adze in order to make it so. Hence the invention of saws.



Saws were used by the ancient Egyptians. The annexed cut represents a saw that was discovered, with several other carpenters' tools, in a private tomb at Thebes, and which is now preserved in the British Museum. The following cut, from Rosellini's work on Egyptian antiquities, represents a man using a similar saw; the piece of wood which he is cutting being held between two upright posts. In other representations the timber is bound with ropes to a single post; and in one, also copied by Rosellini, the workman is engaged in tightening the rope, having left the saw sticking in the cut. There is a curious picture among the remains discovered in Herculaneum, representing a carpenter's workshop, with two genii cutting a piece of wood with a frame-saw. On an altar preserved in the Capitoline Museum at Rome there is a representation of a bow-saw, exactly resembling in the frame and the twisted cord those used by modern carpenters.



Saws are of various forms and sizes. Those used by carpenters and other artificers in wood are the most numerous. Among these are the following:—The *cross-cut saw*, for dividing logs transversely, two persons being employed to pull the saw backwards and forwards, and the teeth being so formed as to cut equally in both directions. The *pit-saw*, with large teeth, and a transverse handle at each end. It is used for sawing logs into planks, the piece to be cut being laid over a saw-pit six or seven feet deep. One man stands on the log, and the other in the pit, and they pull the saw alternately up and down, the saw cutting in its descent only. The *frame-saw* is from five to seven feet long, stretched tightly in a frame of timber, the plane of the saw being at right angles with that of the frame. It is used in a similar manner to the pit-saw, but causes less waste, because the blade, being stretched, may be made much thinner. The *ripping-saw*, *half-ripper*, *hand-saw*, and *panel-saw* are saws for the use of one person, the blades tapering in width from the handle. They are of different lengths, the largest being about twenty-eight inches; and the teeth vary from one-third to one-eighth of an inch. *Tenon-saws*, *sash-saws*, *dovetail-saws*, &c., are very thin, of equal width throughout their whole length, and stiffened with stout pieces of iron or brass fixed on their back edges. These are used for many purposes for which a neat clean cut is required, but where it is not necessary for the whole width of the saw-blade to pass through the wood. *Compass* and *key-hole saws* taper from about an inch to an eighth of an inch in width, and are used for making curved cuts. Small *frame-saws* and *bow-saws*, in which very thin narrow blades are tightly stretched, are occasionally used for cutting both wood and metal. Saws are made for cutting bone, iron, brass, and many other hard substances; and there are several varieties used by the carpenter besides what have been enumerated; but it is unnecessary here to detail them.

The very commonest kind of saws are made of iron-plates, hammer-hardened, and planished upon an anvil, to give them some degree of stiffness and elasticity. The more useful saws are made either of shear or cast steel. The steel is cast in the form of a small slab, about an inch and a half thick. This slab is extended, by rolling, to the required degree of tenuity, and then cut, by shears, into pieces of suitable form and size. The edges are next perfected by filing, and holding the flat side of the plates against large grindstones, which process prepares them for the cutting of the teeth. This operation is usually performed by a die-cutter in a fly-press, the motion of the saw-plate being duly regulated, so that the teeth shall be uniform; the larger teeth being cut one at a time; and the smaller two, three, or more at a time, according to circumstances. The wire edges left on the teeth by the cutting-out press are removed by filing; after which the plates undergo the processes of hardening and tempering. They are heated to a cherry-red and dipped into a fatty composition. When sufficiently cooled therein to be handled, they are taken out, and are found to be extremely hard and brittle. They are passed backwards and forwards over a clear charcoal fire, so as to cause the unctuous matter to inflame, or *blaze off*, as it is termed, which reduces the saws to the required temper; and, whilst the saw-plates remain hot, any warping they may have acquired in the process is removed by smart blows from a hammer. The next operation is planishing by hammers, to make them more even and equally elastic: after which the saws are ground on large grindstones. As the grinding impairs the elasticity, they are submitted to a second hammering, and to heating over a coke fire until they attain a faint straw-colour. The marks of the hammer are removed by again passing the saws lightly over a grindstone; after which the final polish is given by a fine hard stone, a glazing-wheel covered with buff-leather and emery, or a wooden wheel, called the *hard-head*. Any defects acquired during these processes are removed by a few blows with a small polished hammer upon a post of hard wood. The saws are "cleaned off" by women, by rubbing fine emery over them lengthwise with a piece of cork-wood. The *setter* lays each alternate tooth over the edge of a small anvil, and strikes them so as to bend each uniformly into a slight deviation from the plane of the saw; and then, turning the saw-plate, sets the remaining teeth in like manner, but in the opposite direction. The degree of deviation from the plane of the saw depends upon the kind of wood to be cut; the softest wood requiring the widest or *rankest* set. Sometimes an instrument with a notched edge, called a *saw-wrest*, is used for setting the teeth. After being set, the saw is placed, between two plates of lead, in a vice, and the teeth are sharpened with a triangular file. The handles are then fixed on by nuts and screws, and the saws cleaned off, oiled, and packed in brown paper for sale.

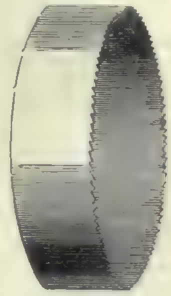
The teeth of carpenters' saws are so formed as to contain an angle of 60°, and they are made to incline more or less forward according to the intended use of the saw. Ripping saws have the front of the teeth perpendicular to a line ranging with their points. For very delicate operations saws are frequently made of watch-spring.

Saws for cutting stone are without teeth, although they are sometimes slightly notched upon the cutting edge. The saw-plate is tightly stretched on a kind of rectangular frame, of which it forms the lower side; and the frame, being suspended by ropes, is moved backwards and forwards by one or two men. Coarse sharp sand is used for cutting soft stones, and fine sand for those of harder quality. Sawing stone is a very slow and laborious operation. As in saw-mills for wood, any number of saws may be worked together, so adjusted as to cut a block of stone into slabs of any required thickness.

Saw Mill.—The machinery used for the purpose of converting wood from the log into squared lumber, or for subsequently cutting it up into plank, or veneer stuff, is known in the arts under the generic name of *saw mill*. It consists of a prime mover, setting in operation either a circular plate with serrated edges, vertical saw blades fixed rigidly in a frame, or a series of knife blades forming the segments of a large circular plate bearing a sharp cutting edge; and at the same time motion is communicated by the prime mover to a ratchet-wheel, which causes the frame to advance horizontally so as to keep the log of wood to be operated upon in actual contact with the edge of the cutting-tool. Rough logs and scantling stuff are cut by the circular saw; and deals, battens, and planks are dressed for the market by the same description of machinery. Thin boards (between 1¼ inch and ½ of an inch in thickness) are cut by the frame saw; and veneers, or thin slices of the harder and more precious woods, are cut by the plate saws with knife edges. As many as 100 veneers are at times cut out of planks only 1 inch in thickness.

The prime motors of saw mills may be either water-wheels, windmills, or steam-engines, and even in some cases horse-power is used. In mountainous districts, such as are usually covered with forests, water-wheels can generally be economically established, and they are rarely used for any other purpose than for squaring logs, or dressing plank stuff. Windmills are largely used in such countries as the Fens of East Anglia, and Holland, for both circular saws and frame saws; whilst the application of steam power to this purpose is the system almost universally adopted, in countries where fuel is cheap, for the ordinary kind of saw mills, and it is the only motive power ever employed for veneer cutting. Of late years, circular saws have been used for the purpose of cutting the ends of iron rails, and they also are invariably worked by steam power. The sizes of circular saws vary from 4½ to 60 inches in diameter; vertical saws are made of cast steel of Nos. 13, 14, and 15 gauge, and from 4 to 8 inches wide by from 3½ to 7 feet in length; veneering saws vary from 4 to 10 or 12 feet in diameter.

All the varieties of apparatus that have been described are for the purpose of making *straight* cuts; but it is sometimes desirable to produce *curved* forms by sawing, for which purpose there are several ingenious contrivances. Mr. Trotter has invented a concave circular saw, resembling a watch-glass in form, which is mounted in a bench like the common bench-saw, and to which the wood is directed by curved guides. Many useful forms are cut by a saw consisting of a cylinder of steel, toothed on the edge. Such saws are used for cutting circular pieces of wood to form the sheaves of blocks; and, when of larger dimensions, for cutting chair-backs, felloes of wheels, curved brush-handles, &c. For these purposes they are sometimes used as much as five feet in diameter. In another machine, an arrangement resembling the common reciprocating saw-mill is applied to curvilinear sawing, by causing the carriage on which the timber is supported to deviate from the straight course, and follow the curvatures of a model of the required form; while the saws, being attached to the frame by pivots, are capable of adapting their position to the curve.



Among the recent inventions in saw-machinery is a beautiful apparatus called the *band-saw*. It consists of a very long, narrow, and thin saw, made of highly tempered steel, and so flexible as to be wound round two rollers placed at such a distance apart as to keep the saw always on the stretch. When the rollers rotate, the saw is put in motion, and it thus becomes an endless saw, applicable to many purposes in the finer kinds of carpentry and joinery. Messrs. Powis and James's band-saw, patented in 1858, is an elegant example of this kind.

SAXON ARCHITECTURE. Until recently, all those old English churches of which the doors and windows had semicircular arches were usually termed Saxon. More careful study of our architectural antiquities showed that these were for the most part of Norman date; and it was then by many somewhat hastily assumed to be at least doubtful whether there were any buildings remaining of Saxon construction. That there are churches which were in part erected prior to the Norman Conquest there is now, however, no longer any dispute. Their number is indeed small, as might be expected; for the condition of the people, the disturbed state of the country, and the ravages of foreign invaders, would either prevent many churches, except of a comparatively rude character, being erected, or account for their destruction; and it will be readily perceived how churches which remained at the Conquest, would, one after another, with the progress of refinement be removed to make way for others of a costlier character, or more fashionable style of architecture; and that consequently, after the lapse of 800 years, but few fragments of such buildings should be extant.

Yet some vestiges, as we said, are left. Mr. Bloxam, who has paid particular attention to the subject, gives in the last edition of his 'Gothic Architecture' (1859, p. 90) a list of more than 90 churches (46 of which he has himself examined), which contain portions of presumed Saxon architecture. Mr. Rickman believed he had verified the existence of such remains in 120 churches.

Saxon architecture would be best described as the earliest form of Anglo-Romanesque. [ROMANESQUE ARCHITECTURE.] The earliest Anglo-Saxon architects made use of the materials of the Roman buildings, wherever they could obtain them, and imitated the Roman workmanship. In the brick walls and semicircular arches of the oldest Anglo-Saxon buildings, there are evident attempts to copy what is called the herring-bone work of the debased Roman architecture which prevailed in England. But the buildings were constructed by, or under the direction of, ecclesiastics who had acquired on the continent the current taste in ecclesiastical architecture; and who carried out their views as well as the skill of the workmen and the materials at their command permitted. For the more important buildings—and there are accounts in the chronicles of the erection of cathedrals and monastic edifices of considerable importance—foreign workmen were brought over. Accordingly, we find throughout the period a reference more or less direct to continental models, and, as might be expected from the connection of the court and the clergy, towards the latter part, a growing approximation to the Norman taste.

The style extends over a period of nearly four hundred years—from the latter part of the 7th to the middle of the 11th century. It is usually divided into two periods, the first extending to nearly the end of the 10th century, the second continuing to the Conquest. But the second period is that when the Norman influence prevailed, and when the style differed in little from the Norman but in its being less refined and artistic. [NORMAN ARCHITECTURE.] Here, therefore, it will be enough to indicate a few of the distinctive characteristics of the older variety.

No complete Anglo-Saxon church remains; but from those which are most perfect, as Brixworth in Northamptonshire, and from the references in Saxon records and the drawings in manuscripts, we see that the churches were rude, plain, and massive in appearance, and that whether cruciform, or with nave, side-aisles, and a tower at the west end, the chancel was usually apsidal. [APSIS.] Crypts appear to have been not uncommon in the larger churches, and a tolerably perfect one is still extant beneath the chancel of Repton church, Derbyshire. Towers were commonly very massive, divided into two or three stories by the rib-work described below; the surface being also divided by strips of similar rib-work, and having at the angles quoins of long-and-short work. The walls, where surmounted with a spire, or rather spire-roof, seem to have mostly had a gable-like termination; of this gable termination a good example remains in the tower of Sompting church, Sussex, though the roof-spire has been lowered. Of a more elaborate tower, Earl's Barton, Northamptonshire, is one of the most perfect existing examples. From their solidity of construction, the towers have proved the most lasting parts of Saxon churches.

The walls were usually built of coarse rag-stone, rubble, or flint, having as bonding at the angles oblong quoins set alternately upright and horizontal, so as to form what is called long-and-short work. Narrow ribs or strips composed of alternately long and short pieces of stone, projecting a few inches from the surface, are carried vertically up the face of the wall, and have been variously supposed to be rude imitations of pilasters or of timber-work. The piers were low and thick. The arches are either triangular, as at Brigstock, or, as is more common, semicircular. Windows are small; mostly, in fact, mere narrow openings. Sometimes, and the belfry-windows commonly, they consist of two semicircular-headed windows, divided by a thick and variously shaped baluster-shaft. Occasionally these double windows are enclosed within an arch or hood, formed of the pilaster rib-work above described: engravings of all these varieties will be found in Bloxam (ch. iii.), and other works on English Gothic architecture. The chancel arches are commonly small and quite plain, or have at most a moulded hood rudely worked on the face. Doorways have either semicircular or triangular arches: the former spring from plain projecting imposts, and are encircled with a hood of long-and-short rib-work which is usually carried down to the ground.

Mouldings are few and plain. In the later examples semi-cylindrical roll mouldings are not infrequent. In the older churches sculpture is seldom found; but later, rudely carved animals and flowers, knot-work, Greek crosses in relief, and other ornaments, are let into the walls. The imposts from which the arches spring are commonly mere rude massive blocks left square and plain, but they are sometimes moulded, and are occasionally rudely sculptured, as at Sompting, Sussex. Plain square string-courses are often met with; and inscriptions seem to have been not uncommon. The distinctive features of the style are, however, the long-and-short work of the quoins, the pilaster rib-work, the triangular arches, and the baluster-shafts of the belfry windows: the other particulars are not infrequent in early Norman work.

SAXON BLUE. [COLOURING MATTERS.]

SAXON LANGUAGE AND LITERATURE. The terms Saxon and Anglo-Saxon are popularly used to designate that dialect of our language which prevailed to the close of the 12th century. The use of these terms is, however, comparatively modern, and the men who spoke this dialect always called it the English. Several of our manuscript chronicles begin thus:—"Britain island is eight hundred miles long, and two hundred miles broad. And there are in the island five languages, *Ænglish*, and Brit-Welsh, and Scottish, and Pightish, and Book-Latin," &c. Still we may use these terms with some convenience, and (thus cautioned) without any danger of being misled. We proceed to point out the peculiarities which distinguish the Anglo-Saxon from the succeeding dialects of our language.

The Anglo-Saxon, like the Latin and the Greek, often distinguished the cases of its noun, and the conjugations, numbers, and persons of its verb, by a change in the vowel of the final syllable; in the dialect which succeeded, and which has been called the Old English, all these vowels were confounded, and in our modern dialect they have, for the most part, been lost. Thus the Anglo-Saxon *ath* has *athas* in the nominative and accusative plural, and *athes* in the genitive singular; the Old English *ath* has *athes* not only for its genitive singular, but also for its nominative and accusative plural; and in our modern English these three cases are all represented by the monosyllable *oaths*. Again, in the Anglo-Saxon, *athe* was the dative singular, and *atha* the genitive plural; in the Old English, *athe* represented both dative singular and genitive plural; and our present dialect, having lost the final vowel, had no means left of distinguishing these cases from the nominative *oath*. The third person singular of *lufian* was *lufath*, and the first, second, and third persons plural *lufiath*; in the Old English, *loveth* represented both numbers, and *lov'th* is the third person singular in the *spoken* language of the present day.

We say "spoken language," because our *grammarians* make *eth* the ending of the third person singular. But in Somersetshire, west of the Parret, where the southern dialect still lingers, they uniformly say *he lov'th, he read'th, he see'th, it rain'th*, &c. (Jennings, 'Obs. on the West. Dial.') We have very satisfactory evidence, that in the 16th and 17th centuries this dialect was general throughout the south of England, and we find numerous traces of its peculiarities in the literature of that period. Dolman wrote the following passage, in the 16th century:—

> "So, mid the vale, the greyhound seeing stert
> His fearful foe *pursu'th*, before she *flert'th*,
> And where she *turn'th*, he *turn'th* her there to beare,
> The one prey *prick'th*, the other safeties feare."
>
> *Mirr. for Mag.* Hastings.

Spenser has *melt'th* and *hat'th*, and Sackville *leap'th*. It is probable, that the inflexion used by the translators of the Bible, and which is found in other contemporary works, was merely an old form, taken from the language of books, and adopted chiefly with the view of raising the style. The same observation will apply to *est*, the inflexion of the second person singular, and to some other endings, which are still preserved entire in our grammars, though they have lost their vowel in the spoken language, for the last two centuries.

It is obvious, that either of the changes above noticed must have brought with it a new language. When, in the 12th century, the vowels of the final syllables were confounded, there was at the same time a confusion of case and number, of tense and person,—in short, of those grammatical forms to which language owes its precision and its clearness. A writer had to seek for new forms of expression before he could convey his meaning clearly. As he had lost the means of distinguishing several cases of his noun, he called in the prepositions to his aid, and to show more clearly the "regimen" of his sentence, was obliged to confine within very narrow limits the position of his verb,—thus abandoning all that freedom of transposition, which is almost as remarkable in the Anglo-Saxon as in the Greek and Latin. The confusion introduced into his conjugations and tenses, he sought to remedy by various devices, which have hitherto been very little investigated, and at last he had recourse to that general use of the auxiliary verbs, which is at present so marked a feature in the language. The new dialect which resulted from these changes kept its ground for nearly two centuries. It exhibits the most striking analogies with the contemporary dialects of Germany and the Netherlands, and the further changes which converted it into our modern English were rapidly working a like revolution in these sister-tongues, when the invention of printing doubled the influence of their written language, and thus preserved them from further corruption.

In tracing the causes which melted down the Anglo-Saxon into the Old-English, we have not once alluded to the influences supposed to have been exercised by the French language. The popular notions on this subject are, we believe, most erroneous. Had Harold been the conqueror at Hastings, the Anglo-Saxon must have perished, just as the Old-German perished in Germany, and the Old-Norse in Denmark. The victory of William merely hastened by a few years an event that was inevitable. The use of Norman-Romance as the court language of England rendered unfashionable a literature already too weak to stem those changes to which the language of a busy adventurous people is peculiarly liable; and thus far the Norman conquest may be considered as having assisted in the destruction of the Anglo-Saxon. But the vulgar notion, that it produced a mixed language, a jargon composed half of English and half of French, is wholly at variance with the manuscript literature of that period. The Ormulum, in which all the peculiar features of the Old-English are developed, and not a trace of the Anglo-Saxon can be found, is almost as free from *Gallicisms* as any of our manuscripts written before the Norman-French existed. The same may be said of most of the Old-English manuscripts of the 13th century, and it is not till we approach the latter half of the 14th century that we find those "cart-loads" of French words poured into the language, of which Skinner complains so loudly. We must reluctantly agree with this writer, in charging upon Chaucer much of the mischief resulting from these importations—not that he first introduced, but that his authority chiefly sanctioned them. The learned but pedantic writers of the Elizabethan era, and, at a later period, Johnson, followed his example.

Having noticed the changes which converted the Anglo-Saxon into the Old-English, we will now call the reader's attention to a subject of rather difficult inquiry—its local dialects. It is abundantly clear that the Romans looked upon all the Gothic races as forming but one people, and as speaking the same language; but a comparison of the Anglo-Saxon with the Moeso-Gothic, as well as the analogy of other languages, may convince us that even thus early there were dialects, and these dialects have now been acted upon by various influences for nearly 2000 years, till they have at last arranged themselves into four great families—the Northern, the English, the Low-Dutch, and the High-Dutch. Now we have ample proof that the *Seaxe* came from the south-western corner of the Cimbric Chersonesus, and that they were only separated by the Elbe from the Netherlands, or that alluvial country, where the Low-Dutch was spoken. We know also that the Engle came from the eastern coast, and that they were separated from the Danish islands merely by a narrow arm of the sea. We might then expect that in the counties colonised by the Engle we should find many peculiarities of the Northern languages, and in the counties colonised by the Sexe much that reminded us of the Netherlandish or Low-Dutch. We believe the Northern and Southern dialects of our island have been at all times distinguished by such peculiarities, but so few early records have come down to us written in the pure dialect of our northern counties, that it is only by comparing them in the second or Old-English stage of their progress that we can form any just notion of their distinguishing features. Perhaps these are best seen in the conjugation of the verb. The following table may show us how closely the inflexions which distinguish our northern dialect agree with those of a Swedish conjugation :—

	South Dialect.		*North Dialect.*		*Swedish.*	
Pres.,	Ich	hop-e	I	hop-es	jag	hopp-as
,,	thu	hop-est	thu	hop-es	du	hopp-as
,,	he	hop-eth	he	hop-es	han	hopp-as
,,	we	hop-eth	we	hop-es	vi	hopp-as
,,	ye	hop-eth	ye	hop-es	I	hopp-ens
,,	they	hop-eth	they	hop-es	de	hopp-as
Perf.,	thu	hoped-est	thu	hoped-es	du	hoppad-es
Imper.,		hop-eth ye		hop-es ye		
Infin.,	to	hop-en	to	hop-e	att	hopp-as

The inflexions in *s* are generally used in the Northern languages with a passive meaning; and there are some traces of their having been used in our Northern dialect for the same purpose.

Another peculiarity of our Northern dialect is the frequent use of the substantival ending *er* (in which it again resembles the languages of Northern Europe), as *wulfer*, a wolf; *hunker*, a haunch; *teamer*, a team; *heather*, heath; *fletcher*, a fletch, &c.

In this dialect we have also a less frequent use of the articles, conjunctions, and personal pronouns. This is one of its most striking features. Every person who has been in the North of England must have heard such phrases as "come out o' house," "gang into field," "put'n in poke," &c.

All these peculiarities of our Northern dialect may be traced to the Anglo-Saxon period; and there is little doubt that the most striking feature of the Southern dialect, namely, its preference of the vocal to the whisper letters, as *z* for *s*, and *v* for *f*, is equally ancient. It always prevailed in the Netherlandish dialects, and may be traced in the orthography of our Southern manuscripts to the beginning of the 13th century; but, as the Anglo-Saxons had neither a *v* nor a *z*, it is only by analogy we infer the existence of the corresponding sounds in their language. The argument however from analogy is so strong, that we may safely conclude either that the Anglo-Saxon *f*, *s*, were pronounced in our southern counties as *v*, *z*, or that, like the modern *s*, they represented both a whisper and a vocal sound; in other words, were pronounced sometimes as *f*, *s*, and sometimes as *v*, *z*.

It may possibly be asked, were not the forms here attributed to our Northern dialect introduced by the Danes? Are they not, in fact, the peculiar features of the "Dano-Saxon?" We will not affect to treat these questions as altogether without difficulty; but there are some considerations which may be laid concisely before the reader, and which, if they appear to him as forcible as they appear to us, may lead him to answer these questions in the negative.

In the first place, it must be remembered, that if no Dane had ever set foot on the island, the very results which *have* taken place might have been expected. It is also an argument of weight, that we find all the great features of our Northern dialect in places where there never was a Danish settlement, and vainly search for them, or at best only faintly trace them, in counties where we have historical evidence that the Northmen were numerous. But the strongest argument may be drawn from the pages of our Northern manuscripts. We have two of very ancient date—the Gloss of the Durham Bible, written by a priest named Aldred, and the Durham Ritual, published by the Surtees Society. The first of these was written, according to Wanley, in the age of Alfred, and the second has been assigned by its editor to the early part of the 9th century. If we can rely on the judgment of either of these antiquaries, the question seems to be answered; for there was no Danish settlement in the north of England till a later period; and we have the Northern conjugation and other peculiarities of the Northern dialect in every page of the Gloss, and in many parts of the Ritual. The name too of Aldred is thoroughly English; and we can hardly suppose that the monks of Durham would have permitted a rude and unlettered foreigner to interpolate their most precious manuscript—a volume which we know they regarded with even superstitious veneration. The language used by Aldred was probably a mixture of the written language of the day and the spoken dialect of his shire, such as might be used by a provincial writer of the present day, and such as was avowedly used by Gawin Douglas in the 15th century, and at a later period by Burns.

This mixture of the written and the spoken language in our manuscripts, and the total extinction in many counties of our local dialects, render it extremely difficult to point out the limits within which our two great dialects were spoken. Layamon, whose language seems clearly to belong to the Southern dialect, is described in all the histories of our poetry as a native of South Gloucestershire; but the localities mentioned in his poem belong to the north of Worcestershire; and he was, beyond doubt, an inhabitant of Areley-Regis near Stourport in that county. If he used the dialect of the neighbourhood (and this must be assumed till the contrary be shown), the Southern dialect must have prevailed over the whole of Worcestershire, and the men of that shire must have been Sexe in origin, and not, as hitherto supposed, a colony of Engle. Perhaps a line drawn from the north of Essex to the north of Worcestershire would pretty accurately define the portions of the island respectively colonised by the Engle and the Sexe.

The origin of the Midland dialect may admit of the following explanation. Neither natural obstacles nor political divisions ever separated the Northern and the Southern dialects. During the heptarchy, Gloucestershire and Oxfordshire belonged to Mercia, and not to the kindred race of the West-Sexe; and when the Danes held possession of the north of England, the shires of Warwick and Northampton, and generally that of Leicester also, were united in the closest ties with the Southern countries. This fellowship seems to have led, at a very early period, to the use of an intermediate dialect, which would naturally be encouraged by the vast numbers that flocked from all parts of the country to the universities. The 'Reve's Tale' affords us a specimen of the ridicule which attached to the forms of Northern speech, and we know that the speech of the Southern was treated with just as little ceremony in the north of England. (See 'Towneley Mysteries.') Hence we may understand the progress made by the intermediate dialect, and are prepared for the conclusion, to which we are led by an examination of our Old-English manuscripts, no less than by the express declaration of a contemporary philologist. Higden, who lived in the 14th century, ranges our provincial dialects under three heads, the Northern, the Midland, and the Southern; and this division seems to have been generally recognised by our antiquaries, for in our catalogues we find some manuscripts noticed as belonging to our Southern dialect, others as belonging to the Northern, while many of them, exhibiting the marked peculiarities of neither dialect, are passed over without remark.

The change which gradually produced the Midland dialect most probably first showed itself in the counties of Northampton, Warwick, and Leicester. It seems to have been brought about not so much by adopting the peculiarities of Southern speech, as by giving greater prominence to such parts of the native dialect as were common to the South. The Southern conjugations must at all times have been familiar, at least in dignified composition; but other conjugations were *popularly* used, and in the gradual disuse of these and other forms peculiar to the North the change consisted. We have many manuscripts written in the Midland counties, in which all trace of the Northern dialect seems to have been studiously avoided; yet in very many of them may be found some verbal inflexion in *es*, or some other popular form, quite sufficient to betray the writer.

The Northern dialect was still broadly spoken, within the last three centuries, in the counties of Lincoln, Rutland, Derby, and Stafford; but it has been gradually giving way before a language so much more widely understood, till it is now to be found only in scattered localities amid the mountains of the north of England, or in the lowlands of Scotland. The Southern dialect began to yield at a later period. It was certainly spoken at the beginning of the 17th century in all the counties round London. For specimens of the Middlesex dialect see Ben Jonson's 'Tale of a Tub;' 'Lear,' iv. 6, furnishes us with an example of the Kentish dialect; and nearly one half of 'Gammer Gurton's Needle' is written in the same dialect of Essex. Milton, when he issued forth

> "To breathe
> Among the pleasant villages and farms,"

must have heard a dialect around him in all essential particulars the same as the Somersetshire.

We will now take a rapid survey of the literature which belongs to the language whose history and peculiarities we have been endeavouring to trace. As in the case with the literature of most nations, we find that all its earlier specimens are metrical. We will therefore first call the reader's attention to our Anglo-Saxon poems; and to define more clearly the range of our present inquiry, we will briefly notice the properties which, at that early period, distinguished verse from prose.

An Anglo-Saxon verse is made up of two sections, which together may contain four, five, six, or even more accented syllables. These sections are bound together by the law of alliteration, or, in other words, each verse must have at least two accented syllables (one in each section) beginning with the same consonant or with vowels. Sometimes, and particularly in the longer verses, there are two such alliterative syllables in the first section, as in the verse

met | od for | thy *man* | e——*man* | cynne fram |

It is very incorrect to call this alliteration the "essence" or the "groundwork" of Anglo-Saxon verse. It is certainly an important part, but still a mere adjunct. The purposes it served were similar to those which are provided for by the final rhyme of our modern versification. The essence of Anglo-Saxon verse consisted in its system of rhythm. As the accents generally varied from four to six, it may be thought that the rhythm was too vague and loose, but in practice it is generally found sufficiently definite; and there are some of its rules which certainly give it a more scientific character than belongs to the system that has superseded it. For example, no sentence, nor any important member of a sentence, could end otherwise than at the close of a section. In our modern poets we often find a sentence ending in the midst of a section, or even immediately before the last syllable of the verse:—

> "His peers
> Have found | him guil | ty—of high-trea | son. Much—
> He spoke and learnedly for life," &c.;

but such a verse would not have been tolerated in an Anglo-Saxon poem. We may indeed find scores of such verses in the printed editions of these poems; but not one single example, and we speak advisedly, in any Anglo-Saxon manuscript.

The 'Gleeman's Song' is the oldest specimen extant of Anglo-Saxon literature. It is found in what is called the Exeter manuscript, one of the books left by Bishop Leofric to his cathedral, about the middle of the 11th century. Of the Gleeman himself we know nothing, save what can be learned from the poem; but from certain passages in it we may gather that he was born among the Mirgings, a tribe which dwelt on the marches that separated the Engle from the Swefe in the 4th century. In early youth he attended a Mirging princess named Ealhild to the court of Eormanric, the celebrated king of the East-Goten, and who figures so often in Roman history under the name of Ermenricus. ('Amm. Marc.' xxxi. 3, &c.) His professional skill appears to have gained him the favour of this monarch, and of the great lords who frequented the court, and whom he visited in their respective governments. He afterwards accompanied a Mirging prince into Italy, probably during the inroad of Alaric, A.D. 401; and as Gothic leaders were now rapidly gaining a footing in the empire, he seems to have seized the opportunity of wandering through its provinces. On his return, he must have been an eye-witness of the wars waged between Ætla (Attila) and the East-Goten; and as Ætla's accession dates only in 433, and Eormanric died in 375, he must have been more than seventy when he wrote the poem.

The 'Gleeman's Song,' like many other Anglo-Saxon poems, has a short preface in verse, which appears to be of almost equal antiquity with the poem.

Then follows a list of celebrated kings, from which the Gleeman selects for special notice Alexandreas, who appears to be Alexander of Macedon, and Wala, who is, no doubt, the Wallia that founded the kingdom of the Visigoths at Toulouse, A.D. 417. With the exception of Alexander, all of them appear to have been the Gleeman's contemporaries. After this enumeration he proceeds—

> "So I fared through many stranger lands,
> Through the wide earth; of good and evil
> There I tasted; from family parted,
> From kinsmen far, widely I did my suit—
> Therefore may I sing, and story tell,
> Relate fore the crowd, in mead-hall,
> How me the high-born with largess blest.
>
> I was with the Huns," &c.

We have then the names of nations and of countries visited by him, which appear to be strung together in the order best suited to the alliteration. There are also certain notices of the great people by whose bounty he had benefited, and the reader will not be surprised at the Gleeman seeing only a liberal patron in the same monarch (Eormanric) whom the author of the preface denounces as "a wrathful treachour." The whole concludes with a short eulogy on the dignity and privileges of his craft.

The great value of this poem lies chiefly in that string of names, which we have omitted as being so little interesting to the general reader. We do not stop to examine the question, whether any or how many of these notices have been interpolated during the five centuries which elapsed between the composition of the poem and the writing of the manuscript. Our knowledge of early Saxon history is so scanty that all such speculations must be hazardous. But we may observe, that the Scriptures had been translated into a Gothic dialect long before the Gleeman began his wanderings, and we know from Roman history that during the 4th century nearly one-half of the Gothic tribes were Christians. We need not therefore necessarily feel suspicion, when we read of the Assyrians and the Persians, the Jews and the Idumæans: they may have been as well known to the Gleeman as to the Saxon monk who transcribed the manuscript. The chief interest however attaches to the mention of the various Gothic, Slavish, and Finnish races. In tracing their history, the 'Gleeman's Song' is the great link which connects the knowledge gained from Latin sources with the information gleaned from the Middle-Age chronicle. In many instances it furnishes the only means of penetrating the mystery which surrounds these races. There are tribes, still to be found between the Wolga and the Vistula, which we can identify with others named by the Gleeman, and thereby prove to have had a political existence fourteen hundred years ago, of whom hardly another trustworthy memorial can be found, till within the last two or three centuries. The helps which it affords us in unravelling the web of Gothic fiction are also most valuable, and may, if rightly taken advantage of, save us from much of that speculation in which German scholars have indulged so largely.

There are two other poems, which must have been composed before the Engle left the Continent, the "Battle of Fins-burgh," and the 'Tale of Beowulf.' The first of these is a mere fragment, and appears to have belonged to one of those historical songs which Tacitus ('Germ.,' 2) represents as the only literature of the ancient Germans. The other is chiefly taken up with the relation of two of Beowulf's adventures: the first against a monster called the 'Grendel;' the second against a terrific "worm," or "earthdrake." The poem has come down to us in a modernised form, and the mixture of Christian and heathen notions is sometimes singularly curious. For the most part, the nature of the subject, and the marked change that takes place in the rhythm, enable us to lay our finger on the very line where the interpolation begins. The following is one of the attempts to reconcile the old superstitions and the new creed:—

> "The grim stranger was Grendel hight—
> Mighty pacer of the March; who held the moors,
> Fen and fastness—land of the Fifel-kin.
>
> The hapless man long had kept it,
> Sithen his Maker him had doomed.
> On Cain's kin the slaughter avenged
> The eternal Lord,—for that he Abel slew;
> For joy'd he in that feud, but him out-drave
> His Maker, for the sin, far from mankind.
> Thence evil births all proceeded,
> Ettyns, and Elves and Orknees;
> So too the Giants, that with God fought
> A long throw—for it he paid them meed!"

The Goths seem to have peopled every solitude with a race of monsters called the Fifel-kin. The sea, the moor, the fen, the marsh, or desert track which surrounded the territory of every Gothic tribe, were their dwelling-place. The battle, by which Offa settled the marches between the Engle and the Swede, was fought at Fifel-door (see 'Gleeman's Song'), and Alfred, when he brings his hero from Troy, launches him on Fifel-stream, that is, the monster-deep. Ettyns were long remembered in our popular superstitions:—

> "They say the king of Portugal cannot sit at his meat, but the giants and *ettyns* will come to snatch it from him."
>
> Beaum. and Fl. *Knight of the Burning Pestle.*

Elves still live in our poetry; and genuine Gothic giants (notwithstanding the worthy monk tried hard to convert them into rebel angels) still terrify or amuse the nursery. The Orknees are probably the same monsters as the Orks of the Italian romancers.

Some of the oldest pieces of poetry, written after the removal of the Engle to this country, and now extant, are the songs of Cædmon. The circumstances which first called forth the talents of this poet are related by Bede; and as he must have known many of Cædmon's contemporaries, his account may be looked upon as a simple narrative of facts. Cædmon, it appears, was neatherd to the monastery of Whitby, then under the government of its first abbess, the celebrated Hild. One day at supper, as the harp was passing from hand to hand, and it came to his turn to amuse the company, he stole from the room in one of those fits of diffidence which so often overtake the sensitive poet. As he slept in the neathouse, some one, he thought, encouraged him to sing, and the song he composed, and which was next day repeated to an admiring audience, established his reputation as a poet, and gained him the patronage of the abbess. He became a monk: was looked upon as one who had received the gift of song from above; and on his death his body was enshrined, and valued as one of their most precious relics by the monks of Whitby.

Only six of Cædmon's poems have reached us. The subject of the first is the Creation; that of the second, the Temptation and Fall, to which is added, rather inartificially, a narrative of the events recorded in Genesis, to the offering of Isaac; the third relates the Exodus; the fourth, the story of Daniel; and the Torments of the Damned, and Christ's Harrowing of Hell, followed by his Ascension and Glory, are the subjects of the other two. Bede tells us that he also wrote on our Lord's Incarnation and his Passion, as also on the Advent of the Holy Ghost, and the teaching of the Apostles. What remains is equal in length to about one half of the 'Paradise Lost.' [CÆDMON, in BIOG. DIV.]

We have called the 'Battle of Fins-burgh' an historical poem: another poem of the same class was written on the death of Byrthnoth, who bravely fell in resisting one of the Danish inroads, A.D. 993. Works, now lost, were written in the 11th century, by Leofric, Hereward's chaplain, on the warriors of our early history; and the songs commemorative of Hereward's exploits, which Ingulf tells us were in his day so popular, were probably written by the same hand. There can be little doubt also that many of the Old-English romances, as 'Horn,' 'Havelok,' 'Bevis of Southampton,' 'Guy of Warwick,' &c., are mere adaptations of Anglo-Saxon poems. Occasionally the subject was taken from foreign sources, of which the 'Tale of Judith,' probably written in the 10th century, affords a splendid example. The 'Tale of Apollonius of Tyre' is in prose, and a mere translation from the Latin.

There are other songs preserved in our chronicles, and closely allied to those last mentioned, but which are much shorter, and partake more of the lyrical character. Among them may be enumerated the Brunanburgh war-song, Edgar's coronation song, the two songs which commemorate the death of this monarch, and the elegy written on the death of the Confessor. The first and last of these are among the noblest specimens of Anglo-Saxon poetry.

A great deal of Anglo-Saxon verse was written during the 11th century. One of the writers seems to have been called Deor. His name occurs in a poem which exhibits many difficulties of construction, and perhaps some blunders of transcription; but it may be gathered that he was *scop* or minstrel to the Danish princes who succeeded Knut, and he appears to have lost his place at court when the Confessor mounted the throne of England. The name of Cynewulf has also been extracted from certain poems found in the Exeter and Vercelli manuscripts. It was hid in a kind of riddle, similar in character to our modern acrostic. He was probably the compiler of the two manuscripts, and may have been the author of much of the poetry which they contain.

But the noblest relic of this period is the Psalter published by the University of Oxford, from a manuscript preserved in the 'Bibliothèque du Roi.' In the first part, each psalm has an Anglo-Saxon translation in prose; and also a preface giving some account of its history, general scope, and tendency. The translation often paraphrases the Latin, so as to show more clearly its doctrinal or prophetical meaning: but from the 50th Psalm, the translation is metrical, and though generally literal, exhibits many cases of glaring misconstruction. The prefaces also disappear, and the whole seems to be the work of a man very slenderly provided even with the rudiments of learning. This deficiency, however, may now be considered as amply compensated for by the high character of the poetry. Some of the psalms are translated with a terseness and also an elegance, which place the translation far above any of our modern versions, and there is occasionally a Miltonic sweep of language, that has not often been surpassed even in the choicest specimens of our sacred poetry.

A note in the manuscript informs us that a priest named Wulfwin Cada "wrote it with his own hand" (manu suâ conscripsit). We think it extremely probable that Wulfwin copied from some manuscript the prose version as far as it went, and then drew on his own resources. There are numberless instances of transcribers altering and continuing the work they were copying. Most of our manuscript chronicles were transcripts up to a certain date, and were then continued as original compositions. The verb *conscripsit* shows it was a compilation; and if Wulfwin had before him a metrical translation, he would hardly, with that passion for stately language so common among his countrymen, have postponed it to the prose version. To Wulfwin Cada we think may fairly be ascribed both the faults and the merits of the metrical translation.

Among the most important prose works of our Saxon literature must be ranked those extraordinary compilations which are commonly called (as if they constituted but one work) the 'Saxon Chronicle.' The earliest copy of a Saxon Chronicle now extant is the Plegmund Manuscript, in the library of Corpus Christi College, Cambridge. It is written, as Wanley observes, in the same hand to the year 891, and in hands equally ancient to the year 924. After that date it seems to have been continued and interpolated by various transcribers, whose notices of Christ Church, Canterbury, leave little doubt that the volume was once the property of that cathedral. As Plegmund was consecrated archbishop in 890, and died in 923, it has been inferred that the original text was compiled by his order, and continued from time to time under his direction. The internal evidence favours this supposition. The notices which it contains respecting the operations of Alfred and his immediate predecessors could hardly have been furnished by any but those who were present at them, and were probably the substance of conversations which had passed between the prelate and the king.

The next copy, in point of time, is the Dunstan manuscript in the British Museum. This is also a Canterbury manuscript, and appears to have belonged to St. Austin's Abbey. It is written throughout in the same hand, and ends in the year 977. As Dunstan was then archbishop, and as the handwriting resembles that of other manuscripts ascribed to him, he has been named with some degree of confidence as the transcriber. However this may be, it must have been written by a man of scholarlike attainment. We have only to compare the passages which relate to the period after Plegmund's death, with the corresponding passages in the Christ Church manuscript, to see at once its superiority. This is particularly striking in the poetical portions. The noble ode on the battle of Brunanburgh would have remained for ever mutilated, and in parts unintelligible, but for the copy preserved in the Dunstan Chronicle.

Besides these two chronicles, we have a Worcester, an Abingdon, another Canterbury Chronicle, and a fourth, which appears to have been written at Peterborough. It has been inferred (chiefly for reasons connected with the handwriting) that these were compiled respectively in the years 1016, 1048, 1058, and 1125. We have also divers transcripts and collations made by Lambarde, Junius Josselyn, and other antiquaries of the 16th and 17th centuries, some of which were evidently taken from manuscript authorities no longer extant. Josselyn appears to have had in his possession a second Peterborough Chronicle; and Lambarde's transcript in Trinity College, Dublin, is thought to have been made from an ancient manuscript which perished in the fatal fire that destroyed so many of our Cottonian treasures. The Plegmund, the Dunstan, the Abingdon, and the ancient chronicle transcribed by Lambarde, all began with Cæsar's invasion. The Worcester, Peterborough, and latest Canterbury manuscripts begin with a description of Britain, extracted chiefly from Bede and Orosius.

The antiquaries of the 16th and 17th centuries seem to have assumed that the Anglo-Saxon monasteries kept a regular record of contemporary events; and there are certainly grounds for believing that registers of a certain kind were really kept by them. Bede's 'History' (iv. 14) has been referred to in proof of this. He tells us, that in the year 681 a boy, who was an inmate of Selsey Abbey, was seized with the plague, which was then desolating the country. As the poor lad was lying on his bed, he was accosted by two angel-visitants, who bade him tell the frightened monks that the plague would spread no farther, that it been stayed by the prayers of Oswald, of whose death that very day was the anniversary. "Let them," said Saint Peter, for no less a person is the speaker, "search in their books (in suis codicibus) in which are recorded the deaths of deceased persons (defunctorum depositio), and they will find that on this day he was taken," &c. The abbot, we are told, believed the boy's words, and straightway went and searched in his chronicle (in Annali suo), and found that on that very day King Oswald had been slain, &c. Here reference seems to be made to some public register of the convent; and this register, or the earlier manuscript it was copied from, seems to have furnished materials for the Peterborough Chronicle.

"An. 642. Now was Oswald, king of the Northhymbre, slain," &c., "upon the Maser-field, on the day called the nones of August," &c.

The mention of the day on which an event occurred, is rare in our chronicles; it is therefore probable that we have here the very passage which the worthy monk was sent in search of.

That there were also public (or perhaps we might say national) registers, in which were recorded the accessions, &c. of the kings, we also gather from the same venerable historian. We are told ('Hist.' iii. 4), such was the horror excited by the cruelties of the Welshman Ceadwalla, and the apostacy of the Northumbrian kings, that "it was resolved upon by all who had to reckon the chronology of the kings (regum tempora computantibus) that the memory of the faithless kings should be blotted out, and the year assigned to the reign of the the king next following," &c.; and he elsewhere adds, with studied phraseology, "unanimo omnium consensu firmatum est," 'Hist.,' iii. 9. In the Chronicles we have the entry:—

"An. 634.———And Oswald also took to the kingdom of the Northhymbre, and he reigned ix. winters. They assigned him the *ninth*, on account of the heathenism which they practised who reigned the one year between him and Eadwine."

Here we find, within a century after Ida landed at Bamborough, a register kept of the Northumbrian kings, and general interest excited as to the entries made in it. From details mentioned by Bede, and which could only have been supplied by written documents, it is clear that these historical notices reached to the times of paganism. They must have been originally written in English, and with Runes, those ancient characters which were only partially given up when Christianity introduced the literature of Rome, and which occasionally make their appearance in our manuscripts to the end of the 11th century. [RUNES.] A too literal translation of these venerable documents, no doubt, introduced the many *Anglicisms* to be found in the works of Bede, and even of the Welshmen Nennius and Asser. On this ground only can we account for the intrusion into the pages of scholars like the first and last of these writers, of such phrases as "victoriam sumpsere" (sige namon, An.-Sax.), "loco funeris dominati sunt" (ahton wælstowe geweald, An.-Sax.), &c.

With these materials at hand, we may readily understand the course followed in the compilation of our early chronicles. Who were the parties that continued and interpolated these chronicles, is a question very difficult to answer satisfactorily. Archbishop Elfric, Saint Wulfstan, Hugh White the monk of Peterborough, and others, have been named, with more or less of confidence, by different critics. For our own parts, we could never resist a feeling, almost amounting to conviction, that the character of William was the work of the venerable Wulfstan. It begins thus:—

"An. 1087.———If any wish to know what manner of man he was, or what state he held, or of how many lands he was lord, then will we of him write, as we him knew, we that have waited on him (the him onlocodon), and otherwhiles in his court have wonned," &c.

There were few English churchmen at the close of William's reign who could put forth this claim to the confidence of their reader, and still fewer that could have drawn William's character with the freedom and at the same time with the Christian feeling that distinguishes the whole of this noble composition. Wulfstan was at that time the only English bishop; and when, after describing the cruelty and sternness of the king, he adds the prayer, "may the Almighty God show to his soul mercy, and grant him of his sins forgiveness!" who does not feel that the moral qualities of the writer were as eminent as the opportunities enjoyed or the talents that improved them?

Among Anglo-Saxon prose writers, we must not forget the name of Alfred. His chief works are translations from the Latin, and of these the most remarkable are his versions of Bede, Orosius, and Boethius. Certain verses of the last-named author he has also paraphrased in verse. Among what may be termed his original works, are his accounts of the voyages of the two Northmen Wulfstan and Ohthere, which were inserted in Hakluyt's collection, and have been the subject of so much comment and criticism.

Archbishop Wulfstan, better known by the name of Lupus, was a voluminous writer of homilies. He was translated from Worcester to York in 1002, and must be carefully distinguished from the Saint Wulfstan already mentioned. A still more celebrated divine was Ælfric, the great champion who led the English church in its resistance to the Romish innovations of the 11th century. As might have been expected, his authority was appealed to, and with powerful effect, by the friends of the Reformation. One of Archbishop Parker's works is entitled 'A Testimony of Antiquity, showing the ancient Faith of the Church of England, &c., being a Sermon translated out of Latin into English by Ælfric, abbot of St. Alban's,' &c. It required all the exertions of the new theological school founded by Lanfranc and Anselm to keep under the principles so deeply sown by Ælfric.

We will close this notice of Saxon literature by observing that the influence it has exercised upon the modern literature of the country has been much underrated. Without maintaining, as some authors have done, that Milton diligently studied Cædmon, yet we do not fear to assert that some favourite images, and even certain terms of expression, may be traced through our literature, century after century, from the pages of the Saxon *scop* to those of Spenser and of Shakspere. The mistaken criticism which some of these have called forth might afford matter for instructive comment; and serve in some measure to teach us the value of a literature which has been so much neglected.

SAXONS is the name of a branch of the German nation. Their name is derived by some from that of the Saces on the Indus, by others from *sex*, a weapon, probably of the nature of a stone axe, and by others it is traced to the work *sassen*, that is 'settled,' in contradistinction from those German tribes who led a sort of nomadic life. The earliest writers who mention the Saxons describe them as neighbours of the Danes, south of the Cimbrian Chersonesus. ('Geograph. Ravennas,' iv. 17.) Ptolemæus also speaks of the islands of the Saxons, which were probably the modern islands of Eiderstedt, Nordstrand, Wicking Harde, and Böking Harde. Orosius (vii. 32) says that they inhabited a marshy country which was almost inaccessible to strangers. Towards the south-west they seem at first not to have extended beyond the Elbe. Tacitus, though he speaks of the Angli and Varini, who must have been close neighbours to the Saxons, does not mention them.

The similarity of their language to that of the Persians and ancient Indians affords reason for believing that the Saxons were of eastern origin; but how and when they came to occupy the north-western extremity of Germany, are questions which history cannot answer. Thus much only is certain, that at first they occupied a great part of the country between the Elbe and the Cimbrian Chersonesus; but when, during the migration of the barbarians, the neighbouring tribes changed their countries and migrated towards the south, the Saxons likewise began to extend in the same direction, and at last we find them occupying the country between the Elbe, the Rhine, the Lippe, and the German Ocean. This extensive tract of land is called by Anglo-Saxon writers Old Saxony, to distinguish it from New Saxony, or England.

In the 3rd century the Saxons often landed on the coasts of England and France, and ravaged the maritime districts; but about the middle of the 5th century (449) a large body of Saxons and Angles established permanent settlements in this island. The Angles, however, seem to have prevailed in numbers or influence, for it was they that gave the name to their new country, Angel-land, Anglia (England), though it was sometimes called Saxonia Transmarina. The name Anglo-Saxons, which comprises both Angles and Saxons [ANGLES and ENGLAND, in GEOG. DIV.] was invented by later historians for the sake of convenience. The history of the Saxons, who settled in England, and here, together with the Angles, became the origin of a new population, henceforth forms part of the history of England.

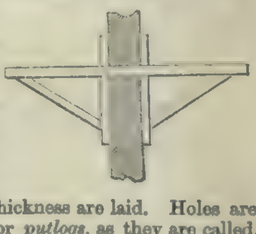
Those Saxons who remained in Germany conquered, about 530, conjointly with the Franks, the northern part of Thuringia as far as the little river Unstrut, but soon after gave up the eastern part of their conquest to a Slavonic tribe. The southernmost of the Saxons, about 550, became tributary to the Franks, to whom they paid an annual tribute of 500 cows. In proportion as the Saxons advanced towards the interior of Germany, and became better acquainted with the advantages of agriculture and the breeding of cattle, they gradually abandoned their former piratical mode of living, but remained nevertheless a spirited and warlike people.

Towards the close of the 7th century we find the Saxons divided into three great tribes, namely, the Ostfali on the western side of the Elbe, the Westfali in the country between the Rhine, Lippe, and Ems, and the Engeri in the centre, between the two former tribes, that is, on both banks of the Weser. Their hostile feeling towards the Franks was kindled into a war under Charles Martel, who conquered some Saxon districts on the northern banks of the Lippe, and made their inhabitants tributary. This, however, was only a prelude to the great and bloody wars which, with several interruptions, were carried on by Charlemagne from 772 till 803. During these wars many thousand Saxons fell in battle, and thousands were put to death because they refused to adopt Christianity. But they held out to the last, even after their chief Wittekind had submitted and become a Christian. The treaty of Selz on the Saale (803) at last terminated the war: the Saxons agreed to become Christians, and were put on a footing of equality with the Franks. Henceforth their history forms a part of that of the Carlovingian empire. To diffuse a knowledge of Christianity among them, and to establish the new religion more firmly, Charlemagne founded seven bishoprics, and from the places he appointed as the seats for these new ecclesiastical dignities, we may see the extent of country which they then occupied. The seats of the bishops were Osnabrück, Verden, Bremen, Paderborn, Minden, Hildesheim, and Münster.

SBIRRI, the name of a police force which existed in the Papal and other Italian states. They were not a military corps; they wore no uniform, and lived in their own houses; they received a small pay, and were furnished with arms. They were ready at any time of the day or night to rally at the summons of their captain, who was styled Bargello, for the purpose of tracing and arresting bad characters or suspected persons. Parties of them went their rounds in the towns at night. The Sbirri acted also as informers, and assumed various disguises for the purpose. They were placed under the orders of the respective governors of the towns and districts. This body of men fell at last into great disrepute: they were open to bribery, and often had a secret understanding with robbers and assassins. They were recruited from among bad characters, respited criminals, &c. In 1809 they were abolished in almost every part of Italy, and replaced by the Carabinieri, a regular military body, like the French gendarmes, who are found much more effective and trustworthy. Sbirri, however, are still employed in most of the Italian states, but generally under a materially improved institution.

SCABIES. [ITCH.]

SCAFFOLDING. A temporary wooden structure, by means of which the workmen employed in erecting the framework of a building are enabled to place the various materials in their definitive positions. Scaffoldings are either supported wholly, or in part, by the buildings to which they are attached; or they are made totally independent of those buildings, with points of support upon the ground. Sometimes the machinery for hoisting the building materials is placed upon the independent scaffoldings; at others, it is placed on the walls, or at the foot of the structure, or again, the materials may be carried up inclined roads formed in the scaffolding.



When scaffoldings are supported by the buildings they are designed to serve, they are usually formed by inserting cross-bearers in the walls (if the latter should be of a considerable thickness, and at some distance apart), which cross bearers project beyond the faces of the wall for a sufficient distance to allow the construction of a gangway for the workmen, and the extremities are strengthened by means of inclined struts. These cross-bearers are placed about 5 feet apart, horizontally; and in rows, vertically, about 6 feet apart; and upon them boards of 1¼ or 1½ inches in thickness are laid. Holes are left in the walls to receive the bearers, or *putlogs*, as they are called, and the feet of the struts are clipped by vertical ties, which clip also the putlogs, and thus form a complete frame acting on both sides of the wall; the whole of this framing is removed on the completion of the work, and the putlog-holes are filled in. When the walls are close together, the putlogs bear upon them without any struts, but the scaffolding in such cases rarely goes beyond the external face of the wall, so that the workmen are obliged to lay the materials "overhand." Chimney shafts are built in this manner, without framed scaffolding; many of the keeps of mediæval castles were built by means of framed projecting trusses; and in Viollet le Duc's 'Dictionnaire Raisonné de l'Architecture Française,' some curious illustrations of the manner in which the mediæval architects combined in the same scaffolding the functions of a working stage, and of an inclined road, will be found.

The ordinary scaffoldings used in the south of England, which are partially independent of the buildings, are composed of poles fixed in the ground at distances of about 9 feet from centre to centre; these poles are called the standards, and they are tied together by horizontal poles, or *ledgers*, at distances of about 6 feet vertically, as well as by raking braces. Upon the ledgers putlogs are laid at distances of about 4 or 5 feet, and with clear bearings, between the wall and the outer ledger, of from 3 feet 6 inches to 5 feet. The boards are laid upon the putlogs. Both the putlogs and boards are left loose, in order to allow materials to be hoisted without difficulty; but the standards, ledgers, and braces are firmly bound together by cords and wedges; nails or screws being, it is to be observed, rarely used in the construction of scaffolding. It is customary to strengthen some portions of the scaffolds thus formed, in order to provide for the reception of the hoisting machinery when stonework is used in conjunction with bricks; but of late years the scaffoldings of buildings in which stone is largely employed have been executed with framed baulk timber and constitute structures of great solidity. Detailed accounts of scaffolds of this description are to be found in the 'Transactions of the Institution of Civil Engineers,' in the 'Builder,' in the 'Nouvelles Annales de Construction,' in the 'Annales des Ponts et Chaussées,' &c., in Rondelet's 'Art de Batir,' Kraft's 'l'Art de la Charpente,' Perronnet's 'Nouvelle Architecture Hydraulique,' Fontana's 'Templum Vaticanum,' &c. Descriptions of scaffoldings which have been made to serve at the same time as centres, or supports for parts of the work of the permanent structure, are to be found in those works. In Foster's 'Bauzeitung' for 1854 there is a very good account of the suspended scaffolding used in the reconstruction of the Pont Neuf, to which it is desirable to call attention. See also Emy's 'Traité de la Charpenterie.'

The scaffoldings which are erected independently of the buildings, throughout, are in point of fact timber structures of a very elaborate description, and they have to resist not only the various actions produced by the movements of the materials and of the workmen, but also those produced by the wind, acting as the latter frequently does with a great leverage. It becomes essential, under these circumstances, to frame and brace the whole system with extreme care; and, should the scaffolding have to remain a long time in place, precautions must be taken to guard against any decay of the wood. This, of course, would be the most likely to commence in the portions of the scaffolding built into the ground, or in those directly exposed to the action of the rain; the scarf or tenon joints also are very likely in these structures, which always have a degree of flexibility, to give access to the atmospheric moisture, and thus to rot. It is only in buildings of the greatest importance, or of a very peculiar nature, that scaffoldings entirely independent of the walls are used; for their construction really requires the erection of a timber frame on each side of the wall, and is consequently a very costly operation. The scaffolds used for raising the obelisks of Luxor, and in the Piazza in front of St. Peter's at Rome, are amongst the most remarkable works of this kind yet executed. See Fontana and Emy.

SCAGLIOLA (from the Italian *scaglia*, a scale or shell) is an *incrustation* of artificial composition which is applied to columns, and produces the most perfect imitation of marble, from which it can hardly be distinguished either by the eye or the touch, as it takes an equally high polish and feels equally hard and cold. Scagliola has long been in use in Italy, where, according to Lanzi, it was invented by Guido Fassi of Carpi (1584-1649), and where it was afterwards much used for Florentine or inlay-work of the kind called *a commesso*. It was not introduced into this country before the latter half of the last century, and the earliest application of it was in the columns of the Pantheon in Oxford-street, London, built by James Wyatt. Since that time, it has been brought into more general use, the manufacture of it has been considerably improved, and it can be executed at a comparatively moderate cost. In fact, it has to a great extent superseded the use of coloured marbles for columns and other interior decorations. It is far less costly than any kind of variegated marble, though too expensive to be brought into ordinary use on every occasion, and it answers the purpose of the real material not only as regards appearance and effect, but durability also, since it will last quite as long as any other part of the interior of a building. There is besides the advantage attending it, that columns incrusted with scagliola may be made of wood and hollow, or else filled with a plaster core, and consequently do not require that support in the floor beneath them, which would be necessary if solid marble shafts were employed; or if required to support a bearing above them, the columns may be of brick or ordinary stone, and afterwards coated with scagliola. Nor is the use of this composition confined to columns and pilasters only, for it may be and indeed is applied to other ornamental purposes, for table-slabs, pedestal-stands, dados of rooms, borders of floors, &c.

The composition or cement itself is prepared from the purest gypsum, which is first broken into small pieces, and after being calcined is reduced to powder. It is then passed through a fine sieve, and mixed with Flanders glue, isinglass, &c. In this state it is mixed up with colouring matter of the hue required; and as it is generally employed for the imitation of variegated or veined marbles (all coloured ones being more or less so), as many different colours and shades of the same colour must be mixed up separately as there are in the kind of marble to be imitated. Thus prepared, the composition is applied to columns or other surface intended to receive it, and which has a rough coating of lime and hair. The different colours are laid on and mixed by the workman, and consequently much depends upon his skill and taste in regard to the exactness of the imitation or the beauty of the veining and streaking, which is done in the floating, as it is termed, or laying on the cement. The next operation is to prepare the surface for polishing, by rubbing it with pumice-stone and cleansing it with a wet sponge. The polish is then given by rubbing it again, first with tripoli and charcoal on a piece of fine linen, secondly with felt dipped in tripoli and oil, and lastly with oil alone. By this means a durable lustre is obtained equal to that of the finest and most highly polished marble. By means of scagliola, not only may the costliest and rarest stones, porphyry, verde antico, giallo antico, &c. be successfully imitated but any combination of colours may be produced; for instance, purple, or emerald green, streaked with gold, Siena veined with purple, or any other splendid caprice that fancy may dictate.

SCALD. [Burns and Scalds.]

SCALD, properly SKA'LLD, is an ancient Scandinavian word which signifies poet, as skálldmär or skálldkona signifies a poetess. The name is, therefore, sometimes applied to the Scandinavian poets in general; but it belonged more especially to that class of poets who celebrated in their songs the exploits of heroes. The Scalds were thus not merely poets, but also the historians of their nation. When Snorri Sturluson, the last and most celebrated of the Scalds (1178—1241), states that the Scalds indeed always praised their contemporary heroes most, but never attributed to them any fictitious deed, we must infer that the creative powers of these poets had no scope, at least as far as contemporaneous history was concerned. The form and mode of diction were thus the only parts in which they displayed their poetic powers; and how they availed themselves of this right is clear from the numerous specimens of Scaldic poetry still extant: they are full of the boldest and most extraordinary imagery, whence they are frequently very obscure and almost unintelligible.

Scaldic poetry is almost the only source from which we derive our knowledge of the ancient history of the north of Europe. A considerable portion of it goes back to the remotest antiquity, and contains only mythological legends; while another portion, in the form of poetry, contains historical accounts of contemporary events. Such poetical histories, very different from the rhymed chronicles of other nations, continued to be written down to the middle of the 13th century. The Scalds were generally in the service of a chief or king, whom they accompanied on his expeditions in the capacity of historiographers; and it was the pride of the chieftains to obtain such Scalds as possessed most ability and learning. Their services were richly rewarded by the heroes whose praise they sang.

We still possess a very long list of Scalds, among whom are persons of the highest rank, and even kings. The most distinguished, however, were those of Iceland, and it is to these that we are indebted for the collection of ancient poetical traditions known under the name of the Eddas. Those which are more historical are known as Sagas, though in many cases these are mythical or legendary, as in the saga of Ragnar Lodbrok, and the 'Heldensage von Völund' (our Wayland Smith). Between the time when the death-song of Ragnar Lodbrok was composed (about the end of the 8th century) and that of Snorri Sturluson [Biog. Div., where, by mistake, it is printed Sturulson], we have the names of upwards of two hundred Scalds, of whom the more eminent were, Egil Skallagrimson, who wrote in praise of Erik Blödaxe, king of Norway; Einar Skaloglam, on the deeds of Hakon Jarl; Eynind Skaldaspillar, one of the best of the race, whose 'Harkinamal' is also an eulogism on Hakon; Olaf Hvitaskald, said to be the author of a part of the prose 'Edda;' and Sturla Thordarson, the writer of the 'Rafnsmal;' but none of them possess the vigour and freshness of the earlier productions, though sufficiently curious as presenting pictures of the life and manners of the times. With the introduction of Christianity the poetic power was devoted to the celebration of saints and miracles, and the zeal of the priests succeeded not only in suppressing the inspiration of the poets, but in destroying the existing specimens, so that only in Iceland, where the priesthood was selected from the natives, and no foreign influence interfered with the old national literature, have any relics been preserved. Compare 'Fundgruben des Nordens,' by Legis; John Olafsen, 'Om Nordens gamle Digtekonst, Grundregler, Versarter, Sprog og Fóredrags mode,' Copenhagen, 1786; and the article Snorri Sturluson, in Biog. Div.

SCALE (Mathematics). A scale is any line drawn upon wood or other solid substance, and divided into parts, equal or unequal, the lengths of which may be taken off by the compasses, and transferred to paper, in aid of any geometrical construction. The manner in which the scale is divided depends of course upon the nature of the algebraical or trigonometrical expression the values of which are to be represented. When the subdivisions of a scale are equal, any of the methods noticed in Graduation may be employed to obtain them; but in other cases, and indeed in the preceding one, it is usual to form scales by copying from an original which is carefully made in the first instance.

The most simple of all scales is that in which the subdivisions are all equal, or, as it is called, a scale of equal parts. Such a scale is not only the most easily constructed, but may be considered as containing all other scales. For example, suppose it required to lay down very accurately an angle of 25°. It appears [Chord] that if the radius contain 500 equal parts, the chord of 25° contains 216 such parts and $\frac{4}{10}$ths of a part. With a good scale of equal parts, and 500 of them taken as a radius, the angle may be laid down, if required, much more correctly than by a common scale of chords. [Protractor.] The largest table of chords which is laid down on common scales has a radius of 3 inches, the 500th part of which, or about the 167th of an inch, is a very small length; and it is difficult to trust any scale so far without verification, except the scale of equal parts. In the latter species, one part may be tried against another, and any one may for himself very soon ascertain whether there be any perceptible error.

In all the most accurate species of drawing, it is better to rely on tables and a really good scale of equal parts than on any of the common scales, though the latter are generally very good, and will do abundantly well for ordinary purposes.

Long scales of equal parts are made with different subdivisions, ranging from the 30th part of an inch to the 50th. If the substance of the scale be ivory, an inch will very well bear division into 60 parts, but 50 is more convenient for decimal calculation. A common ivory scale, of a rectangular form, such as is usually found in cases of drawing instruments, if it have no trigonometrical lines laid down, usually contains the following scales of equal parts:—

1. The quarter of an inch divided into 10 equal parts, each of which is again subdivided into 10 equal parts by a Diagonal Scale. There are commonly two diagonal scales, one at each end of the scale of quarters, the one on the left dividing the 8th of an inch into 100 parts, and the one on the right the quarter. It will easily be seen that the 400th of an inch is a uselessly small quantity, even when the lines are drawn on ivory.

2. A set of scales in which the inch is severally divided into 30, 35, 40, 45, 50, and 60 equal parts: 10 of these parts make, in each case, one of the larger subdivisions of the scale, and one larger division is also divided into 12 equal parts; so that, when the larger division is made to represent a foot, feet and inches may be easily laid down.

3. A set of scales in which the larger divisions are $\frac{1}{2}$, $\frac{2}{5}$, $\frac{3}{4}$, $\frac{1}{3}$, $\frac{5}{8}$, $\frac{2}{3}$, $\frac{7}{8}$, and $\frac{3}{8}$ of an inch. The larger division is, as before, divided both into 10 and 12 parts.

When trigonometrical lines are laid down they are usually one or two scales of *chords*, the radius of each of which is found by its chord of 60 degrees; a scale of *rumbs*, which is nothing more than a scale of chords, the angular unit being, not a degree, but a point of the compass; a scale of sines, with one of secants sometimes added; a scale of tangents, and of semitangents, the latter being really the same scale as the former, but marked with double angles, semitangent being a technical term, not for the half of a tangent, but for the tangent of half an angle. We shall have something more to say of these lines under Sector. In Gunter's scale, as it is called, which is a scale of 2 feet in length, used in navigation, there are also scales of logarithms, of numbers, sines, tangents, &c., and also a scale of meridional parts [Rumb Line]; of these logarithmic scales we shall have to speak more particularly under Sliding Rule.

SCALE (Music). A great deal has been written on this subject, by mathematicians, by musicians, and by those who combine both characters; but, from various circumstances, hardly anything which is accessible to the young arithmetician wishing for something which may really be a help to him in his musical studies. The Greek scale [Music; Tetrachord], the only fruitless subject of inquiry out of all that is Greek, has exhausted the learning, science, and ingenuity of the best writers, with no result but this, that over-refinements of theory are found either to have hindered practical excellence, or to have arisen out of the want of it; most likely the latter. The learning however which it was necessary to apply to the explanation of the Greek writers, has made it usual to write on this subject more profoundly than on others of the same difficulty: it is our object in the present article to explain the musical scale, if possible, more simply, and in its simplest parts: leaving to the article Temperament such considerations as, arising out of the present article, are required by those who would understand the higher practical details of the subject.

The object of music being to please the ear, or the mind through the ear, there is no test of excellence nor criterion of fitness, in any one detail, except the opinion of the best judges. This seems to assume the question, for the best judges can only be described as those who best know what is good music. This circle cannot be avoided, either in speaking of music or any other of the fine arts; to taste we must appeal, but not to the taste of every one. All we have here to do with this is to remark, that the mathematical considerations employed in an article like the present are not to be considered as placing the musical scale upon a mathematical basis, but simply as showing that there is something like an explanation of those rules which derive their authority, not from the mathematical system which embodies them, but from the sanction of the majority of cultivated ears. Those things which are agreeable in practice are found to be in certain mathematical relations to one another which make the theory of the musical scale simple and interesting: but had it been otherwise, we should have left mathematical simplicity, and preferred a more pleasing complexity.

The sounds which are agreeable to the ear are found to be those which are the consequence of vibrations of equal duration following one another: and the pitch of the note depends on the rapidity of vibration only. [Acoustics.] The note called A, for instance, sounded at the same time on a harp, a flute, and a horn, presents three different characters, three different intensities, but only one species of vibration as to the time of lasting. If the first instrument communicate 430 vibrations in a second to the air, so does the second instrument, and also the third. With the difference of intensity or loudness, and with the difference of character, the twang of the harp, or the tone of the horn, we have nothing to do in considering the place of the note they sound in the scale; a cultivated ear discovers that they sound the same note, and a mathematician knows that they severally communicate to the air the same number of vibrations per second.

Let us then suppose a string to be mounted, and stretched at both ends, or, better still perhaps, suspended vertically [*] by one end, and bearing a weight at the other. If this string be then set in vibration by the finger or by the bow of a violin, a musical (that is, a pleasant) sound is produced, if the string be not too long, nor stretched by too small a weight. With the phenomena of vibration, as connected with the length, material, and stretching weight of the string, we have here nothing to do [Cord] except to remark,—1, That the ear observes that, material and tension remaining the same, the longer the string the lower the tone, and *vice versâ*. 2, That the mathematician knows that, *cæteris paribus*, the longer the string the fewer the number of vibrations in a given time, in inverse proportion to the length. Thus if a certain string, stretched by a certain weight, give 100 vibrations per second, a string of half the length, stretched by the same weight, will give 200 vibrations per second. If a vibration mean a double motion of the string, once backwards and once forwards, the effects begin to be musical soon after the string is short enough, or stretched enough, to give 30 vibrations per second.

The number of musical tones is, theoretically, infinite: that is, between any two tones as many different tones as we please can be interposed, no one of which is so high as the higher, nor so low as the lower. Highness and lowness of tone are terms which are purely relative, and refer to an effect upon the ear which does not admit of definition; common terms usually distinguish only extreme cases; thus, a tone disagreeably high is a squeak, and one disagreeably low is a growl. There is no absolute reason why we should call the former high and the latter low, rather than the contrary; and in fact the earlier Greeks (naming them after the parts of the throat in which they thought they were produced) called the squeaking sounds low, and the growling ones high. But while we endeavour to separate names from things, we must not forget that there is much which all men acknowledge of real connexion between the associations which accompany sounds and those derived from other sensible phenomena. For instance, it would be impossible to persuade any one, that if light and darkness were to be imitated by musical tones, the light ought to be represented by low notes, and the darkness by high notes: and a composer who should accompany words expressive of transition from darkness to light by a marked descent from the higher part of the scale to the lower, would be thought to mean irony or burlesque. No satisfactory explanation has ever come to our knowledge as to what associations are awakened by the lower notes of the scale which connect them with darkness; but that this connexion does exist is certain.

Taking such a string or monochord (*single string*) as above described, it is immediately found that any alteration of its length produces some alteration of the tone. If the change be very slight, a dull or unpractised ear may not readily perceive it; but let the alteration be carried a little further, and there can be no difficulty. Such tones, near to one another, when sounded together, have a disagreeable and jarring effect, accompanied by beats [Acoustics]; but when the second string has been considerably shortened (say that this is done gradually), the disagreeable effect ceases almost at once, and at the moment when the shortened string is to the longer one as five to six. Two sounds are then heard which *harmonise* together, and on their joint effect the ear dwells with pleasure until it becomes monotonous (this very common word is itself derived, as to its common signification here used, from the wearying effect of the same tone, or set of tones, long continued). In the mean while, and during the shortening of the string, the joint effect, though always disagreeable, is not equally so throughout; and there is one place in particular where the effect, though not agreeable to the beginner, is bearable for a little while, and highly agreeable to the practised ear, which knows that full compensation is at hand in what is called the resolution of the discord, or transition to a more harmonious combination in a manner which seems peculiarly natural. This intermediate and more tolerable phase of sound takes place when the shortened string is to the other as eight to nine. Moreover, it may be observed that this last combination, hardly bearable, is rendered perfectly so if the two tones, instead of being sounded together, are made to follow each other in succession, no matter how rapidly. In both these cases the student will observe that the proportion of the lengths of the strings is that of some small numbers, five to six, and eight to nine. And it is matter of experiment, that the more simple the proportions of the lengths of two strings (stretched by the same weight), the more useful the combination in music: it is usual to say, the more agreeable sounded by itself; but to this we cannot subscribe, as we believe that to most ears the more complicated combination of a *third* (presently to be described) is more agreeable than the less complicated one of a *fifth*.

Instead of speaking of the lengths of the strings, we may pass to the relative numbers of vibrations in a second, which are inversely as the lengths. Thus, two strings of ten and seven feet, stretched by the same weight, vibrate so that the one of ten feet makes seven vibrations while that of seven feet makes ten.

---

[*] Woolhouse 'On Musical Intervals,' p. 64. The author repeated the experiments of Fischer [Acoustics] and found a monochord thus constructed better than the common one for the purpose. His result was that A (the second space of the treble clef) made 424 vibrations in one second.

We now proceed to consider the most simple combinations; and first, that of two to one. Let the second string be half the first, or make two vibrations while the first makes one: there is then not only a joint effect which is agreeable, but a peculiar sameness of the two notes, insomuch that two instruments made to play together in such manner that the notes of the second shall always be of twice as many vibrations as the simultaneous notes of the first, would be universally admitted to be playing the same air, with no more difference than of that sort which is heard when a man and a boy attempt to sing the same air together. This perfect sameness, for so it will be called, though the two instruments never sound the same tone together, admits of no explanation; for though the ratio of the simultaneous vibrations is the simplest possible (two to one), there is no perceptible reason why, because simple ratios generally give harmonious combinations, the most simple of all should produce an absolute feeling of identity of character in the two tones. To this circumstance however we owe the most material simplification of the musical scale; for let it be settled, for instance, what strings give agreeable notes between those of 20 and 10 feet long, and division by two will give all the strings which can be admitted between those of 10 and 5 feet; thus, if it be proper to admit a string of eight feet in the former set, one of four feet must also take its place in the latter.

Again, it is observed that the relative effect of two tones is always the same as those of other two, when the numbers of vibrations made in a given time in the first pair are *in the same proportion* as the corresponding numbers in the second pair. Thus, suppose that in a given time the numbers of vibrations made by four strings are 12, 18, 40, and 60. Then, since we see that

$$12 : 18 : : 40 : 60 \text{ or } \tfrac{18}{12} = \tfrac{60}{40}$$

we may say that, according as the first and second sounded together are pleasant or unpleasant, so are the third and fourth; also if an air beginning on the first string require an immediate transition to the second, then the same air begun on the third string will require an immediate transition to the fourth.

A *musical interval*, then, is given when the fraction which expresses the proportion of the vibrations of its two notes in a given time is given. By the interval $\frac{3}{2}$ we mean that of two notes, the higher of which makes three vibrations while the lower makes two. Thus, if 18, 23, and 30 be the numbers of vibrations made by three strings in the same time, and we wish to find a fourth note which is as much above the third as the second is above the first, we must not make a string of 35 vibrations in the same time (as the beginner might do), that is, not one of $30 + 23 - 18$, but one of $30 \times \frac{23}{18}$, or $38\frac{1}{3}$ vibrations in the same time.

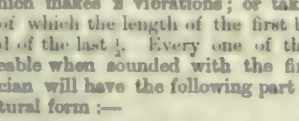
Let us now take a string, and call the note sounded by it C, and let the string of twice as many vibrations (or half its length) have the same name, with a difference (for the reason above given); call it C^1. Let us now seek for the simplest fractions which lie between 1 and 2. Take the numbers up to 6 (the ear does not so well agree with 7 and all higher prime numbers, why of course cannot be told, but simplicity must end somewhere, and, by the constitution of the ear, ratios in which 7 and higher primes occur are not agreeable), and form every fraction out of them which lies between 1 and 2; we have then—

$$\tfrac{3}{2},\ \tfrac{4}{3},\ \tfrac{5}{3},\ \tfrac{5}{4},\ (\tfrac{6}{4} = \tfrac{3}{2}),\ \tfrac{6}{5}$$

Put these down, with 1 and 2, in order of magnitude, and we have

$$1 \quad \tfrac{6}{5} \quad \tfrac{5}{4} \quad \tfrac{4}{3} \quad \tfrac{3}{2} \quad \tfrac{5}{3} \quad 2$$

Take such a set of strings that while the first makes one vibration the second makes $\frac{6}{5}$ of a vibration, the third $\frac{5}{4}$ of a vibration, and so on up to the last, which makes 2 vibrations; or take a set of strings equally stretched, of which the length of the first being 1, that of the second is $\frac{5}{6}$, &c., and of the last $\frac{1}{2}$. Every one of the notes thus produced will be agreeable when sounded with the first, and if the first sound C, the musician will have the following part of the scale before him in its most natural form:—



These intervals have the following names; why, will presently be seen,—

$\frac{6}{5}$ minor third.
$\frac{5}{4}$ major third.
$\frac{4}{3}$ fourth.
$\frac{3}{2}$ fifth.
$\frac{5}{3}$ major sixth.
2 octave or eighth.

We have not yet, however, got a sufficiently agreeable scale, and the reasons why the ear will not be contented with the preceding most simple concords, must be derived from observation, from which it appears—

1. That a frequent repetition of sounds very near to one another is not pleasing to the uncultivated ear. Now the interval from the minor to the major third is as follows: the first makes $\frac{6}{5}$ of a vibration while the second makes $\frac{5}{4}$, or the first makes 1 vibration while the second makes $\frac{5}{4} \times \frac{5}{6}$, or $\frac{25}{24}$. This is much too near to a unison for continual repetition.

2. That a frequent repetition of sounds too far from each other is not pleasing to the ear, after a little cultivation. If we look at the intervals from the fourth to the fifth, and from the fifth to the sixth, we find $\frac{9}{8}$ and $\frac{10}{9}$ for their representatives, while from the fundamental note to the minor third, and also from the sixth to the octave, the interval is $\frac{6}{5}$, much larger than the preceding intervals.

Both these defects, as must easily be seen arithmetically, and as the ear finds out for itself, may be remedied by inserting a note between C and E in place of E♭, which shall make a better division of the interval C E, and by placing an additional note between A and C^1. But how are we to choose these additional notes? If we cannot have any more very simple consonances with the fundamental note, we must take those tones which make the simplest consonances with other notes, and the more they make the better. We have already a repetition of some consonances; for instance,

Interval FC^1 is $2 \div \frac{4}{3} = \frac{3}{2}$, or a fifth.
Interval GC^1 is $2 \div \frac{3}{2} = \frac{4}{3}$, or a fourth.
Interval FA is $\frac{5}{3} \div \frac{4}{3} = \frac{5}{4}$, or a major third.

Now since $\frac{9}{8} \times \frac{4}{3} = \frac{3}{2}$, we see that a note $\frac{9}{8}$, or one which makes 9 vibrations while the fundamental note C makes 8, will be a fourth below G, and $\frac{9}{8}$ divides C and E well, the three notes 1, $\frac{9}{8}$, $\frac{5}{4}$, giving the intervals $\frac{9}{8}$, $\frac{10}{9}$, already found in another part of the scale. This note is D. Again, observe the interval from E to F, or $\frac{16}{15}$, and take a fifth above E, or $\frac{5}{4} \times \frac{3}{2}$ or $\frac{15}{8}$: this fraction falls between $\frac{5}{3}$ and 2, and looking at the intervals of $\frac{5}{3}$, $\frac{15}{8}$, and 2, we find $\frac{9}{8}$ and $\frac{16}{15}$, both of them intervals already found. This note $\frac{15}{8}$, or which makes 15 vibrations while the fundamental note makes 8, is B, and the usual scale of civilised nations, called the *diatonic* scale, is now complete in the following—

C	D	E	F	G	A	B	C^1
1	$\frac{9}{8}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{15}{8}$	2

This diatonic scale seems then to be the scale of the simplest concords of the fundamental note, with one alteration on account of the too great proximity of two concordant notes, and one interpolation on account of the too great distance of two others. If we examine all its intervals, we shall find both repetition and variety as follows (C D standing for the interval from C to D, &c.), some new appellations being added:

CD = FG = AB . . . = $\frac{9}{8}$ (major tone).
DE = GA . . . . = $\frac{10}{9}$ (minor tone, $\frac{80}{81}$ of major).
EF = BC^1 . . . . = $\frac{16}{15}$ (diatonic semitone).
CE = FA = GB . . . = $\frac{5}{4}$ (major third).
EG = AC^1 . . . . = $\frac{6}{5}$ (minor third).
DF . . . . . . = $\frac{32}{27}$ ($\frac{80}{81}$ of minor third).
CF = DG = EA = GC^1 . = $\frac{4}{3}$ (fourth).
FB . . . . . . = $\frac{45}{32}$ (flattened fifth).*
CG = EB = FC^1 . . = $\frac{3}{2}$ (fifth).
DA . . . . . . = $\frac{40}{27}$ ($\frac{80}{81}$ of fifth).
CA = DB . . . . = $\frac{5}{3}$ (sixth).
EC^1 . . . . . . = $\frac{8}{5}$ (minor sixth).
CB . . . . . = $\frac{15}{8}$ (seventh).*
DC^1 . . . . . . = $\frac{16}{9}$ (flat seventh).†
CC^1 . . . . . = $\frac{2}{1}$ (octave).

We observe here the consonances mentioned before, two inharmonious intervals, a new species of consonance (the flat seventh) standing as it were between the more perfect consonances and the others, and new varieties of a tone, of a minor third, and of a fifth, differing from those already described, and flatter by the interval $\frac{81}{80}$. This interval is called a *comma*, and though the ear can distinguish a difference between the tones of two strings, one of which vibrates 81 times while the other vibrates 80, yet the difference is so slight as to produce no prejudicial effect. With regard to the comparatively harmonious character of the flat seventh, observe that $\frac{16}{9}$ is very nearly equal to $\frac{7}{4}$, differing only by the interval $\frac{64}{63}$.

We have also the diatonic semitone, $\frac{16}{15}$, which is incorrectly named, since, if beginning with 1, we repeat the interval of a semitone twice, we have $\frac{16}{15} \times \frac{16}{15}$, or $\frac{256}{225}$, which is very near to $\frac{8}{7}$, sharper (that is, higher, as flatter means lower) than a major tone by the interval $\frac{89}{88}$ and than a minor tone by $\frac{43}{42}$, very nearly.

We shall presently resume the diatonic scale, but we now proceed to mention two varieties of it. It seems to have been offensive to the ears of rude nations to hear any semitones at all. If we deprive the diatonic scale of F and B, the notes which make semitones with their nearest neighbours, we have C, D, E, G, A, C, for all the sounds which remain in the octave. This unfinished scale, as we should call it, is the original scale of the Chinese, Avans, Hindus, and Eastern Islands, the northern nations of Europe, &c. It is the well-known scale of the old Scotch and Irish music; it is said to have been found in Wales and Cornwall, in various parts of Africa, and even in old Italian music. The Chinese, who never change, have preserved it in absolute perfection, though the modern form of most ancient airs in other countries has been relaxed. We copy the notes of a Chinese air given by Laborde :—

---

* An inharmonious interval, when the notes are sounded together.

† Decidedly more harmonious than the seventh.

D C C G A G G C C A G E D C C G A G A A C E C A G G C C A G E C C E D A C

It will be observed that F and B never occur. An almost perfect specimen of this scale occurs in the Scotch air 'The Campbells are coming.' The effect of the scale may be tried by playing *ad libitum* on the black keys of a piano-forte.

The other scale which we have here to mention is that known by the name of the *minor* scale, the common diatonic scale being for distinction called *major*. It may easily be observed that the intervals of the minor third and minor sixth have a sad, or at least plaintive effect, as compared with the major third and major sixth. No explanation can be given of this: perhaps the effect of musical intervals is governed in some degree by associations derived from the human voice in speaking. All persons, except perhaps schoolboys reading what they do not understand nor care about, are constantly, whether they know it or not, varying the tone in which they speak, and making intervals which are very nearly musically correct: and the effect of sorrow, regret, fatigue, &c., is to make those intervals minor. Any person of a quick musical ear who will watch the method of saying the simple words "I cannot," pronounced as a determination of the will, and compare it with the same when it is an expression of regret for want of power, will almost always find such an interval as C F or C^1 G in the first, and C E♭ or C^1 A in the second; if this be so, it is not surprising that a scale in which minor intervals occupy conspicuous places which in the other scale are occupied by major intervals, should produce those associations which have been alluded to. This is a conjecture merely, for after all nature will take the liberty in art, as in science, of concealing her operations. But this much is certain, first, that the minor scale is more plaintive than the major, and secondly, that all musical composers are acquainted with the fact, from the African women who sung of Mungo Park, "Let us pity the white man, no mother has he to bring him milk, no wife to grind his corn," up to the composer of 'Der Freischütz,' with all the power of cultivation and the memory of centuries of art. The change from the minor to the major scale is perhaps the most effective of musical resources, certainly the most powerful of those which are easily understood by ears of the ordinary degree of cultivation. Take as an instance the music of the following words from Oberon :—

Oh-Araby,-blest-Ara-by, my own, my native-land,
Methought I-crossed-the dark-blue sea, and touched a-gain-thy strand;
And-there I saw my-father's house, &c.

The intervals with which the voice passes over the hyphens in the first two lines are minor, but in the third line a modulation is made into a major scale, and the composer has skilfully taken care to produce a strong result of the new scale in the first two syllables: the effect of the change is strikingly appropriate.

What is the minor scale? This question has been differently answered by different writers on the theory of music, who severally contend for one or another scale as *the true scale*. For ourselves, we are no believers in true and orthodox scales, or rather we hold every scale to have that character which has been used by good composers and approved by good hearers. It seems to have been thought that because there is one diatonic major scale, by universal consent, therefore there must be one lawful diatonic minor scale: just as well might it be said, that because the iambic trimeter is the one metre of Greek tragic dialogue, there must also be some one other metre, and that one only, in the choruses. Fortunately however the scholar knows, what the musician ought to know, that no one metre is dictated by any absolute law of taste, and teaches that the best tragedians must be the guide, because of the universal approval which has been conceded to their writings. Taking the same sort of guide, we find in the writings of musicians (the unknown authors of national airs, writers of very high authority, included) one major scale and several minor scales; a thing not more atrociously wrong in itself than the one metre of dialogue, and the variety of chorus metres, of the Greeks. And if, moreover, we take the mathematical theory of the scale, we shall find several with equal claims on the score of simplicity of consonances.

Return to the fundamental note C and its consonances, namely—

C	E♭	E	F	G	A	C^1
1	$\frac{6}{5}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	2

Instead of throwing out E♭ as too near to E, let it be the latter which we reject; if we finish this with the D and B of the diatonic scale, we have what is called the *common* ascending minor scale, the commonness of which we cannot deny upon data, though it strikes us that others are as common, if not more so.

(1)	C	D	E♭	F	G	A	B	C^1
	1	$\frac{9}{8}$	$\frac{6}{5}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{15}{8}$	2

The ear will not very quickly acknowledge this as a minor scale in descent, and for the obvious reason that in going from C^1 to C there is no distinction between this scale and the major scale till we come to E♭; though in the ascent the minor interval occurs early. To remedy this, A and B are both lowered a semitone, or the A is made A♭, a fourth to E♭, and the B is made B♭, a fifth to E♭, which gives

(2)	C	D	E♭	F	G	A♭	B♭	C^1
	1	$\frac{9}{8}$	$\frac{6}{5}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{8}{5}$	$\frac{9}{5}$	2

and this scale reversed is called the common mode of descending the minor scale; but as we also find it used in ascending, we put it down as a second minor scale, both for ascent and descent, observing also that (1) may be, and is, used in descent. Again, suppose we retain the B of the original scale, and lower the A, we have then

(3)	C	D	E♭	F	G	A♭	B	C
	1	$\frac{9}{8}$	$\frac{6}{5}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{8}{5}$	$\frac{15}{8}$	2

a wild and pleasing scale, both in ascent and descent, and employed too, in spite of the wide interval between A♭ and B. Its harmonies, technically speaking, are easier and more natural than those of the common scale, and Schneider ('Elements of Harmony') makes it the principal minor scale, treating all others as incidental deviations: the English translator of Schneider contends for its absolute truth, and asks (justly enough) which scale a composer would take who was converting the air of 'Robin Adair' into the minor key (the original air having the notes G A B C D E) namely, G A B C D E♭, or G A♭ B C D E♭? There can be no doubt that the latter would be preferable, but we might add, that if the composer were required to make two variations in the minor key, he would probably choose scale (1) for his other case. The following minor scales are used, and are agreeable :—

(4)	C	D♭	E	F	G	A♭	B	C
	1	$\frac{16}{15}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{8}{5}$	$\frac{15}{8}$	2
(5)	C	D	E♭	F	G	A	B♭	C
	1	$\frac{9}{8}$	$\frac{6}{5}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{9}{5}$	2

Of all these minor keys, we prefer (3). For an instance of the use of it, take the first part of the air "Charlie is my darling," the notes of which run thus, C D E♭ F G C^1 G A♭ C^1 A♭ G C^1, C D E♭ F G C^1 D^1 E^1♭ C^1 D^1 B C^1. It is also the scale used in the first two lines of the air from Oberon, already noticed.

We now come to the extension of the diatonic scale by the interpolation of notes between all such notes as are far enough apart to bear it, which completes what is called the chromatic scale. There are various ways in which this can be done, and if notes were only occasionally interposed between those of the diatonic scale, it would be a subject of comparatively little importance how it was done. But we must now explain what is meant by different *keys* in music.

The note C having been fixed, and the diatonic scale on it, let an air be composed and written down, say 'Robin Adair.' The consecutive notes of the first part of this air, played in the key of C, that is, in the diatonic scale which has C for its fundamental note, are (we have nothing here to do with the time)

G A B C^1 D^1 E^1, G C^1 A C^1 B D^1 C

Let us now transpose this, as it is said, into the key of F, that is, show how it is to be played in a diatonic scale having the F of the preceding scale for its fundamental (or key) note. If all the intervals of the scale were equal, this would be done by playing as follows :—

C D E F G A, C F D F, E G F

Again, to remove this air into the key of A, or into the diatonic scale constructed on A, we should write (if the intervals were all equal),

E F G A B C^1, E A F A G B A

If we chose to confound the intervals of a major and minor tone, we should find the second of these (so it happens) correct, for the intervals of the original air are (m, minor tone; M, major tone; s, semitone) m M s M m (2 M + 2 m + s) (M + m + s) (M + s) (M + s) s (M + s) M, and those of the second are M m s M m (2 M + 2 m + s) (M + m + s) (m + s) (m + s) s (M + s) M, which are undistinguishable from each other, if M and m be supposed (as is the fact) too nearly equal to make it worth while to take account of their difference. But the third is s M m M s (2 M + 2 s + m) (M + m + s) (M + m) (M + m) m (m + M) M, which does not agree with either of the other two, nor can do so, except to an ear which cannot distinguish s from m or M. To see what intermediate notes will be wanted, we must construct a diatonic scale on each of the seven notes, which we shall now do, putting an equivalent to every note above C^1 or below C into the octave between C and C^1, by halving or doubling the fraction which expresses its vibrations. Moreover, we express the notes in the diatonic scale on D by D, D_{ii} D_{iii} D_{iv} D_v D_{vi} D_{vii} and D_{viii}; and so on. Also let ${}_{ii}D$ stand for an octave below D_{vii}, ${}_{iv}C$ stand for the note an octave below C_v, and so on, the rule being that ${}_{m}C$ and C_n are octaves when m and n together make *nine*. All this is well known, if anything of the scale be practically understood. What we have to do, for instance in forming the diatonic scale on F, is to take $\frac{4}{3}$, the representative of F in the diatonic scale of C, and multiply it successively by 1, $\frac{9}{8}$, $\frac{5}{4}$, &c. Our scales then are as follows, putting down under each note gained any note of the original diatonic scale, or any one of the scales previously formed, from which it differs insensibly little, removing each note an octave lower when necessary.

(D)	${}_{ii}D$	D	D_{ii}	D_{iii}	D_{iv}	D_v	D_{vi}	D_{vii}
	$\frac{135}{128}$	$\frac{9}{8}$	$\frac{81}{64}$	$\frac{45}{32}$	$\frac{3}{2}$	$\frac{27}{16}$	$\frac{15}{8}$	$\frac{135}{64}$
		D	E		G	A	B	
(E)	${}_{iii}E$	${}_{ii}E$	E	E_{ii}	E_{iii}	E_{iv}	E_v	E_{vi}
	$\frac{25}{24}$	$\frac{75}{64}$	$\frac{5}{4}$	$\frac{45}{32}$	$\frac{25}{16}$	$\frac{5}{3}$	$\frac{15}{8}$	$\frac{25}{12}$
	${}_{ii}D$		E	D_{iii}		A	B	D^{vii}
(F)	${}_{iv}F$	${}_{iii}F$	${}_{ii}F$	F	F_{ii}	F_{iii}	F_{iv}	F_v
	1	$\frac{10}{9}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{3}{2}$	$\frac{5}{3}$	$\frac{16}{9}$	2
	C	D	E	F	G	A		C^1
(G)	${}_{v}G$	${}_{iv}G$	${}_{iii}G$	${}_{ii}G$	G	G_{ii}	G_{iii}	G_{iv}
	1	$\frac{9}{8}$	$\frac{5}{4}$	$\frac{45}{32}$	$\frac{3}{2}$	$\frac{27}{16}$	$\frac{15}{8}$	2
	C	D	E	D_{iii}	G	A	B	C^1
(A)	${}_{vi}A$	${}_{v}A$	${}_{iv}A$	${}_{iii}A$	${}_{ii}A$	A	A_{ii}	A_{iii}
	$\frac{25}{24}$	$\frac{10}{9}$	$\frac{5}{4}$	$\frac{25}{18}$	$\frac{25}{16}$	$\frac{5}{3}$	$\frac{15}{8}$	$\frac{25}{12}$
	${}_{iii}E$	D	E	D_{iii}	E_{iii}	A	B	E_{vi}
(B)	${}_{vii}B$	${}_{vi}B$	${}_{v}B$	${}_{iv}B$	${}_{iii}B$	${}_{ii}B$	B	B_{ii}
	$\frac{135}{128}$	$\frac{75}{64}$	$\frac{5}{4}$	$\frac{45}{32}$	$\frac{25}{16}$	$\frac{225}{128}$	$\frac{15}{8}$	$\frac{135}{64}$
	${}_{ii}D$	${}_{ii}E$	E	D_{iii}	E_{iii}	F_{iv}	B	D_{vii}

In order therefore to make an instrument which shall play in perfect tune in every one of these diatonic scales, we must have it capable of sounding the following notes, those of the original diatonic scale, or very near to them, being in parentheses, and requisite notes of nearly equal sound being written under one another.

$$(1)\quad \begin{matrix}\frac{25}{24}\\ \frac{135}{128}\end{matrix}\quad \begin{pmatrix}\frac{9}{8}\\ \frac{10}{9}\end{pmatrix}\quad \frac{75}{64}\quad \begin{pmatrix}\frac{5}{4}\\ \frac{81}{64}\end{pmatrix}\quad \left(\frac{4}{3}\right)\quad \begin{matrix}\frac{45}{32}\\ \frac{25}{18}\end{matrix}\quad \left(\frac{3}{2}\right)\quad \frac{25}{16}\quad \begin{pmatrix}\frac{5}{3}\\ \frac{27}{16}\end{pmatrix}\quad \begin{matrix}\frac{225}{128}\\ \frac{16}{9}\end{matrix}\quad \left(\frac{15}{8}\right)\quad (2)$$

With this we might go on *ad infinitum*; for it might be required to construct new diatonic scales upon every one of these new notes, which would introduce more new notes, on which again new diatonic scales might be produced, and so on. But since the original scale consists only of major and minor tones (nearly equal) and diatonic semitones (nearly half-tones), the new notes will very nearly divide the whole tones into equal parts, a circumstance of which advantage will presently be taken. In the mean time we proceed to explain, so far as it can be done, the distinction musicians draw between *flats* and *sharps*. Unfortunately we are unable to make writers on this subject agree with each other, or with themselves, as to the meaning of these words in an *untempered* scale. The conventions under which the names sharp and flat are used come easily enough, and temperament avowedly makes small adjustments and accommodations between the several notes, which cause the sharpened A to be practically the same as the flattened B, and so on. But what the clear and admitted distinction of sharp and flat is previously to that adjustment, we wish we could evoke or provoke some musician to tell us. One word to those who write on the scale without much mathematical knowledge: get into a tempered scale as fast as you can, and keep there.

The nomenclature is regulated as follows. The notes A, B, C, D, E, F, G are preserved in every key; so that if any key contain A and a note between A and B, the latter is not called A♯—for then (A A♯) A would occur twice in the scale—but B♭, giving A B♭. Follow this rule in every one of the scales just given, and we shall find the following sets of notes in them severally:—

								Name of the Key.
C	D	E	F	G	A	B	C¹	(natural, . C)
D	E	F♯	G	A	B	C♯	D¹	(two sharps, . D)
E	F♯	G♯	A	B	C♯	D♯	E¹	(four sharps, . E)
F	G	A	B♭	C	D	E	F¹	(one flat, . F)
G	A	B	C	D	E	F♯	G¹	(one sharp, . G)
A	B	C♯	D	E	F♯	G♯	A¹	(three sharps, A)
B	C♯	D♯	E	F♯	G♯	A♯	B¹	(five sharps . B)

That is to say, a diatonic scale on D, for instance, only keeps D, E, G, A, B, or notes very near to them, of the diatonic scale, and requires the insertion of notes between F and G and C and D, which the avoidance of repetition of letters requires us to denote by F♯ and C♯, and not by G♭ or D♭. In the preceding keys then, we have five sharps mentioned (though really seven notes of the kind, two between C and D, two between F and G, one between each of D and E, G and A, A and B) and one flat (between A and B). Where are the other two sharps? If we construct diatonic scales upon F♯ and C♯ we shall find

F♯	G♯	A♯	B	C	D♯	E♯	F¹♯	(six sharps, . F♯)
C♯	D♯	E♯	F♯	G♯	A♯	B♯	C¹♯	(seven sharps, . C♯)

with not precisely the same notes as before, but very near to them, excepting two notes which are new: one between E and G (called E♯), and one note between B and C (called B♯). But on which of the values of F♯ and C♯ in the table are these scales to be constructed, and why? Again, as to the flats, if we construct diatonic scales on B♭, and on each new flat as it is successively introduced, we shall find that our nomenclature gives us new keys, as follows:—

B₁♭	C	D	E♭	F	G	A	B♭	(two flats, . B♭)
E♭	F	G	A♭	B♭	C¹	D¹	E¹♭	(three flats, . E♭)
A₁♭	B₁♭	C	D♭	E♭	F	G	A♭	(four flats, . A♭)
D♭	E♭	F	G♭	A♭	B♭	C¹	D¹♭	(five flats, . D♭)
G♭	A♭	B♭	C′♭	D¹♭	E¹♭	F¹	G¹♭	(six flats, . G♭)
C♭	D♭	E♭	F♭	G♭	A♭	B♭	C¹♭	(seven flats, . C♭)

But if we were actually to proceed to form this scale, beginning from B♭ ($\frac{16}{9}$) gained from the preceding process, we should find ourselves keeping very near the chromatic scale of sharps already obtained, so that the notes which appear in the preceding as remnants of the diatonic scale would really be close to the real notes. Let us see, for intance, what the F would be in the key of G♭:—

B♭, a fourth above F $=\frac{16}{9}$, E¹♭, a fourth above B♭ $=\frac{64}{27}$.
E♭ $=\frac{32}{27}$, A♭, a fourth above E♭ $=\frac{128}{81}$.
D¹♭, a fourth above A♭ $=\frac{512}{243}$, D♭ $=\frac{256}{243}$.
G♭, a fourth above D♭ $=\frac{1024}{729}$.
F¹ (so called), a seventh above G♭ $=\frac{1024}{729}\times\frac{15}{8}=\frac{640}{243}$.
F (so called) $=\frac{320}{243}$. F (really) $=\frac{4}{3}$.

Now from $\frac{320}{243}$ to $\frac{4}{3}$ the interval is only $\frac{81}{80}$, the comma, which we meet with so often elsewhere. But we should find different values for the same flat in the different keys above, just as we have found different values for the same sharp in the preceding. To show, however, in how confused a state the natural chromatic scale has been left, we copy three scales, the first from Wallis ('Phil. Trans.,' No. 242, 1698), the second from La Borde ('Essai sur la Musique ancienne et moderne,' vol. ii. p. 9, A.D. 1780), and the third from Montferrier ('Dict. des Math.,' vol. iii. p. 243, A.D. 1840). All these writers *omit the flats*, mentioning only the sharps:—

C	C♯	D	D♯	E	F	F♯	G	G♯	A	A♯	B
1	$\frac{18}{17}$	$\frac{9}{8}$	$\frac{45}{38}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{24}{17}$	$\frac{3}{2}$	$\frac{30}{19}$	$\frac{5}{3}$	$\frac{30}{17}$	$\frac{15}{8}$
1	$\frac{25}{24}$	$\frac{9}{8}$	$\frac{75}{64}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{45}{32}$	$\frac{3}{2}$	$\frac{25}{16}$	$\frac{5}{3}$	$\frac{225}{128}$	$\frac{15}{8}$
1	$\frac{16}{15}$	$\frac{9}{8}$	$\frac{6}{5}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{45}{32}$	$\frac{3}{2}$	$\frac{8}{5}$	$\frac{5}{3}$	$\frac{16}{9}$	$\frac{15}{8}$

It has been laid down by some writers that the definition of a sharp and flat is as follows: when it is necessary to take a note between, say A and B, that note is called A♯ when it is nearer to A, and B♭ when it is nearer to B. Let such be the definition; then the note which is exactly half way between C and D, being expressed by $\sqrt{(9:8)}$, is 1·0607, while $\frac{18}{17}$, $\frac{25}{24}$, and $\frac{16}{15}$ are severally 1·0588, 1·0417, and 1·0667. The two first only come under the denomination of C♯, according to this definition, while the third ought to be called D♭. In fact, this third scale is almost a scale with its semitones, collected from the minor keys which are found to please the ear, with a slight alteration and one addition. In (2) B♭ is made as a fourth to F, instead of a fifth to E♭ (giving $\frac{16}{9}$ in place of $\frac{9}{5}$, the interval of the two being only a comma); let $\frac{9}{5}$ be taken instead of $\frac{16}{9}$. Then between F and G insert G♭, a minor third to E♭ (giving $\frac{36}{25}$). Take the simplest sharps from the diatonic scales hereinbefore found, and, putting all the results together, we shall have the following, which, if a complete untempered ENHARMONIC scale is to be given, will, we believe, be as defensible as any. The sharps are all derived from the diatonic major scale, the flats from minor scales made by the usual minor intervals; the sharp of each note is lower than the flat of the following, though the former and the latter are not always in different halves of the interval:—

C	C♯	D♭	D	D♯	E♭	E	F	F♯	G♭	G	G♯	A♭	A	A♯	B♭	B	C
1	$\frac{25}{24}$	$\frac{16}{15}$	$\frac{9}{8}$	$\frac{75}{64}$	$\frac{6}{5}$	$\frac{5}{4}$	$\frac{4}{3}$	$\frac{45}{32}$	$\frac{36}{25}$	$\frac{3}{2}$	$\frac{25}{16}$	$\frac{8}{5}$	$\frac{5}{3}$	$\frac{225}{128}$	$\frac{9}{5}$	$\frac{15}{8}$	2

The enharmonic intervals of this scale are as follows:—

C♯ D♭ = 1·024, D♯ E♭ = 1·024, F♯ G♭ = 1·024, G♯ A♭ = 1·024, A♯ B♭ = 1·024:

so that this enharmonic interval will be in every instance $\frac{128}{125}$, or 1·024. This circumstance was not looked for in the formation of the scale, and it is thus seen that if the sharps be derived from the major diatonic scales of the different notes in the fundamental diatonic scale, and the flats solely from the minor scales which have been judged admissible, the result is an enharmonic scale in which the enharmonic interval is everywhere the same, namely, the interval by which three major thirds fall short of an octave.

If an instrument could give all the above sounds, the same music played in different keys would have slightly different effects. We remember to have seen a statement of the supposed characters of the different keys, which would be useless here, on account of its not describing the scale which was supposed to be the basis. We might suppose beforehand that of two keys, the one in which some prominent consonances are a little flatter than in the other, would partake, in a slight degree more than the other, of the plaintive character which distinguishes the minor keys. But, in the first place, instruments in general, and particularly the piano-forte, on which the greater part of music first comes into existence, have not two notes interposed between each note of the diatonic scale, but one only, which must serve both to sharpen the lower, and flatten the higher. Next, the preceding scale would be found not very tolerable in some keys, particularly if laid down on an organ. Some TEMPERAMENT, that is, mutual accommodation of notes to each other, would be necessary, and though we defer to a separate article the account of the systems which prevail, or have been proposed, it will be desirable here to lay the mathematical foundation of the subject, which is easy enough to one who can use logarithms. The following table will be necessary, which we proceed to explain :—

1	00·00	51	68·07	101	79·90	151	86·86	201	91·81
2	12·00	52	68·40	102	80·07	152	86·98	202	91·90
3	19·02	53	68·73	103	80·24	153	87·09	203	91·99

49	67·38	99	79·55	149	86·63	199	91·64	249	95·52
50	67·73	100	79·73	150	86·74	200	91·73	250	95·59

Since all intervals are found by *multiplication* and *division*, it is obvious that if for intervals we substitute the logarithms of intervals, we form logarithms of new intervals by *addition* and *subtraction*. Hitherto, we express a note which makes a vibrations while the fundamental note makes b vibrations, by $\frac{a}{b}$; let us now express it by log a − log b, the logarithm of the preceding. It only remains to see what system of logarithms it will be most convenient to take. Having made the octave, or the interval from 1 to 2, consist of twelve semitones (not equal indeed, but nearly so), let us take a new scale, to which all others shall be referred, and which divides the octave into 12 *equal* semitones. This is a tempered scale, on the (theoretically) simplest system of temperament, and it is agreeable enough to the ear in practice. Let 1 be made the logarithm of the interval of any one of these mean semitones, then 12 is the logarithm of the interval of an octave, or we must choose that system of logarithms in which log 2 = 12. The preceding is such a table; to the mathematician it would be described as a system the base of which is $\sqrt[12]{2}$. But to the musician it may be described as follows: it shows the number of mean semitones contained in every HARMONIC of the fundamental note, from the first to the 250th inclusive. Thus, opposite to 21 we see written 52·71, which means that the 21st part of a string sounds a note which is 52 mean semitones and ·71 or $\frac{71}{100}$ of a mean semitone above the fundamental note of the string; or that there are 52·71 mean semitones of interval between two notes, one of which vibrates in a second 21 times as often as the other. This interval ·71 of a mean semitone is one which, repeated a hundred times, gives 71 mean semitones. All the numbers of the table must be understood to be approximate, within the hundredth of a semitone or thereabouts; which is more than exact enough for practical purposes. The following rule is all that is necessary :—If a note make $\frac{a}{b}$ vibrations while the fundamental note makes 1, then that note is log a − log b mean semitones above, or log b − log a mean semitones below, the fundamental note, according as a is greater than b, or b greater than a.

Example 1. What is the value of a comma in mean semitones? Log 81 − log 80 is 76·08 − 75·86 = ·22, and the answer is, that the comma is 22-hundredths, or something less than a quarter, of a mean semitone. Raising a note by a comma four times successively would not raise it quite a semitone.

Example 2. What is the enharmonic interval above obtained, in mean semitones? Log 128 − log 125 = 84·00 − 83·59 = ·41, or about four-tenths of a mean semitone. This shows that an untempered enharmonic scale, such as that proposed, if bearable when the sharps and flats are only incidental deviations, would never do for any other key except the natural one.

The following is the complete basis above given, of the enharmonic scale, with all the intervals, measured from the fundamental note, expressed in mean semitones; it shows how much alteration a system of mean temperament would require: it being remembered that although some few instruments have been made which give more than twelve different notes in the octave, this is so unusual a circumstance that it is not worth while to dwell upon it :—

							·41
C	1	00·00	·71	G♭	$\frac{64}{45}$	6·31	·71
C♯	$\frac{25}{24}$	00·71	·41	G	$\frac{3}{2}$	7·02	·71
D♭	$\frac{16}{15}$	1·12	·92	G♯	$\frac{25}{16}$	7·73	·41
D	$\frac{9}{8}$	2·04	·70	A♭	$\frac{8}{5}$	8·14	·70
D♯	$\frac{75}{64}$	2·74	·42	A	$\frac{5}{3}$	8·84	·92
E♭	$\frac{6}{5}$	3·16	·70	A♯	$\frac{225}{128}$	9·76	·42
E	$\frac{5}{4}$	3·86	1·12	B♭	$\frac{9}{5}$	10·18	·70
F	$\frac{4}{3}$	4·98	·92	B	$\frac{15}{8}$	10·88	1·12
F♯	$\frac{45}{32}$	5·90		C	2	12·00	

The first column gives the name of the note; the second, the ratio of its number of vibrations per second to those of the fundamental note; the third, the interval from the fundamental note in mean semitones; the fourth, the interval between each consecutive pair of notes. The small variations observable in the last column arise from imperfection of the table (every table must be imperfect in its last figures); and we see four intervals in it, namely, the old diatonic semitone 1·12, the *major* and *minor chromatic semitones* (as we will call them) ·92 and ·71, and the enharmonic interval (or enharmonic *diesis*, as it is called) ·41. And the major tone is in every instance

maj. chrom. semit. + min. do. + enh. int.

while the minor tone is

2 min. semit. + enh. int.

If we confound the major and minor tone (and to distinguish them is the *ultima Thule* of temperament), we must take a mean value, and substitute it both for the major and minor chromatic semitone. The mean tone is 1·9, which is to the diatonic semitone nearly as 5 to 3. The mean chromatic semitone is ·81, about $\frac{2}{3}$ of the diatonic semitone, and the enharmonic interval is its half. This is a well-known system of temperament (that of Huyghens): the octave being divided into 31 equal parts, five of them are a tone, three a diatonic semitone, two a chromatic semitone, and one the enharmonic interval. Introduce E♯ and C♭, which are omitted in the preceding, and we have the following for a tempered enharmonic scale, upon which we doubt of any improvement being practicable, without attempting the distinction between a major and minor tone :

C C♯ D♭ D D♯ E♭ E F♭ E♯ F F♯ G♭ G G♯ A♭ A A♯ B♭ B C♭ B♯ C
2 1 2 2 1 2 1 1 1 2 1 2 2 1 2 2 1 2 1 1 1

This system, however, is useless, inasmuch as instruments are required to have only twelve notes in the octave; but we should recommend the student to bear it in mind, as explaining those enharmonic changes which in piano-forte music are only fictions. This scale would enable us to play with equal correctness in all keys up to seven flats among the flats, and seven sharps among the sharps. Naming these keys by their principal notes, they are the keys of

C G D A E B F♯ C♯
F B♭ E♭ A♭ D♭ G♭ C♭

Now suppose an incidental deviation into the key of A♯. Looking into the preceding scale from A♯ ascending, we find we can get a whole tone at B♯, but the next whole tone is wanting, nor can we get it except by interposing a note between D♭ and D, two tempered chromatic semitones above C, and therefore called C♯♯ or C×. On the piano-forte we must be content with D for C♯♯, and accordingly we have in like manner

E for D♯♯, D for E♭♭, D♯ for F♭♭, &c.

In the preceding scale also, when enharmonic transitions are written, they can most frequently be actually made; on the piano-forte, though written, they can only be made in imagination. The ear, knowing what is coming, so soon as the enharmonic modulation is *seen*, prepares itself for a change of key, and gives the chord in its possession to the mind not altogether in the same way as when it was not a note of preparation. If any one will compare the effect of music heard the second time with that produced by the first time, he will, we think, be inclined to accede to our opinion, that sounds heard without any knowledge of what is to come afterwards, differ more from those which are heard with such knowledge than the effects of two scales constructed on the two most remote of all the approved systems of temperament. In Huyghens's system, his subdivision is ·387 of a mean semitone, the chromatic semitone is ·774, the diatonic semitone 1·161, and the tone 1·935.

The harmonics of any string C may be readily found from the table, reduced into the octave between C and C^1; they may then be compared with the untempered diatonic scale. For example, what is the 53rd harmonic of C? C itself counting as the first. It is by the table 68·73 mean semitones above C, lower this five octaves, by subtracting 60, and we have 8·73, lying therefore between A ♭ and A, but nearer to the latter.

[Chromatic Scale; Diatonic; Enharmonic. For Scales of Voices, Alto, Base, &c. For Scales of Musical Instruments, Bassoon, Clarinet, Harp, Violin, &c.]

SCALENE, a name given by Euclid, in his definitions (but seldom or never afterwards used by him), to a triangle no two sides of which are equal to one another.

SCAMMONY, properly so called, is, in the present day, the produce of *Convolvulus scammonia*, a plant growing in Greece and the countries along the Levant. The scammony of the ancients was in all probability yielded by *C. sagittifolius* (Sibthorp), *C. Sibthorpii* (Romeretsch), from which it is conjectured that the scammony called of Samos or Trebizond is obtained. The best comes from Aleppo; the next from Smyrna. The French scammony, called Montpellier S., is the produce of *Cynandum Monspeliacum*, an asclepiadaceous plant, endowed with most of the acrid and poisonous properties of that tribe, and therefore a dangerous substance. But even of the products of convolvulaceous plants the qualities are so various, either from natural inferiority, or, far more frequently, from carelessness in collecting it, or intentional adulteration, that no drug is more unequal in its constitution or more uncertain in its operation. Strictly speaking, it is a gum-resin; but the proportion of gum is at all times small, while the resin in different specimens varies from 81 per cent. in the best to 16 in the worst. Besides mechanical impurities, such as sand, fragments of the stem or roots, owing to the manner of collecting. chalk, and flour of wheat or barley, or dextrine, are purposely mixed with it to bring it down to the market price. The latter sophistications are not objectionable, further than they necessitate a larger and more bulky dose. But a most pure preparation can now be obtained by extracting the resin from the root itself, according to the patent plan of Prof. Williamson, suggested by Mr. Clark of Sockia, Asia Minor. (See 'Pharm. Journ.,' vol. xvii., p. 37; and vol. xviii., pp. 449 and 546.) For an account of the mode of collecting scammony in the north-west of Asia Minor, see the same Journal, vol. i., p. 522, new series, April, 1860. Perfectly pure scammony is, in a very small dose, a very efficacious purgative, clearing away mucous accumulations, more especially from the bowels of children, which are the favourite resort of worms. To expel these, scammony is often associated with calomel; but this is generally needless, as extract of rhubarb, from its bitter and tonic properties, is in every way more to be commended. By giving bitartrate or tartrate of potass, with carbonate of soda, its properties are heightened, and it may be rendered a useful hydrogogue cathartic. It should not be too frequently repeated, as it is apt to abrade the mucous covering of the intestines; nor should it be given in inflammation of these.

SCANDAL (*scandalum magnatum*, slander of great men). By the statute 2 R. II., c. 5, confirmed 12 R. II., c. 11, as to "devisers of false news and tellers of horrible and false lies of prelates, &c.," it was enacted that none devise or speak false news, lies, or other such false things of the prelates, nobles, and great men of the realm. By the same statute the tellers of such lies were liable, as by the statute of Westminster the first, to be imprisoned till they discovered the authors of them. No statutory punishment was provided against the authors, perhaps because they were liable at common law to fine and imprisonment. Upon this statute is founded the action of scandalum magnatum, which is now fallen into disuse, and superseded by the common action of libel and by the criminal information. It lies at the suit of any nobleman, though of a dignity created since the date of the statute, of the judges, and of other great officers of the realm. It has been held that the action may be brought not only for such words as are actionable in ordinary cases, but even for those which are not certain enough to maintain an action against a common person, as where one said, "My lord has no more conscience than a dog."

The object of the statute originally, though afterwards it appears to have been applied in private cases, was wholly of a political character. The mischief recited is that "debates and discords might arise betwixt the said lords, or between the lords and the commons, which God forbid, whereof great peril and mischief might come to all the realm, and quick subversion and destruction of the aforesaid realm." The statute of Westminster, 3 Edw., c. 33, referred to, is also directed to cure the same mischiefs, the discord and scandal that might arise between the king and his people, or the great men of the realm.

The term *scandalous* is applied to matter in a bill or answer in chancery which reflects on the character of a defendant or plaintiff, and is at the same time irrelevant. Such matter will be struck out on exceptions being taken to it and allowed.

(2 *Inst.*, 225; Com., *Dig.*, tit. 'Action on the case for Defamation;' B., *Libel*, C. 5.)

SCANDINAVIAN LITERATURE. The ancient Scandinavian language, once common to the whole north-western portion of Europe beyond the Baltic, is now confined to Iceland, where it has undergone little change since the 9th century. [Iceland, in Geog. Div.] This dialect of the Gothic is the parent stock of both Swedish and Danish, the former of which tongues has retained more of the original character than the other, which is also the language of Norway; and, if not for the literature they contain, in a philological point of view they deserve far more attention than they have hitherto obtained from Englishmen, since they throw considerable light on the history of our own language. There is also a striking similarity of construction between them and English, which renders them of comparatively easy acquisition to ourselves. Nearly the same grammatical simplicity prevails, nor are their verbs and nouns subject to those numerous changes of terminations which render such languages as the German and the Russian so perplexing to a foreigner.

Though literature, in the usual meaning of the term, was of exceedingly tardy development in both Denmark and Sweden, the people possessed an abundant stock of those traditional poetical records which scarcely lay any claim to individual authorship, being rather the embodying of the sentiments and feelings of an entire race than those of individuals. Of these, by far the most important are the Eddas. Though committed to writing by Bishop Sämund only in the 11th century, it is supposed that an earlier collection was then in existence. A part of Bishop Sämund's gathering has been lost, and what remains we owe to Snorri Sturluson, the grandson and pupil of Sämund. The elder Edda is in verse, not rhymed, but rendered metrical by the use of alliteration or assonance, in which the alliteration is employed twice in the first line of a couplet, and the second begins with the same letter. Many variations, including end rhymes, were subsequently introduced. The younger Edda is in prose, with a mixture of verse, partly quoted from earlier poems, in nearly every case from the elder Edda.

Though a distinction has been drawn between the elder and younger Eddas, there is little doubt but that some parts of the latter are at least equal in antiquity to some of those in the elder: and as little that in the elder Edda there have been many interpolations, which have been pointed out by Simrock ('Die Edda, die ältere und jüngere,' 1855), who, however, says, "Who would venture to lay hands on so reverend a piece of antiquity, and where would it end if each were to follow his inclination or caprice, and began to model the tradition according to his own notions." The elder Edda consists of thirty-seven poems, of various degrees of poetical merit, all relating to the mythology, which will be treated of in the next article. After being forgotten for nearly four centuries, a copy was found by Bishop Svensen, and published in 3 vols. 4to, containing the original text, a Latin translation, and a dictionary of the northern mythology, in 1787. A later and more correct edition has been since published by Rask in 1818.

The later Edda is divided into two books,—Gylfaginning, or Gylfa's fascination, and relates a like story to that of Vafthrudnismal (or song of Vafthrudni) in the elder Edda; but occasion is taken to deliver the principal doctrines of the northern faith in answer to the disguised Odin's inquiries. Bragaroedhur, or Bragi's Discourse, borrowed also from the Oegirsdrecka, or Oegir's Drinking Feast: here Bragi, the scald of the gods, discourses of the origin of poetry. These were first translated and published by Resenius in 1640. In some manuscripts, however, and in Rask's printed edition, these are accompanied by some of the Scaldaic songs. [Scald.]

Of other Scandinavian poems there are many distinguished by the title of Kämpe Viser, or Heroic Ballads, which strains of romantic minstrelsy serve to give an idea of the compositions of the ancient bards or scalds. Deeds of arms and bravery constitute their main subjects; for in the infancy of states personal courage and physical strength are regarded as the chief titles to pre-eminence, more especially in such a region as Scandinavia, where the sword was the only patrimony of the younger branches of a family, and was a possession quite as honourable and frequently more lucrative than that of the soil. Possessing a very great extent of sea-coast, the inhabitants regarded that element also as their natural territory. Their piratical expeditions, undertaken partly through necessity and partly from the love of adventure, obtained for them a fearful fame; and the leaders of these hardy pirates assumed the imposing title of Sea-kings. These 'Viser' contain moreover no small quantity of legendary fable and supernatural lore, derived from the ancient Sagas and the mythology of the Edda [Scandinavian Mythology], whose wild traditions were so congenial to the spirit of the people that they continued to cherish the remembrance of them long after the establishment of Christianity (which was not earlier than the commencement of the 11th century); and in modern times they have been largely made use of by Oehlenschläger and other living or recent poets, who have found in them a source of powerful interest for their countrymen. For a while indeed it was very doubtful whether the Gospel would prevail against the popular belief in the Valhalla. The labours of the early missionaries in the 9th and 10th centuries produced very little effect; the people continued to be almost entirely pagan, and Svend Tvæskæg, the successor of Harald, renounced Christianity, and did all he could to re-establish the worship of the ancient idols; nor was it until after the accession of Canute the Great (1014), that Christianity became the national religion, and churches and convents began to be built. For several years afterwards, however, little improvement took place in the intellectual condition of the people. Literature can hardly be said to have been cultivated at all. Its sole monument is the history (written in Latin) by Saxo Grammaticus, who died in 1208. In Germany, as well as in England and Scotland, where this literature and mythology were once predominant, both faded away more quickly under the influence of civilisation. Odin, or, as he was called by those nations, Woden, was forgotten, but the popular tales and fictions remained. The ballad poetry of Scotland retains many a lay identical almost with those of the Scalds; while Puss in Boots, Blue Beard, the Pig who would not go over the style, and Jack the Giant-killer, have their Scandinavian originals. Howitt's 'Literature and Romance of Northern Europe;' and Dasent's 'Tales from the Norse,' contain much that is interesting on the subject.

Of the modern literature of the Scandinavian nations, Iceland, Sweden, Norway, and Denmark, notices will be found in the BIOGRAPHICAL DIVISION, under the names of the more eminent authors.

SCANDINAVIAN MYTHOLOGY. The genuine and older Scandinavian mythology, which, in regard to wild imagination, sublime conceptions, a rough vigour, and a naïve simplicity sometimes approaching the ludicrous, will bear comparison with those of the Hindus, the Greeks, or Romans; and which, from the extensive influence it has exercised on all nations of Gothic and Teutonic descent, has a peculiar interest for them, is to be found in the Edda, a word meaning great grandmother, or rather ancestress, probably used to indicate that the cycle of poems, to which the name is given, had a more remote origin. As we have stated in the preceding article [SCANDINAVIAN LITERATURE], the Edda consists of two parts—the elder Edda, a cycle of poems, and the younger or prose Edda, which is chiefly a compendium of the elder, with occasional extracts from it.

The Scandinavian mythology comes to us, not in the shape of a religious system, so much as the poetical expression of some of the worshippers. It does not approach a system even so much as Hesiod's Theogony; for it has to be gathered from various poems or fragments of poems, of which some are manifestly of much greater antiquity than others. Some, no doubt, are of a period anterior to the Christian era; but as all were collected at a long subsequent period, it is probable that the belief in the destruction of the world and its renovation may have been derived from Christian sources. Thus the Edda presents in the very beginning the germs of one all-destroying catastrophe, of a creation which by necessity involves the final destruction of the universe, with a promise of a resurrection and a happier existence. This destruction has been long foretold.

The history of the Creation by the Asar has little resemblance to that of Christianity. In every creation by the heathen gods, the material stuff is always in existence. In the Asar creation, the world becomes a living organism. Nature is not a rude mass, she is not dead, but an organised whole, that is ever penetrated by a superhuman life. When this idea, which approaches to the pantheistic, is expressed in a poetically-material manner, we may compare it with other mythologies, in which, like it, giants, Titans, Cyclops, the original dwellers in Chaos, embody the unrestrained force of the elements till subjected to the might of a higher and regulating power. There is also the peculiarity of accepting the principle of evil as the first existence, to counteract which the principle of good was formed, or rather descended, for Odin's mother was a daughter of the giants.

In the beginning was a chaos. On the north was Niflheim, cold, dark, and foggy; on the south, Muspelheim, warm and light; betwixt these two was Ginnunga-gap, in which contended the ice and frost of Niflheim, the light and heat of Muspelheim, and into which flowed twelve streams called Elivagar, which were poisonous, issuing from the fountain Hvergelmir. This water, hardened by the frost, by degrees filled the gap; was again gradually melted by the warmer south; and the heat thus imparted at length produced Ymir, a being of enormous size and malignant disposition. Ymir fell asleep, and under his left arm grew a male and female; from his right hand and foot a six-headed giant. These were the progenitors of the race of giants. The ice continued to melt, and a cow, Audhumbla, was produced, by whom Ymir was nourished from its four milk-streams (the four elements). The cow, Audhumbla, licked the icy salt-stones, and on the evening of the first day arose the hair of a man, on the second his head, and on the third the complete man, handsome, large, and strong. He was named Buri, and had a son (no mother is mentioned) called Bör, who took to wife a daughter of the giant Bölthorn, and had by her Odin (or Odhin, the Woden of the Saxons), Veli, and Ve—the first of the Asar. These three having slain Ymir, carried the body to Ginnunga-gap, and with it therein formed the world: the blood became water; the flesh, earth; the bones, mountains; the teeth, pebbles; the hair, grass, trees, and other vegetation; the skull, the firmament; the brains, thrown into the air, became clouds; and of the eyebrows were made a wall of defence against the frost-giants. This round flat world was called Midgard, and was encircled by a deep ocean (sometimes typified by a vast serpent), outside of which was Jötunheim, the abode of the giants. With sparks of hot cinders from Muspelheim were formed sun, moon, stars, lightning, and meteors; and their courses were prescribed, thus forming night and day, and the seasons.

Asgard, the residence of the Asar, was apportioned into Vanheim, the domain of the elementary deities; Glad-heim, in which was Valhalla, where dwelt Odin and the deities of his family; Muspelheim, the district of celestial fire; and Licht-Alfheim (elves of light), the residence of the benevolent dwarfs, or elfs, in which also was situated Gimli, the place of future beatitude.

Utgard was under the earth, deprived of the sun's light, and was divided into Jötunheim, the country of the giants; Swart-Alfheim, that of the black dwarfs, or gnomes; Niflheim, in which was Hel, the residence of Hela, goddess of death; and Naströnd, a horrible swamp, inhabited by serpents, into which, at the end of the world, the wicked are to be thrown.

According to the Völuspá, the (three?) gods in council next created the dwarfs, who had been bred like maggots from the corruption of Ymir's blood, and who were now endowed with human shape, though often deformed; and they formed a counterpoise to the giants, who are represented as stupid, while the dwarfs make up for their want of size by their ingenuity, acuteness, and knowledge. They have still, however, to dwell in the earth or in rocks and caverns. The Völuspá and the prose Edda differ here, as the Völuspá says they were created from Brimir's blood. They also differ as to the next creation, that of mankind. The Völuspá says, after creating the dwarfs,—

> "Then the three went, From this assembly,
> Mighty and mild The Asar especially.
> They found on the sea-coast, Powerless,
> Ask and Embla, Without fixed destiny;
>
> Possessing no soul, Having no sense,
> Neither blood nor motion, Nor yet blooming colour.
> Odhin gave soul, Hönir gave sense,
> Lodur (Loki) gave blood and blooming colour."

In the prose Edda, as the children of Bör wandered by the sea-shore they found two trees, of which they formed the male and female, Ask and Embla: Odin bestowing on them life and spirit; Veli, sense and feeling; and Ve, visage, speech, hearing, and sight; and from these two are descended the whole human race. Jacob Grimm remarks on this ('Deutsche Mythologie') that only dwarfs and men are created; the giants and the gods come into existence as if of themselves, from the influence of merely natural forces; they owe their being to the union of fire and water, while mankind and the men-like dwarfs are made by the formative activity of the gods themselves acting with a purpose.

After the creation came the golden age of the Asar, till at length three maidens of the race of giants surprised them. They took away their golden table, and left instead a desire for gold; this led to a war with the Vanir, who had broken down the outer wall of Asgard; but a peace was at length concluded, when Hödur was given as a hostage on one side, and Niörd on the other, who received a seat and a dwelling in Asgard.

Ygdrassil, the tree of life, which forms so important a part of the cosmogony, is first mentioned very abruptly in the 'Völuspá,' and equally so in the 'Grimnismal' (song of Grimni). This tree has three roots, one in heaven, one in the residence of the Frost-giants, and the third in Niflheim or Hela. At each root was a fountain possessing wonderful powers, and its branches spread around the whole universe. At the root in Niflheim lives the serpent Nithhögg, constantly gnawing them, and in its topmost branches sits an eagle with a hawk between his eyebrows. A squirrel, Ratatoska, runs up and down, exciting strife between the eagle and the serpent; and on its branches browse four stags. The tree is an ash, and is the greatest and holiest of all trees, uniting heaven, earth, and the lower regions. The springs are also sacred. Round the heavenly Urdar-brunnen the Asar assemble every day to pronounce judgments, assisted by the three chief Nornen—Urd, Verdaldi, and Skuld. There are, however, many other Nornen, who decide on the length of life, and the good or ill-fortune of every individual of the human race, some of whom are descendants of the Asar, some, of the races of elves, and some of the race of the dwarfs. Every day the Nornen water the tree from the fountain, to keep it in vigour, and from its leaves falls the dew. The well of the giants is guarded by Mimir, an old and wise man, but whether god, giant, or demi-god is uncertain, and in this well lie hidden wisdom and knowledge. The third is Hvergelmir or the roaring basin.

The chief gods, who were especially to be worshipped, are twelve; the goddesses are fourteen. The subordinate superhuman powers are numberless. We only enumerate the chief, which are—1, Odin, who governs all things, and who is obeyed by the other deities, as a father by his children. Hence he is named Alfadir (All-father) and, with numerous other names, Valfadir, from having prepared Valhalla and Vingolf for the reception of the Einheriar (his selected heroes) who have fallen in battle. Near his seat in Hlithskialf are two wolves, which he feeds with the viands set before him, as he needs no food; and on his shoulders sit two ravens, Hugin and Munin (Thought and Mind) who whisper in his ear all the tidings they have collected. His wife is Frigga, who foresees all things, but never foretells them. 2, Thor, the mightiest and strongest of gods or men; possessing a hammer, Miölnir, of enormous power, which returns of itself to him after having been flung at any one; a belt by which his strength is doubled when it is worn; and gauntlets without which he cannot grasp the handle of his hammer. He was the son of Odin by Fiörgyn (the earth), who also figures as a male, the father of Frigga, the wife of Odin. Thor is the protector of the earth, whose cultivation he has established, whose fruitfulness and kindliness in favour of its inhabitants he unweariedly fosters and furthers, and is therefore in continual conflict with the wild elements. His wife is Sif, from whom by a trick Loki stole her hair, and was forced by Thor to supply its place with hair of gold. 3, Baldur, the second son of Odin by Frigga, the handsomest and best of the Asar, the wisest, mildest, and most eloquent. His wife was Nanna. He was early threatened with death, to guard against which every created thing was required to swear to do him no harm; but, instigated by Loki, his blind half-brother, Hödur (unreasoning strength), slew him by throwing at him a branch of mistletoe, which had been overlooked in the swearing. His fate occasioned the visit of Odin to Hela, which has been paraphrased by Gray. 4, Niörd governs the winds, stills the sea, and checks the fire. But he is not of the race of the Asar. Born and bred in Vanaheim, a district of the giants, he was given as a hostage to the Asar on a peace being concluded with the Vanen, who received from the Asar as a hostage on their part, Hödur, one of the joint creators of mankind. His wife was Skadi, daughter of the giant Thiassi. They had two children; a son named Freyr, and a daughter named Freyja, both beauteous and powerful. 5, Freyr governs the rain and sunshine, gives abundant harvests, promotes peace, and dispenses riches to men. He fell in love with Gerda, the daughter of Gymir, one of the giants in Jötunheim, and obtained her for his wife through the intervention of Skirnir, and this forms the subject of one of the poems of the elder Edda, Skirnirsfôr or Skirnir's Journey. His sister is equally benevolent, she assists all who desire her assistance, is especially favourable to lovers, and claims the half of all who fall in battle (the other half belonging to Odin), whom she entertains in Sessrumnir, her mansion in Asgard. 6, Tyr, whose descent is uncertain, is bold and courageous, promotes strife, and gives victory in war. He has but one hand, as the other was bitten off by Fenrir, the wolf, who demanded of the Asar the pledge of one of their hands in his mouth before he consented to be bound in order to try his strength. None of the Asar dared this but Tyr. The wolf remains bound until the day of the destruction of the world. 7, Bragi, celebrated for wisdom, eloquence, and his skill in poetry: he was the skald of the gods. His wife was Iduna, who had charge of the golden apples, by eating of which the gods renewed their youth. Loki by a trick delivered her and her apples to one of the giants; the gods became wrinkled and gray; and then Loki by another trick brought her and her treasure back to the Asar. 8, Heimdall is one of the Asar, the son of nine virgin sisters, but beyond the epithet *weisse Aes* (white Aes, singular of Asar) his descent must be admitted as obscure. He was a powerful god, and much honoured. He is the warder of the bridge Bifröst (the rainbow), requires less sleep than a bird, sees by night as well as by day, can even hear the grass grow on the earth, and the wool on the sheep's back. His horn when sounded is heard all over the world, and his sword fights of its own accord. 9, Vidar is one of the sons of Odin, and surnamed The Silent. He is next to Thor in strength, and on the day of combat against the giants is to kill the wolf Fenrir, by driving his sword down his open jaws. 10, Vali, another son of Odin's by Rinda, who undertook to revenge the death of Baldur, and assisted in binding Loki. 11, Ullur is the son of Sif, step-son of Thor, skilful with the bow, swift on snow shoes, handsome and brave. 12, Forseti, the son of Baldur and Nanna, celebrated for his correct judgments, from which all disputants depart satisfied. Other lists somewhat vary from this. Hödur, the blind and strong, has been mentioned, but seems not to be included among the twelve. The prose Edda says, "the gods might well wish they had never to name him, for too long will his deed remain in their memory."

Besides the Asar, there are some other important deities. One of the chief is Loki, one of the sons of the giant Farbauti and Nal, or Laufey, his wife; the others being Byleist and Helblindi. Loki is handsome in person, but capricious, cunning, and perfidious. He was at times the friend, and commonly the associate, of the Asar, but the continual contriver of mischief against them. He had a wife called Siguna, and a son by her named Nari, who was devoured by his brother, the wolf. But his most celebrated progeny was by the giantess Angurbodi, by whom he had the wolf Fenrir, who used to follow the sun, endeavouring to swallow it, whose binding has been already mentioned, and who will at length break loose, and assist in the destruction of the world; the serpent Jormungand, who was thrown by the gods into the deep ocean that surrounds Midgard, which he encircled, holding his tail in his mouth; and Hela, who was cast into Niflheim, and has power over nine regions, into which she distributes all who die through old age or sickness. The dominion of Hela is not a place of punishment, but only the abode of those not deemed worthy of dwelling in Valhalla. Loki himself is at length bound on sharp-pointed rocks, with a serpent suspended over him; whose venom should fall on his face, but his wife Siguna catches the drops in a cup till it is full; she then has to empty it; and while this is being done, the drops which fall on his face cause such extreme pains, that he writhes and causes earthquakes. He is thus to lie till the end of the world. Oegir, also called Gymir, is one of the giants, and has dominion over the sea. It will be seen that Odin's two brothers, Veli and Ve, have disappeared. At the end of heaven sits Hrässchwelger (corpse-devourer), one of the giants, in the shape of an eagle, and from the flapping of his wings proceeds the wind, according to the force of their motion. Surtur, another god or giant, who remains in Muspelheim, is only to appear at the day of destruction. All the monsters are loosed, whom he will lead to the conflict with the Asar, some are killed, but they remain conquerors. After this final combat, Surtur spreads flames over the earth, and all will be consumed. But Naströnd is formed, a place of punishment vast and awful, constructed of serpents, whose venom collects in floods, through which wade murderers, perjurers, and adulterers; but in the plain of Ida, where Asgard formerly stood, another earth will arise from the sea, and says the Völuspá—

> "I see a hall, Brighter than the sun,
> With gold covered, On Gimli's height;
> There will the worthy Princes dwell,
> And without end, Enjoy their honour;"

where Surtur's fire can no longer harm them.

The prose Edda adds, that a man and woman survive, hid in a forest, and fed with dew, who are to replenish the world; and the sun is to bring forth a daughter (the sun is feminine in the northern dialects) more lovely than herself. This seems to be an addition. This Edda, compiled by Christians, has much more of the Christian element than the elder, and is therefore less to be depended on as a faithful transcript of the ancient mythology.

Of the goddesses, besides those mentioned, the most prominent after Frigga, were—Saga (history), a favourite of Odin's; Eir, skilful in the healing art; Gefion, who is a virgin, and to whom belong all who die unmarried; Fulla, also a maiden, the attendant and confidant of Frigga; Freyja (already mentioned) was married to Odhur, who left her, and Freyja wept tears of gold. She bears several other names, which she assumed while seeking her husband, and was the possessor of a famous necklace called Brisinga; Siöfna, who turns the hearts of men and women to thoughts of love; Lofn and Vöra are also deities favourable to lovers; Syn, is door-keeper of the hall of the gods, shutting it against all who have not the right of entering, and likewise presides at trials in which anything is denied on oath; Snotra, the wise and courteous; Gná is the messenger of Frigga, riding a horse on which she glides through the air; Sol, so named by her father on account of her beauty, while her brother he named Mani (moon). This pride offended the gods, who made the sister the driver of the horses of the sun, and the brother those of the moon. There are other goddesses, such as the Valkyrien, who serve the mead in Valhalla, and are sent by Odin to every battle-field to select the slain and to give victory; the Nornen also assist in this latter office. Also, Jörd (the earth), Thor's mother, and Rinda, the mother of Vali, are reckoned among the goddesses.

In Asgard are the twelve heavenly palaces or abodes, of such extraordinary splendour, that the light of the sun or moon was not needed. Asgard is protected by an abyss crossed by a heavenly bridge, strong enough to bear the gods, but which will break under the weight of the giants. This is called Bifröst, and is the rainbow, formed of water, air, and fire, as shown by its colours. The water and air would have been sufficiently strong for the Asar, but the fire was added to guard against the giants. On the boundary between Asgard and Midgard stands Thrudheim, the dwelling of Thor, which forms a thirteenth. The twelve are: 1. Ydali, the valley of moisture, in which Uller, the son of Sif, and the step-son of Thor, dwells. 2. Alfheim, or Elfinland, inhabited by Freyr, the son of Niord, and, according to the prose Edda, by the elves of light (by which is thought to be represented the germinating powers of the sun's rays), who are to exist till the overthrow of the universe, and then to betake themselves to the higher heaven. 3. Valaskialf, Vali's watchtower, in which dwells Vali, the son of Odin and Rinda. Here was also built Odin's chief seat, Hlithskialf, from the elevated throne of which, he and his wife Frigga could overlook the whole world. 4. Söckvabeck (the stream of descent or depth), rushing with cold water, whence Odin and Saga (history) drink every day from golden vessels, and intoxicated with the precious drink, rejoice in the love that may be derived from the water-oracle. 5. Gladsheim (realm of joy), where is Idavölle (the field of business), because here are forged the arms with which the heroes disport. This is the gathering-place of the Asar; here are held the feasts and the combats of the souls of departed heroes who reside in Valhalla; they wander arm in arm with the virgin Valkyrien, whose love and unfading charms are the rewards of those who have received their kiss in battle, the sign of an invitation to the feast of the gods. In Idavölle both Valhalla and Vingolf are situated. The last is the residence of the Einheriar (or heroes), whose help is needed by the gods in their final contest against the inhabitants of Muspelheim, on the destruction of the world. Vingolf is a palace of gold reaching to the clouds. Before the gates of Valhalla lies the forest of Glasir, in which the trees bear leaves of red gold. But Vingolf is the sanctuary of the goddesses, where the half of the slain whom Freyja has chosen are immediately conveyed, while the other half are received by the Valkyrien in Valhalla. Lastly, in Idavölle is the seat of judgment, under the ash Yggdrassil, upon the actions of gods and men. Seats were here provided for the twelve gods already mentioned. In like manner, upon earth, courts of judgment were to be held under a sacred tree and near a sacred well. After having dispensed justice, the Asar ride on splendid horses. 6. Thrymheim (groaning or thunder-home), where dwelt the giant Thiassi, and after his death his daughter Skadi. 7. Breida-blik (world-glancing) the most magnificent of the heavenly dwellings, where is not the least soil, and which is Baldur's residence. 8. Himin-biorg (heavenly palace) on the border of the celestial region, where resides the wise god Heimdall, who is entrusted with the care of the bridge Windhjalm, from being possessed of the Giallarhorn, which is heard throughout the world, from his sleeplessness, and from his wonderfully acute senses; in order that the Asar may not be unexpectedly surprised, one end of this bridge, called Bifröst (rainbow), is close to Heimdall's abode. At the time of the destruction of the world, the invaders from Muspelheim will attempt the passage, the bridge will break or dissolve. 9. Fölknvangr (field of the combatants), the abode of Freyja; a splendid palace, surrounded by a beautiful garden, in which is the hall Sessrumer, wherein the fortunate, who have been selected by the benevolent goddess, enjoy every bliss the world can bestow. 10. Glitnir (splendour), the palace of Forseti, resting on golden pillars, the windows of diamonds, and the roof covered with silver. 11. Nöa-tun (Newcourt), the palace of Niord; and 12. Landvidi (Broadland), overgrown with long grass, that of Vidur.

That under the symbols of these twelve palaces, the twelve months, or the zodiacal signs, are to be understood, there can be little doubt, though it has been controverted, and although we are unable to decide which month or sign the various palaces are meant to represent.

In Asgard the gods had placed their dwellings in the earliest times (Urzeit), and they will all perish in the general conflagration. But this conflagration, though destroying everything, is to give birth to a new creation, in which Asgard will re-appear with increased splendour, and the Asar will revive to resume their original powers. Odin and Thor only will disappear, and the late palace of Odin will become, after this terrific crisis, the abode of Baldur and Hödur. In the first poem, the Völuspá (the decision or judgment of the Veli or prophetess [*]), it is said,—

> "The sun becomes black, The earth sinks in the sea,
> From heaven fall The bright stars,
> A fiery vortex rages round The all-nourishing world's tree,
> The hot flames Lick the skies."

After which the Asar are to reassemble, to find fields that bear produce without sowing, whence everything evil has vanished; and

> "There ride the mighty To the council (or judgment) of the gods;
> The great above all, Who guides all things.
> He decides disputes, Appeases quarrels,
> And ordains for ever His institutions."

Of this "great above all," the 'Hyndluliódh' (the song of Hyndlu) says, after having given a genealogy of the Asar:—

> "Then comes another, Mightier than he,
> Yet him to name I do not venture.
> Few would wish Further to look
> Than when Odin The wolf attacks."

We shall not attempt to give any of the legends incorporated with this system, nor with the esoteric meaning. On the whole it will be seen that the deities are personifications of physical forces and of human passions, fashioned by a northern imagination. J. Grimm, in his 'Deutsche Mythologie,' endeavours to prove that the northern deities are nearly identical with the Greek and Roman and the Hindu deities. There are, necessarily, points of resemblance, but sufficient differences to render the conceptions in each case original.

The Hawamal, or High Song, contains the ethics of the system; there are many striking sayings in it, but we cannot do more than give a specimen:—

> "With his weapon No one should part
> In the open field;
> No one knows, How soon on the way
> He may need his spear."
>
> "Moderately wise Should a man be
> But not too wise;
> The heart of the wise Is seldom serene
> If it becomes too wise."

For a fuller investigation we may refer to Jacob Grimm's 'Deutsche Mythologie,' 1854; Karl Simrock's 'Die Edda, die ältere und die jüngere,' 1855; and 'Das Mythologische Handbuch,' 1853; L. Uhland's 'Sagenforschungen. Der Mythus von Thor,' 1836; Berger's 'Nordische Mythologie,' 1834; Dr. J. C. Bauch's 'Nordische Mythologie,' 1847; Rask's 'Snorra Edda, ásamt Skalda ogtharmeth fylgjundi Ritgjorthum,' Stockholm, 1818; various papers by Uhland, Dietrich, Müllenhoff, Grimm, and others, in 'Zeitschriften für Geschichtswissenschaft;' Mannhardt's 'Germanische Mythen;' W. G. Frye's 'Trois Chants de l'Edda,' Paris, 1844; and Mallet's 'Northern Antiquities,' edited by I. A. Blackwell, 1847.

SCANTLING, a term used by carpenters to express the transverse dimensions of a piece of timber; and also in some cases as a general name for small timbers, such as the quartering for a partition, rafters, purlins, or pole plates in a roof, &c. All quartering or squared timber under five inches square is designated scantling. [TIMBER.]

In masonry the same word is used to express the size of stones in length, breadth, and thickness.

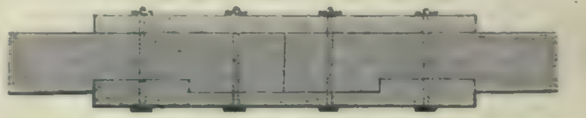
SCAPEGOAT, or AZAZEL (עֲזָאזֵל). On the great day of atonement among the Jews, the high-priest was to choose two goats, and after presenting them before the Lord at the door of the tabernacle, he was to cast lots upon them, one lot being for the Lord, and the other "for Azazel." The one upon which the Lord's lot fell was to be sacrificed as a sin offering, and the other was to be presented alive before the Lord to make an atonement with him, which was done by the high-priest laying both his hands on the head of the goat, and confessing over him the sins of all the people, which were thus said to be "put upon the head of the goat." The goat was then to be sent away into the wilderness by the hand of a fit man, who was to let him go in the wilderness. (Levit., xvi. 8-28.)

The meaning of the word *Azazel* is very doubtful. It seems to be derived from a root (which still exists in Arabic) meaning *to separate*. 1. The common interpretation refers it to the goat itself as being *sent away*. 2. Some take it to be the place to which the goat was sent, as being either a proper name, or merely a general term for a *separate place* or wilderness. 3. Spencer and most of the German critics consider it to be the name of an evil spirit, who was supposed to inhabit desert places; and they would translate Levit. xvi. 10, "to let him go *to Azazel* (instead of, *for a scapegoat*) into the wilderness." 4. It is maintained by Hengstenberg and others, that Satan is typified by the goat, the separated one, and this view seems corroborated by the passage in Zech. iii. Representing the sins of the people, which are upon repentance to be forgiven, he is driven away into the desert. It is also considered to be typical of Christ, so far as a vicarious atonement is to be accepted under certain conditions for committed sins.

SCARFING, the mode of joining two pieces of timber end to end, in such a manner that they may appear but one, and cannot be pulled asunder by a force applied in the direction of their length, without breaking off part of the wood at the joint.

Other modes of uniting two timbers into one continuous length are sometimes practised; as for instance, the simple plan called *fishing* a beam, in which the ends abut against each other, and pieces of wood are added on each side, as shown in *fig.* 1; the whole being held together by iron bolts. The strain on the bolts may be reduced by indenting the pieces added at the joint into the beam, as represented in the lower part of the figure; or by transverse keys of hard wood driven into grooves, of which one-half is cut in the beam, and the other in the supplementary pieces, in a similar manner to those shown in *fig.* 6.

Fig. 1.



Where neatness is more essential than strength, scarfed joints are preferred to any arrangement of this kind, because a beam united by them is of the same breadth and depth at the joints as at other parts. *Figs.* 2 and 3 represent two of the simplest forms of scarfing, in both of which the strain is borne wholly by the bolts. It is advisable to add a plate of iron on the faces of the beam where the heads and nuts of the bolts pass through, and the ends of these plates may be turned into the wood, as shown in the cuts. Of these two plans the first appears rather preferable, because the screwing up of the bolts has no tendency to alter the position of the parts; while in the second it has a tendency to make the inclined faces slide upon each other, and thereby to open the joint.

Fig. 2.

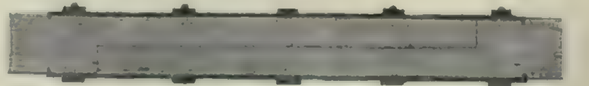


Fig. 3.

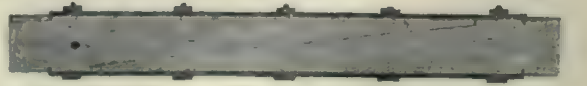
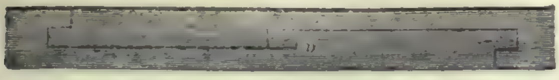


It is desirable to avoid depending solely upon bolts for the strength of a scarf, owing to the effect of the shrinking of the timber, and the liability of the bolts to be, in consequence of their small dimensions, pressed into the wood. *Fig.* 4 is a scarf that may be used without

---

[*] The form of the word is perhaps deserving of a notice, as giving the origin of the Scottish word *spae*, to foretell; and *spaewife*, a fortune-teller.

Fig. 4.



bolts, although the addition of them adds much to the security of the joint. In this plan a key or wedge is driven gently into the square space at *a*, to bring the parts into their places. Two other illustrations will suffice to explain other varieties of scarfing. *Fig.* 5 is a diagonal scarf, in which the parts are said to be *tabled* together; they being so cut and fitted to each other that no force can separate them longitudinally, without breaking, so long as the bolts hold them together sideways. *Fig.* 6 shows a very simple and good plan of scarfing, which is easily executed with accuracy, owing to the absence of oblique faces. In this arrangement keys are used to resist any force tending to separate the beam in the direction of its fibres, instead of the parts being tabled together. The ends of the keys, which should be of hard wood, and let into both pieces of the beam to an equal depth, are shown by the dark tint in the cut.

Fig. 5.

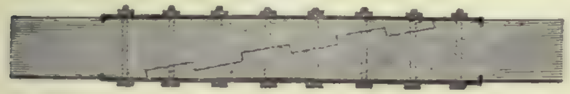


Fig. 6.

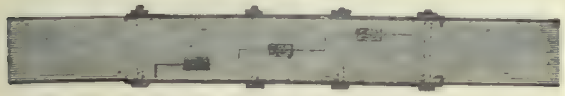

Varieties may be almost infinitely multiplied by increasing the number of the faces, whether oblique or square, and uniting the parts either by tabling, keying, or a combination of the two; but in most cases the greatest simplicity should be aimed at, in order that the parts may the more readily be made to fit each other with accuracy. Very complicated scarfs have been used by some old carpenters, respecting which Robison observes that "many seem to aim at making the beam stronger than if it were of one piece;" an absurdity too manifest to need refutation. Where a scarfed beam is exposed to transverse strains, the joint should be varied from the ordinary form; but for these and some other contrivances to meet peculiar circumstances the reader is referred to the practical works of Tredgold, Nicholson, &c. When a piece of timber subject to compression in the direction of its length has to be scarfed, oblique faces should be avoided, because of their tendency to slide upon each other. Though bolts are commonly used to secure scarfed joints, iron hoops or straps, driven on tightly, have been recommended in their stead, and possess the advantage of not weakening the timber. In joints that depend wholly on bolts, Tredgold recommends that the sum of their areas should never be less than two-tenths of the area of the section of the beam. From the same authority we give the following rules for the length of scarfs:—

In oak, ash, or elm, the whole length of the scarf should be six times the depth or thickness of the beam, where there are no bolts.

In fir, without bolts, twelve times the depth.

The whole length of a scarf dependent wholly upon bolts should be in oak, ash, or elm, about three, and in fir, six times the depth of the beam.

When bolts and indents are used together, the length of the scarf may be, in hard woods, twice, and in soft woods four times the depth.

SCARIFIER. [ARABLE LAND.]

SCARLATINA (originally written Scarlattina, from *scarlatta*, a red-coloured cloth), Scarlet fever. This disease was not distinguished by the ancients from any of the other eruptive fevers; they contented themselves with classing together all these fevers as pestilential, and they attributed the variety of eruptions that accompanied them to different combinations of the humours. Small-pox, measles, and scarlatina were described by the Arabians, but they looked upon them merely as varieties of the same disease, and even to the close of the 18th century the two last-named maladies were confounded. Dr. Withering, in a second edition of an essay which he published on scarlet fever, in the year 1793, first pointed out its distinctive characters.

Scarlatina, like small-pox and measles, may appear as an epidemic, or it may be propagated by a specific contagion; as an epidemic, it most usually appears at the latter end of the summer and the beginning of autumn; sporadically, it is met with at all seasons; it further resembles the diseases we have just named in rarely attacking twice the same individual. Scarlatina varies much in severity, from the mild febrile disturbance which has been pronounced by Sydenham to be fatal only through the officiousness of the doctor, to that grave form of the disease which has received the appellation of malignant. This difference has given rise to its division into three species, the *Scarlatina simplex*, *S. anginosa*, and *S. maligna*. Scarlatina is ushered in by rigors, followed by increased heat of the body, thirst, loss of appetite, and all the symptoms of inflammatory fever. On the second day of this fever, or somewhat later in the severer forms of the disease, patches of a scarlet-coloured efflorescence begin to appear on the face and neck, which extend downwards, and, coalescing, soon spread over the whole body. On the trunk, however, the rash is seldom uniform, but is distributed into diffuse irregular patches, the scarlet hue being most vivid about the flexures of the joints and on the loins; occasionally minute vesicles are visible, and Sauvages has considered this circumstance sufficient to constitute a distinct species, which he calls *S. variolodes*. On the third and fourth days the eruption is at its height; even the mouth and fauces are not free from it, the papillæ of the tongue are unusually red and elongated, and the face is generally more or less swollen. On the fifth day it begins to decline, disappearing by interstices, so that the patches reappear as at the commencement, and it is generally gone before the end of the seventh. Between the eighth and twelfth days the cuticle comes off in the form of a scurfy desquamation, and the fever has subsided. This is the course of *Scarlatina simplex*. At those periods of the disease when the eruption is in patches, scarlatina is apt to be mistaken for measles, but it may readily be distinguished from the last-named disease by the following signs:—In measles, the patches are of a rosy hue, of a crescentic form, and elevated above the surrounding skin; in scarlatina they resemble more the colour of boiled lobster, want the crescentic shape, and the hand passed over them detects minute asperities, but no elevated patches. It is further distinguished from measles by the greater heat of skin, the temperature being sometimes as high as 108° or 112° of Fahr., by the absence of catarrhal symptoms, and by the state of the papillæ of the tongue.

Roseola is the name of an affection which is characterised by an eruption bearing some resemblance to scarlatina; but it is of a more crimson colour, pursues its course in a direction contrary to that of scarlatina,—namely, from the extremities and trunk to the neck and face,—and is attended with less constitutional disturbance.

Scarlatina accompanied with sore throat—*S. anginosa*, or *cynanchica*, as it is termed—is a much more frequent and severe form of the disease than that which we have just described. Not only are the precursory febrile symptoms more violent, but the whole course of the malady is protracted; the eruption is seldom so universal as in the simple variety, but is in scattered patches, which frequently vanish and reappear; the interior of the mouth and fauces is of a high red colour, tumefied and painful; superficial ulcerations not unfrequently form on the tonsils, uvula, and soft palate; and the throat is much clogged up with a tough viscid phlegm. In *S. maligna* the fever is of a typhoid character; the pulse is small and feeble; the tongue and lips dry, and encrusted with a brown fur; there is delirium alternating with coma, and the rash is faint and continually coming and going; the ulcers in the throat are covered with dark-coloured sloughs, and a large quantity of viscid mucus clogs up the fauces and impedes respiration and deglutition. These symptoms are often accompanied by diarrhœa, and by petechiæ on the skin, with hæmorrhage from the nose, throat, bowels, or other parts, which generally lead to a fatal termination: this may occur on the third or fourth day of the disease, or the patient may linger to the second or third week; if recovery take place, it is exceedingly tedious. It has been observed that during the prevalence of scarlatina adults are not unfrequently affected with the efflorescence in the mouth and throat, without the skin participating in the affection. For this class of cases Dr. Tweedy has proposed the name of *S. faucium*. All the varieties of scarlatina that we have mentioned may be observed during the prevalence of the same epidemic, and even among members of the same family; but it is no less true that each epidemic has generally a certain character or type, which it is important to ascertain in order to regulate the treatment. This circumstance renders it difficult to come to any just conclusion as to the mortality from this disease.

The reports of the Registrar-General for 1858 and 1859 show the mortality in London from scarlatina as compared with other forms of zymotic disease:—

Diseases.	1858.	1859.
Scarlet fever	4118	4197
Small-pox	247	1156
Measles	2383	1305
Hooping-cough	2700	1741

Scarlet fever visits certain districts as an epidemic, and that whilst in some years it falls down to a level with other diseases of the same general nature, or even below them, it rises at others far above them. During the years 1857, 58, 59, and 60, scarlet fever has prevailed in London as an epidemic, and has carried off little short of 12,000 persons. During these years it has been associated with the disease called diphtheria, but they are distinct diseases and not in any manner produced by the same causes. [DIPHTHERIA.]

Scarlatina is often followed by other forms of disease. One of the most frequent of these is anasarca, which frequently terminates fatally.

This disease arises from the morbid condition of the kidneys. In a large number of cases of scarlatina the kidneys are primarily affected, and the urine presents a low specific gravity, and contains albumen. In the anasarca which comes on after the febrile symptoms have passed away, there is invariably present albuminuria. This condition of the system often terminates fatally by dropsical effusions occurring in the pleura, the pericardium, or the membranes of the brain. It sometimes happens that an attack of scarlet fever may not obviously produce the usual skin and throat symptoms but expend all its force on the internal organs, especially the kidneys. Under these circumstances anasarca may come on and lead to a fatal result.

Amongst other sequelæ or results of the action of the scarlatinal poison is an extension of the inflammation of the throat into the eustachian tube, and the internal ear. In this way the bones of the ear are destroyed, and ulceration of the tympanum and its destruction follow. Fœtid discharges take place, and the whole of the internal ear not unfrequently becomes involved, producing, should the inflammation not extend to the brain and destroy the patient, permanent deafness.

In other cases an affection of the joints, not unlike rheumatism, comes on during the attack of scarlet fever. This affection of the joints continues sometimes a long while after the active symptoms of the fever have disappeared.

Scarlatina is an example of a contagious and infectious disease. In the majority of cases the origin of the disease can be traced to exposure to the poison arising from a previous case. The intensity of the poison seems greater than even that of small pox or typhus. Dr. Watson says, "it lurks about an apartment, or clings to furniture and clothes, for a very long time, even after some care has been taken to purify them. Of this I have known several remarkable examples. You will be asked at what period the danger of imparting the disease on the one hand, or of catching it on the other, is over; and I would recommend you to answer that you do not know. I am sure I do not." Many persons go through life without catching this disease, and it is most desirable that all should. The only certain way of avoiding it is the strictest quarantine. Any thing which has been near the patient, or handled by persons attending upon the patient, may communicate the disease. The only certain prevention of its spread in families is either the removal of the sick or those liable to take the disease. The spread of the scarlatinal poison is not dependent on dirt and squalor, and other circumstances injurious to health, although the fatality of the disease is greatly increased by these circumstances. The disease is generated and spread by the poison alone. It is on this account that the greatest attention should be paid in nursing this disease to prevent infected things from passing out of the patient's bedroom. All linen or clothes worn by the patient should be immediately after they are used placed in boiling water. All vessels used in the bedroom should be immediately emptied after they are used, chlorinated lime or soda, or the permanganate of soda, being added to their contents. The vessels should also be washed and rinsed out with solutions of these substances. After the patient has recovered, every thing in the room that can be placed in boiling water should be submitted to its action, and books, papers, and things which will not bear water, should be placed in an oven. The room should be fumigated with chlorine, and the walls and ceiling whitewashed.

In the treatment of scarlatina it should be remembered that in the milder cases little or no medicine is required. The patient passes through all stages with little derangement of the system, and the only thing required is to prevent exposure to cold, and to watch for the accession of any of the symptoms of the sequelæ above mentioned. When the symptoms are more severe an alkaline treatmemt may be recommended. Dr. Watson especially recommends the chlorate of potash with hydrochloric acid. When the throat symptoms are severe in adults, leeches to the throat or cupping at the nape of the neck have been strongly recommended. Some practitioners recommend, in cases of a low type, small and often repeated doses of sulphate of quinine. Where the pulse is rapid and the tongue becomes dark, the administration of wine is indicated, and where wine fails to stimulate sufficiently, brandy has been given with advantage. The sesquicarbonate of ammonia, in cases with low symptoms, has been vaunted as a specific: it may be given with advantage in cases in which wine is indicated. Purgatives and saline diaphoretics may be administered as the symptoms indicate. The throat demands especial attention: where the tonsils are merely swollen a gargle of alum or powdered alum may be applied. When it is ulcerated the ulcers may be touched with nitrate of silver or a lotion applied. The chlorate of potash, with nitrohydrochloric acid, may be used as a gargle. Where the ulcerations are fœtid, syringing the throat with a lotion of chlorinated lime or soda will greatly contribute to the comfort of the patient. There is no one system of treatment that is adapted for all cases, and those writers who advocate one system can have had but little experience of the great variety of forms which the disease presents.

The treatment of the anasarca and other sequelæ will depend on the symptoms present. When dropsical effusion comes on, the patient will bear more active treatment than in the primary and secondary stages of the disease. Cupping or leeches to the loins is of service, and active purgatives. The chlorate of potash may be continued in this form of the disease, and when the more formidable symptoms are subdued, the salts of iron may be administered.

SCARLET DYE. [Calico Printing; Cochineal; Dyeing.]

SCARLET FEVER. [Scarlatina.]

SCENE PAINTING. With respect to the stage of the ancient theatres very little is known, and even that is exceedingly indistinct, being founded not upon description, but merely on incidental allusions. But granting that they employed some kind of temporary stage decoration suited to the subject of the piece, the presumption is that it did not at all resemble our modern scenery. The width of their stages renders it difficult to understand how any scene painted upon a single piece of canvas of sufficient size could have been let down, or rather drawn up, as it is supposed the *aulæa* were, or otherwise changed during the performance; and it is quite certain that, since the performances took place in the open air and by daylight, however contrived or executed, any kind of scenery like that of our modern theatres could not have produced the same degree of illusion.

With the rise and progress of scene-painting and stage-effect in modern times we are not much better acquainted, since no specimens of early scenery have been preserved, and only scanty, casual, and fragmentary notices relative to it have come down to us. From what is recorded of Baldassari Peruzzi's [Peruzzi, in Biog. Div.] works of this class, and those of some other artists, it would seem that scene-painting was very greatly improved, though it may not have been brought all at once to perfection, about the time of Leo X. Considerable improvement appears also to have taken place in the general economy of the stage and everything connected with scenic apparatus, as well as in scene-painting. For much of his reputation with his contemporaries Inigo Jones was indebted to the fancy and talent he displayed not merely as a scene painter, but in getting up pageants and masques, and planning the decorations and machinery for them. But with respect to the nature of his scenic effects and contrivances, we have little more than traditional report to depend upon, for there exists no history of theatrical painting and of the various improvements which have from time to time taken place in the decorations and apparatus of the stage.

Of this last, and of the quantity of hidden machinery requisite for expeditiously changing the scenes, as well as for effecting more complex displays in pieces of *spectacle*, we shall not here speak, but confine our remarks to the painted scenery alone. Beginning with what is technically termed the *drop-scene*, as being the simplest of all, we have merely to remark that it is no more than a picture or single painted surface let down by way of blind or curtain between the acts, so as to close up the opening of the proscenium. As it generally continues to be used for an indefinite time—thirty or forty years in some instances—the drop is more carefully executed than back scenes, which, showy as they may be in effect, are required only for a season, and are at a much greater distance from the spectators. As far too as pictorial effect and truth of perspective are concerned, a drop shows itself to far greater advantage than other scenery, which is composed of different pieces constituting what is called a set of scenes. These consist of the narrow upright pieces called *side-scenes* or *wings*, of the narrow horizontal ones (*hanging-scenes* or *soffits*, painted to imitate a sky or ceiling, but chiefly intended to screen the space over the stage), and of the *back-scene*. Backs again are of two kinds, namely, *rolling* scenes which are let down from above, and *flats*, which are formed of two sliding scenes strained upon framing, like the wings, and meeting each other and uniting in the centre. These are employed when what are termed *practicable* scenes are required, that is, with doors, windows, &c., which admit of being used as real doors, &c.; or else when there is occasion that the "flat" should suddenly open and discover another scene behind it. In addition to these, there are what are termed *open* flats, which are scenes cut out in places so that both the background is seen and the actors can pass through them. They are commonly used for the representation of groves or forests, but sometimes for interiors with open arches. There are besides what are technically known as *pieces*, narrow scenes placed obliquely on one side of the stage when it is wanted to show a cottage or corner of a house, with a *practicable* door in it. Lastly, there is *set scenery*, as it is termed, where, instead of the usual wings ranged one behind the other, there is a single scene on each side extending from front to back, so that the stage is completely enclosed. By this means a more perfect representation of a room can be obtained than where wings are employed.

In fact side-scenes or wings can be regarded as little better than so many detached screens absolutely necessary to shut out from view the space on each side of the stage, since in themselves they rather detract from than at all aid illusion and effect; more especially in interiors, where what should represent a continuous wall or surface on either side is broken into several pieces, which are besides placed parallel to the back scene or flat, instead of being at right angles to it. If the scenery be viewed exactly from the centre and from the true perspective distance, the defect thus occasioned is not very striking or offensive; but if the spectator be near to the stage, or placed on one side of the house, the whole becomes more or less distorted, and the wings appear to be only so many disjointed fragments, so that all scenic illusion is destroyed.

Scene-painting is executed in *distemper*, that is, with colours mixed up with size, the design being first made in a sketch, which is accurately laid down to scale, and from which the perspective outlines are transferred to the larger surface. Instead of beginning with dead colouring and then gradually working up his picture, the artist puts in all his effects at once, (as in fresco-painting)—the full tone of the lights and shadows, finishing as he proceeds, and merely retouching or glazing those parts afterwards which require additional depth or brilliancy. In this kind of painting, *bravura* of execution and strikingness of effect are indispensable, and nature must be rather exaggerated than the contrary; at the same time care must be taken lest mere gaudiness be substituted for brilliancy and richness. Further, as much of the costume of the piece depends upon him, it is important that the scene painter should not only be skilled in architectural delineation, but also well informed as to the styles of different countries and periods, so as to avoid those errors and anachronisms which are frequently committed, and which are sometimes so glaring that no beauty of execution can atone for them.

Much of the effect of scenery depends upon a skilful mode of lighting it; in which respect considerable improvements have taken place of late years, and the light is now occasionally thrown from above, as well as from the sides and the foot-lights, coloured glass and other contrivances being also occasionally employed. A variety of mechanical contrivances have indeed been brought to great perfection so as to imitate particular effects in the most deceptive manner, such as those of moonlight, where the moon breaks through the clouds and gleams upon water, &c., changes of the sky from clear to stormy, or the contrary, the sudden glare of fire, &c.; the most elaborate and costly combinations of mechanical apparatus with carefully painted scenery are now exhibited in the "transformation scenes" of Christmas pantomimes and extravaganzas.

Though looked upon as a very subordinate branch of the pictorial art, many artists of superior ability have applied themselves to scene-painting. To the name of Peruzzi we may add those of Bibiena, Servandoni, Loutherbourg, Lambert, Rooker, Gonzago, Quaglio, Sanquirico, Stanfield, Roberts, Grieve, and Beverly.

SCEPTIC (Σκεπτικός), one who doubts, who deliberates, who circumspects. Such is the primary meaning of the word, but like most words it has been wrested from its primary signification by ignorance or prejudice, and is now, beyond its philosophical meaning, used to express a dissenter from an established religion. In one sense it denotes a philosopher; for doubt is the first step in science; it is the refusal to take for granted any explanation of phenomena that may be offered, and the *circumspection* of the grounds and truth of this explanation. In common usage, Sceptic denotes, loosely enough, an atheist, deist, pantheist, &c., or, more precisely, the holder of any heterodox opinions. Common usage is here, as is usually the case, wrong. To set the matter in its true light, we must remark that scepticism is simply doubt, while heterodoxy is disbelief; something manifestly distinct from doubt, which is a mere oscillation of the mind between opinions; the belief of this moment passing into the contrary belief of the next; whereas disbelief is the belief in something contradictory. Reid, and others of the Scotch school, class disbelief as an independent power of the mind, equally with belief. We hold that the two are one and the same power exercised on contrary opinions. The mind must believe a thing or disbelieve it (that is, believe something else which is contradictory), or must oscillate—one moment believing this thing, and the next believing another thing. If then this distinction be borne in mind—if we have rightly demarcated doubt from disbelief—the erroneous application of sceptic in common usage will be obvious. An unbeliever and an infidel are convertible terms in ordinary language; but nothing can be more erroneous. An unbeliever, in a positive sense, is the believer in some *other* religion, and as dogmatic in his belief as the most orthodox (and hence the early Christians were called atheists by the Greeks, because they disbelieved in *their* gods), and might turn round upon the orthodox believer with the charge of unbelief in *his* religion. Thus a Mohammedan is an unbeliever to the Christians, and *vice versa*. An *Infidel*, on the other hand, as the word implies, is one with no belief, a doubter, a sceptic. The Infidel, when truly such, does not dissent because he believes something else—not because he has a contrary faith—but because he cannot believe for any length of time either the one or the other; he oscillates between them This last is the true sceptic; this he always remains; he doubts, he deliberates, he circumspects to the last day of his existence: as soon as he ceases to doubt, deliberate, and circumspect, and takes up a distinct faith his character as a sceptic vanishes; he becomes a believer. When considering the great and awful subjects of religion or philosophy, the weakness of the human mind must ever keep it in this state of scepticism, when once it has renounced its faith in things higher than its own logic,—when once reason is set up as the standard, measure, and exponent of all things, the human being is lost in the shoreless sea of scepticism.

In one sense, there are few who are not sceptics on certain points and on the other hand, few who can properly be designated as sceptics; for to deserve this they must *continue* in the state of doubt which admits of no affirmation. Most men begin, as was said of Descartes, in doubting everything, and end in believing everything. The few who have consistently preserved the character of sceptic have been among the most celebrated in the history of philosophy. [SCEPTICISM.]

SCEPTICISM (Σκέψις), doubt, deliberation, circumspection. There are two significations to this word: the one denoting doubt of *an* explanation of phenomena; the other the more precise indication of a certain class of philosophers who have *continued* sceptics, whose system of thought in its fundamental points ever remained sceptical. To this latter we alone direct ourselves.

Socrates has been commonly called the founder of this sect by the enunciation of his famous tenet,—all he knew was that he knew nothing. But this was more a limitation of the confidence of the Dogmatists and Sophists, and a confession of the weakness of the human understanding, than any fundamental scepticism, such as was subsequently embraced by Pyrrho and others; for though Socrates, more occupied with pulling down than building up, advanced few speculative opinions of his own, yet we agree with Schleiermacher in awarding to him the merit of having first posited the true idea of science (as the intercommunion of dialectics, physics, and ethics); and this one positive principle in his philosophy is sufficient alone to demarcate him from the sceptics. As well might Bacon be accused of scepticism, his position in the 'History of Philosophy' being very similar to that of Socrates. How different this is from the scepticism of Pyrrho, whose whole philosophy consisted in a suspension of judgment, or perpetual negation [PYRRHO, in BIOG. DIV.], may be seen by a comparison with some definitions of scepticism by the philosophers themselves. Sextus Empiricus, the historian of the sect, defines it as "the power (δύναμις) of opposing in all their contradiction the *sensuous representations* and the *conceptions of the mind* (φαινόμενα τε καὶ νοούμενα), and thus to induce perfect suspension of judgment" (Sextus Emp. 'Pyrrho. Hypot.,' i. 1, 4); and Carneades denied the possibility of real knowledge of anything from the twofold relations of the representation (image-idea, φαντασία) to the object (τὸ φανταστόν), and to the mind (ὁ φαντασιούμενος), as the mind had no criterion of the truth: all that could be affirmed was the mere probability (τὸ πιθανόν). Ænesidemus defines it as the recollection of opinions from the testimony of the senses or other evidence, by which means one dogma was opposed to another, and upon comparison all found useless and confused. (Brucker, 'Instit. Philos.,' ii., c. 14, § 7.) From the fallaciousness of sense, the differences of sensuous perceptions in different organisations, the weakness of understanding, and the impossibility of diving beneath the appearances to the real causes of things, the sceptics deduced a system of indifference which became equally difficult to accept or refute. They maintained that every proposition requires a prior proposition to support it, and so on *ad infinitum*; or else it assumes some axiom which cannot be proved, and is to be taken for granted without demonstration, and consequently may be denied with the same force with which it is assumed. Further, that nothing can be known by means of itself, nor by means of something else, whilst that other remains unknown, and that other must either be unknown or known by means of something else, and so on *ad infinitum*. (Sextus Emp., i. 15.) This last is extremely subtle, and in itself is irresistible; but as Kant profoundly remarked, there is this fundamental flaw in absolute scepticism, "that it gives out everything for appearance. It therefore distinguishes appearance from truth, and of course must have a mark of distinction; consequently presupposes a knowledge of the truth, thus contradicting itself." The careful avoidance of any expression savouring of certainty—the using of the term *seems* for *is*—which was adopted by this sect, has been inimitably ridiculed with all his wit and vivacity by Molière ('Mariage Forcé,' act. i., sc. 8); and indeed a system so unsatisfactory never could and never has taken much root except in minds of a very peculiar and indolent nature. The abnegation of man's proudest faculty, reason, the perpetual indecision on every point, so little accords with the fertile and prodigious activity and creative power of the mind, that the real professors of scepticism have been universally indolent, easy-natured, sensual men, with whom the speculative doubting was stimulus enough. Morhoff ('Polyhistor,' ii., lib. i., c. 6, and l. ii., c. ix.) gives an account of all the sceptical writers in his dull laborious way; Brucker and Endfield ('Hist. of Philos.,' i., b. ii. c. 16) give a more detailed account of their tenets. [PYRRHO, in BIOG. DIV.]

Of modern scepticism it is remarkable, that it differs little from the ancient, and that whatever strides philosophy may have taken in other departments, it has made little or none in that of doubt. The same clenching subtle arguments occurred to a Theætetus as to a Hume. However we will proceed to give a brief historical account of the attempts made to revive it.

Sanchez, a Portuguese physician, published in 1581 a treatise entitled 'De multum nobili et primá universali Scientiâ quod nihil scitur' (on the excellent and first universal science that nothing is known), a rare and extraordinary work, containing the leading arguments of the sceptics propounded in an extravagant manner; but after many sweeping assertions on the impossibility of all science, he at last admits the possibility of truth, and hints very plainly that he himself has attained it. It is an evidence of the restless spirit of the times and the growing servility to the authority of Aristotle and his followers. But nothwithstanding his natural confidence in his own exclusive perception of truth, Sanchez was a real sceptic. Jerom Hernhaym, an abbot of Prague, on the other hand, who wrote a work De Typho Generis Humani' (on the vain glory of human nature), in which he endeavours to expose the falsehood, presumption, and uncertainty of human science, is to be distinguished from Sanchez and the Pyrrhonists; he was a pseudo-sceptic, and his evident design was to depreciate human learning as inimical to divine wisdom, and to lead men wholly to rely upon religious faith.

Of a similar tendency is the celebrated work of Bishop Huet ('Essai sur la Faiblesse de l'Esprit humain'), in which, after exhibiting the principal points of the sceptic philosophy as given in Sextus Empiricus to prove the insufficiency of human knowledge, he falls back upon the consequent necessity of retiring within faith and being content with it. So palpable is the pretence of his scepticism, that besides being a devout and learned bishop, he was the author of 'Demonstratio Evangelica.' Yet with singular inconsistency he addressed this demonstration to the very understanding which he had so triumphantly asserted could *not* attain truth.

Bayle is, as Cousin remarks, the ideal of sceptics. [BAYLE, in BIOG. DIV.]

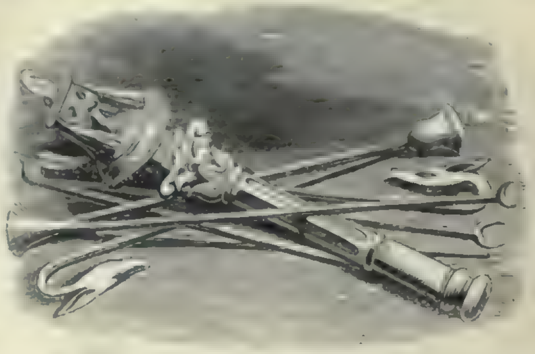
Glanvill, whose 'Scepsis Scientifica, or Confest Ignorance the way to Science,' "has hardly," says Hallam, "been seen by six living persons" (Hallam, 'Lit. of Europe,' iv.), is the systematic sceptic of the 17th century, and his work is altogether a curiosity from the rarity of its notice, the extraordinary nature of its contents, and from its author having been a clergyman and member of the Royal Society, and from his having one year afterwards published a book in favour of witchcraft. [GLANVILL, JOSEPH, in BIOG. DIV.]

Bishop Berkeley, so commonly classed with the philosophical sceptics upon that misconception of the term we have before adverted to, is to be regarded simply as a believer in another system of philosophy from that usually accepted. He denied the existence of an external world. [BERKELEY, in BIOG. DIV.]

Hume was the greatest and the legitimate sceptic of the 18th century. His was genuine Pyrrhonism. He attacked the very foundations of our knowledge by contrasting with them their self-contradictions. "The truth is," observes Dugald Stewart, "that whereas Berkeley was sincerely and *bonâ fide* an idealist, Hume's leading object was plainly to inculcate *universal scepticism.*" ('Essays,' ii., c. 1.) Hume accepted Berkeley's arguments in disproof of external reality, but he went still farther; after denying a *substantive world* (consciousness being concerned only with ideas or representations), he denied on the same ground a *substantive mind*. For, he asks, as we know but impressions and ideas, how can we know that there is anything *more* than these? These are the substance and limit of our knowledge. The mind itself has no distinct, energetic, *substantive* existence—it is but a *succession of ideas.* This is the doctrine expounded by Theætetus the Sophist, in Plato: "there can be nothing true, nothing existent, distinct from the mind's own perceptions" (*τὰ φαινόμενα ἑκάστῳ ταῦτα καὶ εἶναι*). In truth the assumption of an external reality upon any grounds hitherto proposed is gratuitous and questionable. In the fact of perception it is assumed that there is—1, the consciousness; and, 2, the exciting external cause. But upon a patient and rigid interrogation of consciousness, all we find in it, as a fact, is a change in our state of being; beyond this no other element is *given*, but *assumed.* Now the question can never be—whether we *are* conscious of a change of being (since change is the condition of consciousness, and the individual consciousness is proof of itself), but whether, as the sceptic requires to know, we have or can have any *knowledge* or *consciousness* of this external exciting cause in itself. This we must give up. It being admitted that we are influenced by externals mediately (that is, in *representation*), therefore our consciousness is of the *ideas,* not of the *objects themselves.* All that we really know is our own consciousness—our change of being—but we remain ignorant whether that change proceed from an *evolution of being itself*, or from the correlation of being and an external object. The reasonings of Reid, Stewart, Brown, &c. against this doctrine are most puerile. Stewart alone seems to have comprehended it in some of its aspects, but he nowhere fairly exposes and refutes it. If Hume is to be refuted, it must be, as Kant plainly saw, by a reconsideration of the very elements of perception, and an investigation of the received doctrines which Hume, assuming as established, employed as first principles. This was the work of Kant.

Comte, though he calls his system positivisme [COMTE, in BIOG. DIV.] may be considered a sceptic in its modern sense. Nothing, according to him, can be believed that cannot be proved; so he discards all that is accepted as revealed as wholly unestablished, and nothing but the positive facts of physical science are admitted. His own notions of a new religion require a far greater amount of belief than the system he attempts to discredit.

SCEPTRE, from the Greek *skeptron* (*σκῆπτρον*), a staff, or rod carried by princes as the ensign of judicial and sovereign power: whence in the Old Testament (Numbers xvii. 2), and in Homer the most solemn oaths are sworn by it. In the Persepolitan sculptures the sceptre figures as a long walking staff, and in the sculpture found at Nineveh by Botta and Layard, the great king is sometimes represented carrying a similar long staff; but the sceptres borne by the royal sceptre-bearers (and Xenophon mentions that Cyrus was always attended by 300 sceptre-bearers), are shorter and more ornamented. Among the Egyptians sceptres were also much ornamented; of their appearance the following group will give a notion.



The reader who desires to know the different forms in which the sceptre is represented upon ancient coins, may consult Rasche's 'Lexicon Rei Nummariæ,' v. 'Sceptrum.' Le Gendre tells us ('Nouvelle Histoire de France,' 8vo, Paris, 1719, tom. ii., p. 116) that with the kings of France of the first race the sceptre was a golden rod as tall as the king himself. The sceptre, as an ensign of royalty, is of greater antiquity than the crown.

SCHEELE'S GREEN. [COPPER.]

SHILLING. [MONEY.]

SCHISM, SCHISMATICS. The Greek word *schism* (*σχίσμα*) is used several times in the New Testament in its literal sense of a rent or rupture *in one and the same object* (Matt., ix. 16; xxvii. 51; Mark, i. 10; ii. 21; Luke, v. 36; xxiii. 45; John, xix. 24; xxi. 11); and also in a figurative sense for a division of opinion among a number of persons considered collectively as constituting a whole (John, vii. 43; ix. 16; x. 19; Acts, xiv. 4; xxiii. 7). In reference to the Christian church, *schism*, in the abstract sense, is never mentioned. *Schisms* are spoken of twice only (1 Cor., i. 10; xi. 18); and in a third passage, where the union of the members of the church is compared to that of the parts of the human body, the object of this union is stated to be, "that there should be no *schism* in the body." (1 Cor., xii. 24-26.) From a comparison of these passages, it clearly appears that *a schism*, in the New Testament sense, does not imply the open separation which exists between Christians and unbelievers, nor that between the members of different Christian communions, but it denotes something existing within one and the same church; and further, it does not appear to designate any difference of opinion respecting doctrines or ceremonies or forms of government, but rather to refer to a state of mind, to the absence of a spirit of united Christian love. ('Dissent not Schism,' a discourse by T. Binney.)

The common use of the word in ecclesiastical writers is different from this. With them *schism* is nearly synonymous with *separation*; but in its stricter use schism is a separation from the communion of a church on the part of certain of its members who do not differ from its other members on any point of religious doctrine. *Heresy* consists in a dissent from the *doctrines* of a church; *schism* is a dissent from its *government*. From this definition it clearly appears that any attempt to enumerate the schisms of the Christian church would be fruitless, since every community is considered schismatical by all the rest.

The event which ecclesiastical historians call *the great Schism of the West* occurred in the 14th and 15th centuries. After the death of Gregory XI. (A.D. 1378), the cardinals, being compelled by the clamour of the people of Rome to elect an Italian to the popedom, chose Urban VI.; but afterwards the leading members of the college retired to Fondi in Naples, and elected Clement VII., who set up his court at Avignon, while Urban remained at Rome. Clement was recognised as pope by France, Spain, Scotland, Sicily, and Cyprus, and Urban by the rest of Europe. This schism continued till the year 1417, when it was healed by the Council of Constance, which elected Martin V. to the papacy. (Mosheim's 'Ecclesiastical History,' cent. xiv., pt. ii., c. ii., sect. 15, &c.; Waddington's 'Church History,' c. xxiii.)

The other great schism is that between the Greek and Latin churches. [GREEK CHURCH.]

SCHISMA (from *σχίσμα, cleft, division*), an interval, used only in mathematico-musical calculations, equal to half a comma. [COMMA.]

SCHLIPPE'S SALT. The sulphantimoniate of sulphide of sodium. [ANTIMONY. *Pentasulphide of Antimony.*]

SCHOLIUM, *Σχόλιον* (Mathematics), a name given in the older mathematical writers to the remarks which follow a proposition. A scholium must be distinguished from a corollary, inasmuch as the latter necessarily contains some deduction from the demonstration which precedes, which is not the case with the former. A scholium is an appendix containing general remarks upon the scope of a proposition, its application, or its history: everything, in short, which is not an absolute corollary. The word is used by Cicero ('Ep. ad. Att.,' xvi. 7) in its general sense of remark, commentary, or explanation.

SCHOOLS. The true *Theory of Education* can only be developed by considering what the being is on whom it is designed to operate. Education is, according to its etymology, the leading out or unfolding of the human powers. It is obviously therefore a means for a certain purpose. To learn what that purpose is we must refer to experience, and we must investigate the capacities of the human being. These being ascertained, it follows that education is, in any particular case, an instrument for developing them. Now we know that man has not only physical and intellectual, but also moral and spiritual faculties, all of which education ought to take under its care. That education is incomplete which neglects any one of these faculties; and that education discharges its functions imperfectly which does not cultivate the faculties in such degree that their action may be well adjusted, and their general working be harmonious. But if there appear to be any one of the faculties apart from whose influence the rest work indifferently or produce baneful results, and which is found when in healthful vigour to strengthen, refine, and control the whole nature, this power ought to receive primary and chief attention. The work then of education is to foster, strengthen, and raise the physical, intellectual, moral, and spiritual capabilities of man. Some important deductions flow from these principles. Education ought to be universal both in relation to each individual and the community at large; for it ought to be co-extensive with the capabilities on which it is intended to act. It is contrary to the constitution of man and to the designs of God for any one of our capacities to remain undeveloped. They err who neglect to educate the body, and they also who neglect to educate the mind. These errors represent two different classes of men. A certain school of philosophy at least makes light of religious education; physical education has been lamentably neglected by the recognised teachers of religion. The latter error is now disappearing, but the former has been gaining ground; and this error is the more to be deplored because its consequences must be serious and lasting. If any one, certainly the religious faculty may be considered as the moving power of the human being. Religion indeed rightly understood is the central science, round which all other branches of knowledge and all other pure influences are grouped, towards which they gravitate, and from which they receive their light, their heat, and their highest value. But for the peculiar political circumstances of England, any system of popular education which omitted direct religious culture would probably have been considered by thinking men as defective.

There is in truth no other way than that which is afforded by a religious training for forming such a character as the trials and duties of life require both among the rich and the poor. The mere communication of knowledge, and even habits of reflection and inquiry, can do very little towards real happiness. What the people want is true wisdom and moral power, without which life is a scene of conflict and misery; but wisdom and moral power are the peculiar gifts of religion.

Morality therefore should be taught in the schools in connection with the sanctions of religion. Apart from religious influence morality may direct but cannot control. Morality may enlighten and it may enjoin, but of itself it is powerless to govern; it is preceptive, not impulsive, pointing out our path, but not urging us on to pursue it. Now it is power rather than knowledge that man wants; and all genuine power for moral purposes has its source in religion. It may be well to remember that these distinctions of morality and religion are factitious and arbitrary; they are not recognised in the records of the Christian revelation; they find no authority in the human mind. Religion includes morality, or rather, is morality as well as religion, comprising in itself whatever is necessary for man to know, do, and be, whether in this state or the next, in order to fulfil the divine will, to perfect his character, and work out his highest good. Consequently, he that is well trained in the knowledge and practice of the Christian religion has received both a moral and a religious education, and is fitly prepared for the duties of life.

From this it will be seen that the religious education here demanded is not of a dogmatical, much less a sectarian kind; but such instruction as may enlighten the mind of the child and the adult as to their capacities, their duties, and their hopes; and such a discipline as may work the instruction into the character till it "leaven the whole lump."

It is not a little curious that in regard to education we may take a lesson from the ancient Persians,* who, according to Xenophon, removing education from the hands of the parents into the hands of the state, gave the same attention to the moral training of the young as is now under the best circumstances given to their intellectual instruction, and so brought them up under the influence of precept and example, that the state was saved from the painful necessity of inflicting punishment, in consequence of having taken such preventive measures as relieved the youth from the desire of what is low and unjust. Morals with them were a practical science, the principles of which were first taught by word of mouth, and then by actual examples and by daily practice.

The morals taught in primary schools should have a regard to personal, domestic, and social duties, or the obligations which an individual owes to his family and to the state. The instruction should consist not of a mere dry detail of precepts, but should appeal to the reason and affections, that it may both develope them and gain such a reception in the breast of the scholar as to become the living power which governs his conduct.

The preceding remarks lead also to the conclusion that the culture which ensues from education is in itself an end, if indeed it is not the primary and great end of education. The husbandman sows the seed in order to produce grain; the educator disciplines the faculties that he may bring them into vigorous, healthful, and pleasurable activity. In both cases there is an adequate end, a result in which the agents may satisfactorily rest. Education can have no higher object than the creation of happiness by means of the formation of character. This is the great object of the Deity himself; and if even the power which education gives is regarded as an instrument, as a means to some outward result, still the pursuit of mental and moral culture as a good in itself, can have no other than a beneficial result. It is important therefore that the purposes for which education is sought should be placed and kept in their proper rank. That which is secondary must not, however good, be thrust into the first place; and above all that must not be altogether lost sight of, which in reality is in itself a most important result, if not the great end of education. The formation of character then, to make (so to speak) true men and women, beings with their faculties complete, and, in consequence, with all their internal sources of happiness, entire, full, and active—this should be an object carefully studied and diligently pursued by the educator. But here even superior minds halt behind the truth, making the chief object of education some extrinsic result—such as, in the case of males, fitness for the duties of their station in life; in the case of females, such as may prepare them to be pleasing wives and useful mothers—aims excellent in themselves, but scarcely entitled to hold the first rank, if for no other reason than this, that an outward accomplishment does not of necessity imply such an inward culture as will ensure health and vigour of character, and that durable and growing happiness which attends on genuine personal excellence.

The real nature of education considered as an instrument may also be gathered from these remarks. If the subject on which education operates is mental and moral in its character, and the effects which it labours to produce and the aims which it ought to pursue, also mental and moral, the instrument must be of a similar kind. Setting aside then so much of it as is designed for a physical result, education is a mental and a moral influence; in other words, it is mind acting on mind; it is a superior acting on an inferior character; it is human thought and human sympathies brought to bear on kindred elements in the bosoms of the young; it is the power of religion living and breathing in one soul, going forth into another, and kindling within that other corresponding vitality. Whence it is obvious that much of what is called education does not deserve the name; that a mechanical routine is not education, nor dexterity of hand, nor skill in shaping certain forms, nor the utterance of articulate sounds. If so, then reading, writing, and arithmetic, how well soever they may be taught, ought not to be dignified with the name, though they may in favourable circumstances contribute something to education.

The tenor of these observations has determined another thing, namely, what ought to be the prevailing spirit and what the discipline of a school. School in reality holds the place of home; home is God's school, but since present modes of life do not permit the parent to give his child a suitable training, he transfers education to the school. The school therefore should approximate as closely as possible to the home. Now in theory the homes of this land are Christian homes; the school in consequence should be a sort of Christian home. Such a union of terms calls up in the mind ideas of gentleness, forbearance, and affection. These then are the moral qualities which ought to prevail in the school. If so, severity and harshness must be banished as incompatible with the objects for which schools are instituted. Nor are they only incompatible, but they are actually preventive and subversive of those objects. The display of every moral quality produces its like in those who habitually witness it; and unless the aim in school-training is to produce a severe, harsh, and unloving character, severity and harshness must be studiously avoided.

So also the intellectual influence employed should be such as is likely to call out and strengthen the mental powers. The chief good of education is not to be looked for in outward results, nor even in the amount of knowledge communicated, but rather in such habits of mind,—power to fix the thoughts on any given object, to comprehend many particulars at one view, to resolve a complex subject into its component elements, to endure lengthened exertion, to carry determinations into practice, to find resources for thinking and for happiness within—as may fit a young person for discharging his duty under all circumstances. Mere instruction therefore is not education, but simply an instrument of education. The aim should be so to inform the mind, as by the very act of informing to develope and strengthen its powers. The instruction then that deadens the appetite for knowledge and overloads the powers is not education, but something foreign to its nature.

There are two modes, corresponding with two processes, by which the mind carries on its own education, namely, synthesis and analysis, which should be studied and employed by the educator as his great instruments. By synthesis he will, both orally and by means of manuals, offer knowledge to the mind in a simple, attractive, yet systematic form, rising by degrees from the more to the less easy, and from the simple to the complex. By analysis he will lead the child to decompose the matter of instruction which he has received, to trace out the relations of the several portions to one or more elementary principles, their connections with other branches of knowledge, and the more obvious deductions which may be made from them. Thus will he at once ascertain that he has succeeded in communicating his lessons to the pupil, and in making those lessons themselves prolific in additional information.

---

* Not that we suppose Xenophon represents a real state of society; but the opinions are just as valuable as if he did.

In the employment of these instruments the educator must be careful to follow nature in her order of unfolding the faculties; he must address those first which appear first, and he must carefully abstain from anything calculated to force any natural power into premature activity, or to overwork any faculty when it has come forth. Now the sight, the hearing, and the touch are the gifts of nature which are earliest developed. The power of reflection comes at a later period, and only as a result of the operation and influence of the senses. The mind of a child is an empty storehouse; the eye, the ear, and the touch are the portals through which this storehouse is supplied with matter, which, received and laid up, is afterwards operated upon by the mind, pursuant to its own laws. If then the senses are the first of our faculties which are fit for use, the senses should receive the earliest attention of the educator. A child can immediately observe; therefore the power of observation should be first cultivated. It is important that all the senses should receive cultivation, not merely for the information of which they may be made the vehicle, but also with a view to that training which is first among the purposes of education; but the eye may take some precedence, as the sense of sight comes first in the order of natural sensibility. At a very early period the educator should begin to teach his scholar how to use his eyes and other senses, both by words and by examples; and as the other faculties are found to expand themselves, so should they be from the first taken under his fostering care, that by exercise he may bring them to act harmoniously and efficiently.

It is, however, necessary that education should be also regarded as a means to some outward result, and here at once the social distinctions of life present themselves to our attention and modify our views. It is obvious that a child should learn that which will best prepare him for the labours, the trials, and the duties through which he will have to pass. In other words, the children of the poor ought to be taught what most concerns them to know, what they will have immediately to do, and what, other things remaining the same, will prove the most fruitful source of happiness. At the same time, the primary object of education—the formation of character—should also be kept in view; and the discipline through which a child ought to be conducted and the subjects of knowledge to be placed before him, must be determined by a joint reference to his capacities and his probable future station in life.

Now in treating of the mere external parts of education, health of the body is the first thing that demands our attention. The body is the instrument by which the mind executes its purposes, and by which therefore much of the good which education does makes itself felt. It would consequently seem to be of the first importance that this instrument should be kept in the highest state of efficiency. But this is an end which cannot be attained if men are brought up in total ignorance of the structure of their bodies, and of the laws of health. From the first, therefore, children should be habitually taught to know the conditions on which health depends; such as relate to the state of their dwellings, the condition of their persons as to cleanliness and other matters of the like kind, of which not only the labouring classes but many others are extremely ignorant. There is no peculiar difficulty in communicating the requisite knowledge, and on the part of the young the reception of it would be easy and pleasant. If we measure knowledge by its real usefulness, that is, its power to promote happiness, what comparison is there between this information and a knowledge of geography, history, or other things of the kind? A man may be ignorant of all these matters, and yet live a virtuous, happy, and long life, but he cannot with impunity remain ignorant of the laws of health. The most absurd and the most injurious prejudices prevail on this point among the people; and in general they imagine that sickness, disease, and death depend on causes altogether beyond their reach, on luck or chance, and that they have no other resource than passive submission.

It is also by means of the body that the children of the poor will have to get their bread. They should be taught to know this as a fact, as a simple piece of information, which involves neither merit nor demerit, neither honour nor dishonour. For such exercises of the body as they are likely to be called to, they ought from an early period to be prepared while at school by an industrial training.

This remark comprises much more than a demand of bodily labour from the young. It involves such a course of instruction as may best prepare them for their future occupations. There is no pursuit in life—not even that which is most mechanical—which does not depend on, or is not connected with, certain principles; for all manual labour is only the carrying out and realisation of results for which science has prepared the way. It is equally certain that there is no labour which may not be lightened or relieved by knowledge. A good education therefore would make the labourer acquainted with the facts and principles on which his art is built and thus enable him to enjoy the rational and sustaining pleasure of working understandingly, with a view to a given result, and labouring therefore in a manner fitted to improve his character as a man as well as his efficiency as a workman.

But no improvement can be expected in popular education until a better race of teachers is provided. Great as is the deficiency of schools, yet if they were filled with competent instructors, the chief evil would be remedied.

In the houses too of the working classes, particularly in the manufacturing districts, a change is most desirable. Whatever time may be occupied in school duties, there are many hours which a child spends during which the educator has no influence over him; and these are the very times at which the young are most susceptible of impressions; when the moral and intellectual capacities open to surrounding influences, and receive them readily and retain the impression deeply. In the actual state of things then, the real educators of the young are their parents, their brothers and sisters, their playmates, their casual companions—in one word, their home. No small part of these evils results from the employment of females in mills and factories. In the ordinary state of society all that should be peculiar in a female's education would be left to her mother. But among a large part of the manufacturing classes there are not mothers who could give anything approaching to the requisite education. There is then no other resource but the school. It is altogether impossible that the labouring classes, at least of the manufacturing districts, can ever be happy until a new and improved race of mothers appears. In addition, therefore, to the educational requisites already mentioned, it is necessary that there should be a sufficient number of girls' schools in which the ordinary arts of domestic life—baking, cooking, sewing, knitting, making and mending, should be taught. This matter is of vital interest to the working man, and therefore to the country, for it matters little what the labourer's earnings are, what his own intelligence is, if he has not a thrifty, kind-hearted, sensible, and industrious wife.

Among the changes desirable on the part of the parents is the existence of a disposition to provide out of their own resources suitable means for the education of their children. That it is their duty to make this provision when they have the power is unquestionable; and although it is too much to expect at the present, yet something may be done towards it, and the complete fulfilment of the claim may be looked to as an ultimate end. There is nothing but their own exertions which can bring to the labouring classes all the good which education can convey. The charity of education, like charity of every kind, tends to pauperise those whom it aims to benefit: and so long as the education of the poor depends on the efforts of rival and conflicting parties in religion or in politics, it is impossible that the power thus gained should not be used in order to further the opinions and interests of the several parties. In the meantime the people are regarded and treated as instruments for a purpose, and their education is shaped and varied not by a regard to what is absolutely best, but to what is conducive to the ends of the party which directs it. It is true that some good has resulted from the efforts of individuals and societies by which such education as the poor have received has been conducted during a century. It is equally true that these voluntary exertions have in many cases sprung from pure and enlarged benevolence. Still they could not under the circumstances fail to be accompanied by a large amount of sectarian and party feeling. At the present hour this is peculiarly the case. The church is arrayed against dissent, dissent is arrayed against the church, in competition for the largest share in the education of the children of the poor; and the rivalry is in greater or less activity through every city and village of the kingdom.

The magnitude of the evil and of the interests which are at stake seem to demand the intervention of the government by means of a general catholic and truly national education. But the conflict of parties gives little reason to expect this at present. Still the government is doing something; but the remedial measures employed cannot overtake the disorder. Perhaps after all, the end to be aimed at is, that the people should seriously take the education of their children into their own hands, or intrust it to proper persons of their own choice. This end may be facilitated by that love of independence which has hitherto been a marked feature in the character of Englishmen, who do not like either a government or individuals to be obtruding on their private concerns. Assuming, then, that the importance of education for all classes is now generally admitted, we proceed to notice our grammar and primary schools, and the laws which affect them.

Endowed Schools. An endowed school in England is a school which was established and is supported by funds given and appropriated to the perpetual use of such school, either by the sovereign or by private individuals. The endowment provides salaries for the master and usher, if there be one, and gratuitous instruction to pupils, either generally or the children of persons who live within certain defined limits. Endowed schools may be divided, with respect to the objects of the founder, into grammar-schools, and schools not grammar-schools. A grammar-school is generally defined to be a school in which the learned languages, the Latin and the Greek, are taught. Endowed schools may also be divided, with respect to their constitution for the purposes of government, into schools incorporated and schools not incorporated. Incorporated schools belong to the class of corporations called eleemosynary, which comprehends colleges and halls, and chartered hospitals or alms-houses. [COLLEGE.]

Endowed schools are comprehended under the general legal name of Charities, as that word is used in the act of the 43rd of Elizabeth, chap. 4, which is entitled "An Act to redress the Misemployment of Lands, Goods, and Stocks of Money heretofore given to Charitable Uses." Incorporated schools have generally been founded by the authority of letters patent from the crown, but in some cases by act of parliament. The usual course of proceeding has been for the person who intended to give property for the foundation of a school, to apply to the crown for a licence. The licence is given in the form of letters patent, which empower the person to found such a school, and to make, or to empower others to make, rules and regulations for its government, provided they are not at variance with the terms of the patent. The patent also incorporates certain persons and their successors, who are named or referred to in it, as the governors of the school. This was the form of foundation in the case of Harrow School, which was founded by John Lyon, in the 14th year of Elizabeth, pursuant to letters patent from the queen. Sometimes the master and usher are made members of the corporation, or the master only; and in the instance of Berkhampstead School, which was founded by act of parliament (2 & 3 Edw. VI., reciting certain letters patent of Henry VIII.), the corporation consists of the master and usher only, of whom the master is appointed by the crown, and the usher is appointed by the master. Lands and other property of such a school are vested in the corporation, whose duty it is to apply them, pursuant to the terms of the donation, in supporting the school. Many school endowments are of a mixed nature, the funds being appropriated both to the support of a free-school and for other charitable purposes. These other purposes are very various; but among them the union or connection of a hospital or alms-house with a free-school is one of the most common.

Where there is no charter of incorporation, which is the case in a great number of school endowments, the lands and other property of the school are vested in trustees, whose duties, as to the application of the funds, are the same as in the case of an incorporated school. It is necessary from time to time for the actual trustees to add to their numbers by such legal modes of conveyance as shall vest the school property in them and the new trustees jointly. These conveyances sometimes cause a considerable expense; and when they have been neglected, and the estates have consequently become vested in the heir-at-law of the surviving trustee, some difficulty is occasionally experienced in finding out the person in whom the school estates have thus become vested. When the school property consists of money, the same kind of difficulty arises; and money is also more liable to be lost than land.

Every charity, and schools amongst the rest, seems to be subject to visitation. We shall first speak of incorporated schools.

The founder may make the persons to whom he gives the school property on trust also the governors of his foundation for all purposes; and if he names no special visitor, it appears that such persons will be visitors as well as trustees. If he names a person as visitor, such person is called a special visitor; and it is a general rule that if the founder names no special visitor, and does not constitute the governors of his foundation the visitors, the heir-at-law of the founder will be visitor; and if there is no heir-at-law, the crown will visit by the lord keeper of the great seal. The king is visitor of all schools founded by himself or his ancestors. The duties of trustees and visitors are quite distinct, whether the same persons are trustees and visitors, or the trustees and visitors are different. It is the duty of trustees to preserve the school property, and to apply it to the purposes intended by the founder. In respect of their trust, trustees are subject to the jurisdiction of the Court of Chancery, like all other trustees; and of course they are answerable for all misapplication of the funds. It is the visitor's duty to inquire into the behaviour of the master and usher in their respective offices, and into the general conduct of the school. He must judge according to the founder's rules, which he cannot alter unless he is empowered by the terms of the donation to do so. There seems to be no reason for supposing that the king, in respect of royal foundations, has any further power than other persons, and consequently he cannot alter the terms of the donation, unless this power was originally reserved to the founder and his successors; but on this matter there may be some difference of opinion. The visitor, or those who have visitorial power, can alone remove a master or usher of an endowed school. The Court of Chancery never removes a master or usher, when they are part of the corporate body, on the general principle that this court has no power to remove a corporator of any kind; and when there is a visitor, or persons with visitorial power, the court never attempts directly to remove a master or usher, even if they are not members of the corporation. (17 Ves., Att.-Gen. *v.* the Earl of Clarendon.)

Trustees of endowed schools which are not incorporated are accountable in a court of equity for the management of the school property. But the internal management of the school still belongs to the special visitor, if there is one; and if there is no special visitor it belongs to the founder's heir. Trustees of endowed schools, simply as such, are merely the guardians of the property, as already observed; and it is their duty to take care of it, and to apply the income according to the founder's intention. It has, however, happened that in schools not incorporated the jurisdiction of the Court of Chancery and the visitorial jurisdiction have not been kept quite distinct; and cases have arisen in which it has been found difficult to determine what ought to be the proper mode of proceeding.

A free grammar-school was an endowment for teaching the learned languages, or Greek and Latin, and for no other purpose, unless the founder has prescribed other things to be taught besides grammar. This legal meaning of the term grammar-school has been fixed by various judicial decisions, and it appears to be established that, if the founder merely expresses his intention to found a grammar-school, the school must be a school for teaching Latin and Greek only, at least, so far as the teaching is gratuitous; other branches of instruction may be introduced, but the scholars must pay for this extra instruction.

Grammar-schools have now for a long time been solely regulated by the Court of Chancery, which, though affecting merely to deal with them in respect of the trusts and the application of the trust-monies, has in fact gone much farther. The court may be applied to for the purpose of establishing a school where funds have been given for the purpose, but the object cannot be effected without the aid of the court. It may also be applied to for the purpose of correcting a misapplication of the funds. The court may also be applied to in order to sanction the application of the school funds when they have increased beyond the amount required for the purposes indicated by the founder. Such surplus funds are often applied in establishing exhibitions or annual allowances to be paid to meritorious boys who have been educated at the school, during their residence at college. The master's scheme for the regulation of Tunbridge school, in Kent, which was confirmed by the Court of Chancery, established sixteen exhibitions of 100*l.* each, which are tenable at any college of Oxford or Cambridge, and payable out of the founder's endowment. It also extended the benefits of the school beyond the limits fixed by the founder, and made various other regulations for the improvement of the school, having regard to the then annual rents of the school estates.

The previous remarks on grammar-schools must be taken subject to the provisions contained in a recent Act of Parliament, which is the only attempt that has been made by the legislature to regulate schools of this class. This act (3 & 4 Vict. c. 77) is entitled "An Act for improving the Condition and extending the Benefits of Grammar-Schools." The act recites, among other things, that the "patrons, visitors, and governors of such grammar-schools are generally unable of their own authority to establish any other system of education than is expressly provided for by the foundation, and her majesty's courts of law and equity are frequently unable to give adequate relief, and in no case but at considerable expense." The act then declares that the courts of equity shall have power, as in the act provided, "to make such decrees or orders as to the said courts shall seem expedient, as well for extending the system of education to other useful branches of literature and science, in addition to or (subject to the provisions thereinafter contained) in lieu of the Greek and Latin languages, or such other instruction as may be required by the terms of the foundation or the then existing statutes, as also for extending or restricting the freedom or the right of admission to such school, by determining the number or the qualifications of boys who may thereafter be admissible thereto as free scholars or otherwise, and for settling the terms of admission to and continuance in the same, and to establish such schemes for the application of the revenues of any such schools as may in the opinion of the court be conducive to the rendering or maintaining such schools in the greatest degree efficient and useful, with due regard to the intentions of the respective founders and benefactors, and to declare at what period, and upon what event, such decrees or orders, or any directions contained therein, shall be brought into operation; and that such decrees and orders shall have force and effect, notwithstanding any provisions contained in the instruments of foundation, endowment, or benefaction, or in the then existing statutes;" but it is provided, that if there shall be any special visitor appointed by the founder or other competent authority, he shall be heard on the matters in question before the court makes any orders or decrees.

This enactment extends the power of the court over grammar-schools very considerably, as will appear from what has been said; not so much however, if we view what the court has done, as if we take the declarations of the most eminent equity judges as to what the court can do. The power however of changing a grammar-school into one not a grammar-school, which is given by this act, is a considerable extension of authority; but the power is limited to cases (§ 3) where the necessity of such a change arises from insufficiency of the revenues of a grammar-school for the purpose of such school. But this provision as it has properly been remarked, will be of very difficult application; for in many successful grammar-schools the revenue is small, and in some which are not successful it is large. Smallness of revenue, therefore, will not of itself prove "insufficiency of revenues" in the sense intended by the act. The same section contains also a provision, that except in this case of insufficient revenues, the court shall not by this act be authorised to dispense with any statute or provision now existing, so far as relates to the qualification of any schoolmaster or under-master. The dispensing power then which the court has often assumed, as shown in some instances above mentioned, remains as it was; that is, it does not exist at all.

When a grammar-school shall have been made into another kind of school under the provisions of this act, it is still to be considered a grammar-school, and subject to the jurisdiction of the ordinary as heretofore.

In case there shall be in any city, town, or place, any grammar-school or grammar-schools with insufficient revenues, they may be united, with the consent of the visitor, patron, and governor of every school to be affected thereby. The legal meaning of city and town (township) is sufficiently precise, but "place" has no legal meaning, and the framers of the act have forgotten to give it one in their 25th section, which treats of the construction of terms in that act.

The court is also empowered (§ 14) to enlarge the powers of those who have "authority by way of visitation or otherwise in respect of the disclipine of any grammar-school;" and where no authority by way of visitation is vested in any known person, the bishop of the diocese may apply to the Court of Chancery, stating the facts, and the court may, if it so think fit, give the bishop liberty to visit and regulate the said school in respect of the discipline, but not otherwise. This provision, for various reasons, will prove completely inoperative.

The act gives a summary remedy against masters who hold the premises of any grammar-school after dismissal, or after ceasing to be masters. Such masters are to be turned out in like manner as is provided in the case of other persons holding over, by the Act of the 1 & 2 Vict., entitled "An Act to facilitate the Recovery of Possession of Tenements after due Determination of the Tenancy."

All applications to the court under this act may be (not *must*) made by petition only, and such petitions are to be presented, heard, and determined according to the provisions of the 52 Geo. III. c. 101.

The act saves the rights of the ordinary. It is also declared not to extend "to the universities of Oxford or Cambridge, or to any college or hall within the same, or to the university of London, or to any colleges connected therewith, or to the university of Durham, or to the colleges of St. David's or St. Bees, or the grammar-schools of Westminster, Eton, Winchester, Harrow, Charter-House, Rugby, Merchant Tailors', St. Paul's, Christ's Hospital, Birmingham, Manchester, or Macclesfield, or Lowth, or such schools as form part of any cathedral or collegiate church." But the exemption does not extend to the grammar-schools of which the universities of Oxford or Cambridge, or the colleges and halls within the same, are trustees, though these schools were excepted from the Commissioners' inquiry by the 5 & 6 Wm. IV. c. 71.

It appears from the rules of many grammar-schools that religious instruction according to the principles of the Church of England, as established at the Reformation, is a part of the instruction which the founder contemplated; and when nothing is said about religious instruction, it is probable that it was always the practice to give such instruction in grammar-schools. That it was part of the discipline of such schools before the Reformation cannot be doubted, and there is no reason why it should have ceased to be so after the Reformation, as will presently appear. It is generally asserted that in every grammar-school religious instruction ought to be given, and according to the tenets of the Church of England; and that no person can undertake the office of schoolmaster in a grammar-school without the licence of the ordinary. This latter question was argued in the case of Rex *v.* the Archbishop of York. (6 'T. R.,' 490.) A mandamus was directed to the archbishop directing him to license R. W. to teach in the grammar-school at Skipton, in the county of York. The return of the archbishop was that the licensing of schoolmasters belongs to the archbishops and bishops of England; that R. W. had refused to be examined; and he relied as well on the ancient canon law as upon the canons confirmed in 1603 by James I. ('The Constitutions and Canons Ecclesiastical,' "Schoolmaster," 77, 78, 79.) The return was allowed; and consequently it was determined that the ordinary has power to license all schoolmasters, and not merely masters of grammar-schools. As to schoolmasters generally, the practice is discontinued, and probably it is not always observed in the case of masters of grammar-schools.

From the terms of this licence it appears that the master of every school who is licensed by the ordinary must be a member of the Church of England, and must take the oath and make the subscriptions and declarations which are recited in the licence.

It is a common notion that the master of a grammar-school must be a graduate of Oxford or Cambridge, and in holy orders, and such is the present practice; but it is by no means always the case that the rules of endowed schools require the master to be in holy orders. The founders seem generally to have considered this a matter of indifference; but many of them provided that if the master was in orders, or took orders, he should not at least encumber himself with the cure of souls. The principle clearly was, that the master of a grammar-school should devote himself solely to that work; and it was a good principle. The Court of Chancery has in various cases ordered that the master should be a clergyman, where the founder has not so ordered. Dean Colet, the founder of St. Paul's School, London, ordered by his statutes that neither of the masters of that school, if in orders, nor the chaplain, shall have any benefice with cure or service which may hinder the business of the school. He appointed a chaplain to the school, thereby appearing to intend that the religious instruction should not be given by the masters of grammar, who would be fully employed otherwise.

It has sometimes been doubted whether a master of a grammar-school could hold ecclesiastical preferment with it. If the founder has not forbidden this, there is no rule of law which prevents him. If the holding of the two offices should cause him to neglect the duties of either, the remedy is just the same as if he neglected either of his offices for any other cause.

Many grammar-schools are only free to the children of a particular parish, or of some particular parishes; but this privilege has occasionally been extended to a greater surface, as in the case of Tunbridge school. Some are free to all persons, which is the case with some of King Edward VI.'s endowments. Sometimes the number of free boys is limited, but the master is allowed to take pay scholars, either by usage or by the founder's rules. At present the practice is for masters of grammar-schools to take boarders if they choose, but in some cases the number is limited. Abuses undoubtedly have arisen from the practice of the master taking boarders, and the children of the parish or township for which the school was intended have been neglected or led to quit the school sometimes in consequence of the head master being solely intent on having a profitable boarding school. But in most cases the school has benefited by the master taking boarders; and this has frequently been the only means by which the school has been able to maintain itself as a grammar-school. When the situation has been a good one, an able master has often been found willing to take a grammar-school with a house, and a small salary attached to it, in the hope of making up a competent income by boarders. As this can only be effected by the master's care and diligence in teaching, a small neighbourhood has thus frequently enjoyed the advantage of its grammar-school, which otherwise would have been lost.

Endowments for education are probably nearly as old as endowments for the support of the church. Before the Reformation there were schools connected with many religious foundations, and there were also many private endowments for education. Perhaps one of the oldest schools of which anything is known is the school of Canterbury. Theodore, who was consecrated archbishop of Canterbury in 668 (according to some authorities), founded a school or college by licence from the pope. This school certainly existed for a long time; and there is a record of a suit before the Archbishop of Canterbury in 1321, between the rector of the grammar-schools of the city (supposed to be Theodore's school or its representative) and the rector of St. Martin's, who kept a school in right of the church. The object of the suit was to limit the rector of St. Martin's in the number of his scholars. This school probably existed till the Reformation, at least this is the time when the present King's school at Canterbury was established by Henry VIII., and probably on the ruins of the old school. Before the Reformation schools were also connected with chantries, and it was the duty of the priest to teach the children grammar and singing. There are still various indications of this connection between schools and religious foundations in the fact that some schools are still, or were till lately, kept in the church, or in a building which was part of it. There are many schools still in existence which were founded before the Reformation, but a very great number were founded immediately after that event, and one professed object of king Edward VI. in dissolving the chantries and other religious foundations then existing was for the purpose of establishing grammar-schools, as appears from the recital of the act for that purpose (1 Ed. VI. c. 14.) [CHANTRY.]

Though the act was much abused, the king did found a considerable number of schools, now commonly called King Edward's Schools, out of tithes that formerly belonged to religious houses or chantry lands; and many of these schools, owing to the improved value of their property, are now among the richest foundations of the kind in England. In these, as in many other grammar-schools, a certain number of persons were incorporated as trustees and governors, and provision was made for a master and usher. At that time the endowments varied in annual value from twenty to thirty and forty pounds per annum.

A large proportion of the grammar-schools were founded in the reigns of Edward VI. and Elizabeth, and there is no doubt that the desire to give complete ascendancy to the tenets of the Reformed Church was a motive which weighed strongly with many of the founders. Since the reign of Elizabeth we find grammar-schools occasionally established, but less frequently, while endowments for schools not grammar-schools have gradually increased so as to be much more numerous than the old schools. Foundations of the latter kind are still made by the bounty of individuals from time to time; and an Act of Parliament (2 & 3 Wm. IV. c. 115) has made it lawful to give money by will for the establishing of Roman Catholic schools. By the 23 Vict., c. 11, passed in 1860, the trustees of grammar-schools in England and Wales are empowered (except those mentioned in the 3 & 4 Vict., c. 77, those in connection with the National Society, those maintained by private subscription, and those where the endowment does not expressly demand conformity to certain religious doctrines) to frame orders for securing the admission of children whose parents are not in communion with the denomination or sect of which the doctrines are taught in the school. The statute of the 9th Geo. II. c. 36, commonly called the Mortmain Act, has placed certain restrictions on gifts by will for *charitable* purposes, which restrictions consequently extend to donations by will for the establishment or support of schools. [Mortmain.]

The history of our grammar-schools before the Reformation would be a large part of the history of education in England, for up to that time there were probably no other schools. From the time of the Reformation, and particularly till within the last half-century, the grammar-schools of England were the chief places of early instruction for all those who received a liberal training. From these often humble and unpretending edifices has issued a series of names illustrious in the annals of their country—a succession of men, often of obscure parentage and stinted means, who have justified the wisdom of the founders of grammar-schools in providing education for those who would otherwise have been without it, and thus securing to the state the services of the best of her children. Though circumstances are now greatly changed, there is nothing in the present condition of the country which renders it prudent to alter the foundation of these schools to any great extent; and certainly there is every reason for supporting them in all the integrity of their revenues, and for labouring to make them as efficient as their means will allow.

The voluminous Reports of the Commissioners appointed in 1818 and 1837 to inquire into Charities, contain the most complete accessible information on the several schools which were visited by the commissioners. But this vast mass of materials is only useful for those who wish to inquire into some particular endowment, or for the few who have leisure to study the Reports and the knowledge necessary to enable them to make a right use of them. The number of grammar-schools reported on by the commissioners is 700; the number of endowed schools not classical, 2150; and of charities for education not attached to endowed schools, 3390. The income of grammar-schools reported on was 152,047*l.* 14*s.* 1*d.*; of endowed schools (not classical), 141,385*l.* 2*s.* 6*d.*; and of the other charities given for or applied to education, 19,112*l.* 8*s.* 8*d.*

Primary Schools. The education supplied by primary schools may be considered as embracing not only that of young children, but that of the children of the poor in general. The consideration of it involves the whole matter of what is generally termed "popular education," comprising the Sunday-school, the Day-school, and the Infant-school.

The theory of the English church establishment supposes that the youth of the country are directly or indirectly under the care of the clergy for the purposes of education; and there was a period in which none but the clergy were engaged in the business of instruction. Various circumstances, however, added to the increase of population, its growth in wealth, the rise of new commercial interests, together with the spread of dissent, caused the people to outgrow the very scanty provision made for their education, so that towards the end of the last century an opinion became prevalent of the urgent necessity both for the extension and the improvement of the means for the education of poor children. The result was the commencement in England of a series of efforts which have led both here and abroad to the most beneficial results.

Raikes of Gloucester is generally considered the founder of Sunday-schools, but other persons preceded him in the benevolent effort to make the Sunday subservient to the education of neglected children. The Rev. Theophilus Lindsey, shortly after he had taken possession of his vicarage of Catterick in Yorkshire, in 1763, employed in this way a portion of each Sunday. Mrs Cappe, wife of the Rev. Newcome Cappe of York, then Miss Harrison, "endeavoured," she observes in her Life, "to imitate at Bedale the example which I so much admired at Catterick." In the year 1769 a Sunday-school was commenced by Miss Ball at High Wycombe, Bucks. She was a lady of great piety, and very earnest in doing good. Her custom was to assemble as many as thirty or forty children on Sunday morning, in order to hear them read the Scriptures and repeat the Catechism and the Collect preparatory to going to church.

The idea of Sunday instruction was communicated to Mr. Raikes by the Rev. Mr. Stock, curate of St. John's, Gloucester. [Raikes, in Biog. Div.]

The "National Schools" took their rise from the impulse given by the exertions of Dr. Andrew Bell. [Bell, Dr. Andrew, in Biog. Div.]

Joseph Lancaster, born in 1771, was a member of the Society of Friends. [Lancaster, Joseph, in Biog. Div.] His efforts resulted in the formation of the British and Foreign School Society.

Infant-schools are designed to prevent evil, and to train young children in the practice of virtue and kind feeling, as well as to the pursuit of knowledge, particularly in those cases in which the parents from their occupation are unable, or from their dispositions are unwilling, to take proper care of their offspring. At present having been found of great service in the humbler ranks of society, they are slowly extending themselves among the middle classes. If the whole of English education were planned with similar foresight and care, and conducted on similar principles, so as to make one connected series from infancy to manhood, extending through all ranks, modified only by the peculiar facilities and destination of each, the highest advantages would follow. The infant-school system makes the school-room into a nursery and a playground, in which virtue, intelligence, and love preside, direct the movements, and regulate and foster the emotions. The scholars are instructed while they play, and learn to associate pleasurable feelings with their school pursuits.

The real founder of Infant-Schools appears to have been the Pastor Oberlin [Oberlin, in Biog. Div.]; but Pestalozzi [Biog. Div.] also aided. Mr. Owen was the first Englishman to establish an infant-school on a large scale, and for definite purposes—and certainly the school which he founded at New Lanark in Scotland at least ranks among the earliest.

In the year 1819 Henry Brougham, the Marquis of Lansdowne, Joseph Wilson, John Smith (who had seen the schools at New Lanark five years previously), and other gentlemen, established, by subscription among themselves, a school in Brewer's Green (now Vincent Square), Tothill Fields, Westminster, on the plan of Mr. Owen's schools at New Lanark; and James Buchanan, an experienced teacher in those schools, came to London, with Mr. Owen's approbation, to superintend the new school.

On the 24th of July, 1820, an infant school was opened in Quaker-Street, Spitalfields, London. This school was established at the sole expense of Joseph Wilson, above mentioned. Samuel Wilderspin and his wife were engaged to manage the school, and their salaries were fixed and paid by Mr. Wilson. Wilderspin had been previously a clerk in a mercantile house in the city. He remained in this situation some years, and published a small work 'On the Importance of educating the Infant Poor from the age of eighteen months to seven years, containing an account of the Spitalfields Infant School, and the new System of Instruction there adopted. By S. Wilderspin, master of the above school. 12mo, 2nd edition, with considerable additions, Lond., 1824.' The first edition was probably published in 1823, but we have no evidence. Mr. Wilderspin was afterwards employed in delivering lectures on infant education, in assisting in the establishment of new schools, and in otherwise promoting the cause of infant education in all parts of Great Britain as well as in London. Mr. Buchanan was master of the Westminster infant school about twenty years, and then went to America.

Of a different class in many respects to either of those yet noticed are the schools called *Birkbeck Schools.* They were established by a private gentleman, Mr. William Ellis [Ellis, William, in Biog. Div.], at his own expense, but are intended to be ultimately maintained by the weekly payments of the children. As is more fully explained in the article referred to (see also the 'Companion to the Almanac,' for 1860, p. 13, &c.), the distinctive feature of the schools is that instruction in *social science* is made a matter of primary importance: it being the opinion of the founder "that the habits of reflection and self-examination, which its study calls forth, cannot fail to impart a useful bias to the character and conduct in after life." Several of these schools are in operation, the principal one, a large and flourishing establishment in which several hundred children are under instruction, is at Peckham.

Reformatory and Ragged Schools have been treated of under those heads.

A "College of Preceptors" has been also established, which examines and gives certificates of competence to persons intending to be teachers. This has tended greatly to improve the teaching in private schools; while the Oxford and Cambridge middle-class examinations of the scholars of any school, as well as the throwing open, to a certain extent, of government situations to public competition, have had considerable influence in raising the character of the instruction given.

Training-schools have also been established in connection with the National Society. Some of the Diocesan Boards of Education appropriate a part of their funds to the erection of school-houses; others assist in increasing the salaries of teachers and improving the routine of schools.

In giving a brief notice of what has been done for the improvement of education in England, the efforts of government claim chief attention. Those efforts have proceeded on the principle of stimulating and expanding the agencies which are already in existence, rather than of supplying the means for establishing a general and uniform system of education, under the control of the state. For several years grants of 20,000*l.* per annum were made by Parliament, and distributed chiefly through the National and the British or Lancasterian schools, in furtherance of education.

These schools increased, and with them the government grants. Schools receiving grants are subject to the inspection of persons appointed by government. In 1859 there was granted by Parliament 836,920*l.* for public education in Great Britain, and 249,468*l.* for Ireland; and in England, in 1858, at the time of inspection there were 821,744 scholars present. In 1860 the grants were 798,167*l.* for Great Britain and 270,722*l.* for Ireland; and in Ireland, on Dec. 31, 1859, there were 519,175 children on the rolls, and an average of 269,203 in daily attendance. Grants are allowed by the Council of Education to all schools admitting of the inspection of the government inspectors. There are 24 training colleges. In almost every Poor-Law Union schools are established for the pauper children, at which, in July, 1859, there were 65,656 children receiving instruction. In Ireland, agricultural schools have been established in connection with the Poor-Law Union, which have proved successful in their pecuniary results and beneficial to the children.

The efforts of the legislature have not been confined to grants of money or to the poor. Without noticing the number of schemes proposed, and the debates upon them, in which the adherents of the voluntary principle, and those advocating a national superintendence and support, have contrived to neutralise each other's efforts, we will shortly notice what has been actually done. In 1842 an act was passed for facilitating the acquisition of sites for school-houses, which was repeated, amended, and extended in 1850, 1852, and 1853. In 1843 land and buildings occupied by societies for literary and scientific purposes were exempted from the payment of county, borough, parochial, and other local rates; and in 1854 further facilities for the institution of such societies were afforded by another act. In 1844, in a Poor-Law Amendment Act, the Poor-Law Commissioners were empowered to combine parishes and unions into school districts, to form boards for their governance, which boards, subject to the regulations of the commissioners, were to appoint, pay, and control its teachers and other officers for the purpose of instructing the children of the poor; but no child was to be compelled to attend any religious service contrary to the principles of, or be instructed in, any religious creed contrary to that professed by. the parents; and in 1848 the provisions of the act were amended, by extending them to parishes not in unions, and removing the limitation of expense, previously limited to one-fifth of the aggregate of the poor-law expenditure. The 18 Vict. c. 34, 1855, gives guardians of poor-law unions power to afford relief, so as to enable poor children, between the ages of four and sixteen, to be sent to schools. In 1847 the law regulating the attendance at school of children employed in print-works was amended. In 1850 an act was passed empowering town-councils to establish public libraries and museums, by imposing a small rate, such libraries and museums to be open to the public free of expense; extended in 1855 to places not having councils and to parishes; and similar acts were passed for Scotland and Ireland in 1853, 1854, and 1855.

In addition to this legislative action, the general public have not been wanting in efforts to diffuse education. In most of the large towns ragged schools have been formed and supported for the instruction of the more destitute children; and, in conjunction with mere school learning, it has been endeavoured to inculcate habits of industry, by establishing shoe-black brigades and crossing sweepers, by which boys during the day are enabled to earn money, a part being devoted to their support, and the remainder placed to their account, to form a fund for their future advancement, their evenings being spent in school. The results, on the whole, have been very satisfactory. Schools have also been established for teaching girls common things, chiefly in domestic economy. The preparation of teachers has been also more attended to, and few of the paid instructors, either male or female, are now appointed to any of the schools without certificates of capability from recognised examiners. For this purpose the National Society, the British and Foreign School Society, the Congregational Board of Education, and the Voluntary School Society, have established normal and model schools, where instruction is afforded, capability tested, and certificates granted. Inspectors are appointed to visit all the schools by the Board of Education, and also by the above-named societies to visit their own.

In 1845 an act was passed for endowing Maynooth College for the better education of the Roman Catholic priesthood. In the same year was also passed an act "enabling her Majesty to endow new Colleges," in consequence of which the Queen's Colleges of Belfast, Cork, and Galway have been built and endowed. A sum of 100,000*l.* was assigned out of the Consolidated Fund for purchasing the sites, and erecting and furnishing the buildings of the three Colleges. Her Majesty and her successors were made visitors, with power to appoint, by sign manual, persons to execute the office. The appointment of the presidents, vice-presidents, and professors, was entrusted to the Crown, until parliament should otherwise determine. The Commissioners of the Treasury were empowered to issue annually a sum not exceeding 7000*l.* for the payment of salaries and other expenses in each college; it being moreover provided that reasonable fees should be exigible from the students. Lecture-rooms were directed to be assigned for religious instruction: and it was enacted that no student should be allowed to attend any of the colleges unless he should reside with his parent or guardian, or some near relation, or with a tutor or master of a boarding-house licensed by the president, or in a hall founded and endowed for the reception of students.

A president and vice-president for each college were soon after nominated, and the erection of the buildings was begun. The other appointments were made in August 1849, and the three colleges were opened in the end of October following. An additional sum of 12,000*l.* had shortly before been granted by Parliament for providing them with libraries, philosophical instruments, and some other requisites.

The peculiarity of and the need for such colleges arose from the state of religious feeling in Ireland. The greatest proportion of the people are Roman Catholics, and there is a large number of Presbyterians; but in Trinity College, Dublin, there are no arrangements which even recognise the existence of any form of religious belief but that of the Established Church; not only is the student who may hold any other creed (in so far as such dissenting students are admitted at all) left without any spiritual superintendence whatever, but the entire system of teaching and discipline is in the hands of members of the Church established by law, and is regulated and administered in all respects in conformity with the doctrines and ritual of that Church. Notwithstanding considerable opposition the experiment has succeeded. The colleges are attended by students of all religious creeds; but while thus free to all, the morals and the peculiar faith of the student are sedulously attended to.

Neither in England have the efforts to promote education been confined to the poor. At Durham the bishop and dean and chapter obtained an act of Parliament in 1832, authorising the institution and endowment of a university, which was opened for students in October 1833. In 1837 a royal charter of incorporation was obtained by which the style and title of "the Warden, Masters, and Scholars of the University of Durham" was given to the institution. The charter gave the power of conferring degrees, and confirmed the rights and privileges assured to it by act of Parliament, usually enjoyed by chartered universities. The bishop is appointed visitor; the dean of Durham is constituted warden. To the professorships of divinity and ecclesiastical history and of Greek and classical literature, which are both in the patronage of the bishop, canonries in the cathedral are annexed. The professor of mathematics and astronomy, the readers in law, Hebrew, history and polite literature, and natural philosophy, the lecturer on chemistry and mineralogy, and other officers of the university, are appointed by the dean and chapter. Of University College the warden of the university is master. Bishop Hatfield's Hall, instituted in 1846, is for divinity students. It has four tutors, one of whom is principal, a censor, and a chaplain. The academical year consists of three terms of not less than eight weeks each, which are called Michaelmas, Epiphany, and Easter Terms. The age of admission to the academical course is from 16 to 21; and for the divinity course, between 21 and 26; beyond this age students must be admitted by special leave. Care has been taken that the necessary expenses of students shall be as moderate as is consistent with comfort, and any approach to extravagance is sedulously guarded against.

In 1854 an act of Parliament extended the right enjoyed by the graduates of Oxford and Cambridge to practise physic without farther examination, to the graduates in medicine of the University of London. In the same year by another act, a commission was appointed to draw up regulations for the improvement of Oxford University, and in 1857 a similar one was passed for Cambridge. Under these commissions many valuable improvements have been effected, and more may be confidently expected. Among those effected are the breaking up of the close scholarships (especially those of Winchester school), and throwing them open to general competition; the dispensation from the taking of a number of unnecessary oaths; the establishment of private halls; and the abolishing of the oath on matriculation and on taking the degree of B.A.; by which last regulation Dissenters are admitted to the whole advantages of a university education. In Scotland also an agitation is being made for some improvement in the universities.

SCHOONER. [Ship.]

SCHWEINFURTH GREEN. [Copper.]

SCIATICA is a name often applied to all rheumatic affections about the hip-joint and the back of the thigh, but which is more properly adapted to a disease of the sciatic nerve, either inflammatory, or similar in its nature to those which in other parts are designated Neuralgia, or Tic doloureux. The pain in sciatica commonly follows, or is situated in some part of, the course of the sciatic nerve, extending from the inner portion of the buttock along the back of the thigh to the ham, and is sometimes continued to the foot along the track of the nerves of the leg. It occurs specially in adults and in old persons, and more particularly in those that have been subject to rheumatism; the pain is generally remittent, and seldom ceases altogether; but is commonly aggravated in the evening. For the treatment and other circumstances connected with sciatica, we must refer to the articles Neuralgia and Rheumatism.

SCIENCE. The word *scientia*, in real Latin, simply means knowledge, and we must attribute the subsequent application of the word to particular kinds of knowledge, to causes similar to those which have influenced the use of the equally general term Mathematics. It does not appear that in the earlier parts of the middle ages *science* had any distinct meaning as opposed either to *literature* or to *art*. Almost at the earliest establishment of universities, the great preliminary branches of knowledge were separated from the rest under the name of *liberal arts*; that is to say, the Trivium, containing grammar, logic, and rhetoric; and the Quadrivium, containing arithmetic, geometry, astronomy, and music. If theology, law, and medicine were called sciences, it was not in any distinctive sense, and we are inclined to think that *scientia* must then have been rather a term subaltern to art, than opposed to it. We find Roger Bacon ('Op. Maj.,' cap. xv.) speaking of the nine mathematical sciences, and the six great natural sciences, which contain under them many other sciences: and his contemporary Robert of Lincoln ('Tract. de Art. Lib.'), after laying it down that the arts (not sciences), of which it is the office "operationes humanas corrigendo ad perfectionem ducere," are seven in number, proceeds to describe them without a single use of the word science. How the word grew it is not our business to inquire closely; but by the middle of the 16th century the word *science* had begun to appear as denoting connected and demonstrated knowledge, in opposition to *art*, which signified digested rules of operation not connected with each other by deduction from common first principles. Thus Tartaglia, a writer on algebra (which was then, and most properly, called only an *art; ars magna*, or arte maggiore), styles Euclid, in the preface to his edition of the Elements, "the sole guide to the mathematical *sciences*." By the middle of the 17th century, the term science was freely used in the sense which it has never since lost, namely, that in which it is opposed to literature. But the old distinction of science as opposed to art has still remained, though the two terms, in this sense, have been in great measure superseded by theory and practice; but improperly, for the distinction between science and art is one thing, and that between theory and practice another. [THEORY.]

A science, as distinguished from an art, is a body of truths, the common first principles of which are supposed to be known and separated, so that the individual truths, even though some or all may be clear in themselves, have a guarantee that they could have been discovered and known, either with certainty or with such probability as the subject admits of, by other means than their own evidence. It is not necessary that these truths should have been discovered by a scientific process; it is enough that they admit of such treatment subsequently. The telescope, for instance, may have been discovered accidentally; but it can now be demonstrated beforehand that such an instrument must produce the effect which it is known to produce, and the rules for its construction may be deduced from the simple fundamental properties of light. In the sense of the word above used, the number of perfect sciences is not so great as is commonly supposed; for many branches of knowledge which bear the name are not perfect sciences, such as medicine, zoology, and geology; in all of these, large classifications have been made, many principles have been deduced which seem to be of universal application, and much has been done to make these known principles point out the direction of inquiry; but it would be idle to say that either of them is a science in the sense in which astronomy is a science.

Science, as opposed to literature, means any branch of knowledge in which the affections of mind or matter are to be made the subject of reasoning, with a view to discover and apply first principles. The distinctions of mental and physical sciences, the subdivision of the former into ethical and psychological, &c., whatever terms may be employed, are real and useful. But as it is not the object here to classify human knowledge, but only to give a slight account of the mode of using a word, we may pass on to its common signification.

By science, in popular language, is meant simply mathematical, physical, or natural science, not with reference to principles, but to results. Calculation, collection of natural objects, construction of models, use of philosophical instruments, any or either, is science, or part of science; and a man of science (man of *a* science, or man of the art which is built upon *a* science, would frequently be a correct description) may be either a mathematician, mechanist, engineer, medical practitioner, astronomer, geologist, electrician, zoologist, ornithologist, &c. To this sort of designation there can be no objection in itself, and it is convenient as distinguishing followers of science, or of a science, from those of literature. But it is not sufficiently precise in itself to distinguish the followers of different sciences from one another. When a literary man is named, his pursuit is generally indicated; the historian, the antiquary, the poet, the novelist, the politician, the scholar, and the linguist, are not confounded by means of a general term: insomuch that "literary man," by itself, generally implies one of information, but not of distinguished depth in any one particular branch. But the inquirer into the sciences of electricity and magnetism, for example, has no name to distinguish him from the observer and classifier of insects; that is to say, the proper technical names are not familiar to the world at large. But this is the least inconvenience. When the word science comes to be used in its high and proper sense, indicative of truth discovered, error prevented, inquiry organised, judicious habits formed, and mental energy strengthened, it must be difficult for those who are used to the common sense of the word to imagine the truth of many things which are said about it. "All we require is, that he will hold his former opinions and judgments without bigotry, retain till he shall see reason to question them, be ready to resign them when fairly proved untenable, and to doubt them when the weight of probability is shown to lie against them. If he refuse this, he is *incapable of science*." Now this, though the word of a good authority, and perfectly true, is nevertheless notoriously false in the common sense of the word science: a man may be incapable of the preceding state of mind, and may be a *man of science*. There is no remedy for this confusion of terms, except that which every one must make for himself, by attention to the different senses of the word, the higher and the lower.

SCIENCE AND ART, DEPARTMENT OF. This department of the Committee of Privy Council on Education owes its origin to the suggestions contained in the Second Report of the Commissioners for the Exhibition of 1851. After urging the necessity of the industrial classes of this country receiving more systematic instruction in science and art in order to enable them to maintain their pre-eminence in the neutral markets of the world, the Commissioners impressed on the government the advantages which would result from bringing the various institutions connected with Science and Art that were supported by the public funds, into close connection with each other, instead of their remaining under different departments of the government. The government took a favourable view of the suggestion; and, as a part of the "comprehensive scheme for the advancement of the fine arts and of practical science," announced from the throne at the opening of the session of 1852-53, the Lords of the Treasury, in March, 1853, gave their formal concurrence to the proposed arrangement of the Privy Council to "unite in one department, under the Board of Trade, with the Departments of Practical Art and Science, the kindred and analogous institutions of the Government School of Mines and Science, the Museum of Practical Geology, the Geological Survey, the Museum Irish Industry, and the Royal Dublin Society, all of which are in part supported by parliamentary grants;" and, the Treasury minute proceeds, "my Lords have given directions that the estimates for all these institutions shall be brought together under the general head of 'Board of Trade Department of Science and Art.'" The immediate purpose of this amalgamation, it was declared, was to bring the whole of these institutions under one common superintendence, to establish a Central Metropolitan School of Practical Science as well as of Art, and to encourage and extend the formation of minor local institutions which should be in connection with, and assisted by, the central institutions, but as far as possible self-supporting and under the management of the local authorities.

As was said above, the institutions thus brought together under one department, were all in part supported by parliamentary grants. The sums voted for each in the year previous to the amalgamation were: Government School of Mines and Science, 800*l.*; Museum of Practical Geology, 5272*l.*; Geological Survey, 5500*l.*; Museum of Irish Industry, 3348*l.*; Royal Dublin Society, 6340*l.*; Department of Practical Art, including the provincial Schools of Design, 17,920*l.*; in all, 39,181*l.*: but the sum actually granted was 41,586*l.*; additions having been sanctioned of 150*l.* to the School of Mines, and 2255*l.* to the Department of Practical Art.

Of these institutions the character may be briefly indicated. The Government School of Mines and of Science applied to the Arts was founded in 1851, in consequence of memorials addressed to government by the mining districts of the United Kingdom, in which it was shown that the schools for the instruction of persons engaged in mining pursuits by various Continental governments had much increased the economy, efficiency, and safety of mining operations in the countries in which they had been established, and that the want of similar schools had long been felt in the mining districts of this kingdom. The Government School of Mines was accordingly opened in connection with the Museum of Practical Geology in 1851. It is now merged in the Metropolitan School of Science applied to Mining and the Arts, which forms one of the two great branches of the department which is the subject of this article. The Museum of Practical Geology, which will be noticed more fully presently, was in 1850 removed to the building erected for its reception in Jermyn Street, St. James's. Ever since the establishment of the Museum, the Geological Survey of the United Kingdom has been carried on in connection with it. To these institutions we may add the Royal College of Chemistry, founded in 1845, it having been, in 1853, transferred to the Department of Science and Art.

The Department of Practical Art was a development, or rather reconstitution, of the central Schools of Design, originally founded in 1837, in accordance with the recommendations of a committee of the House of Commons. The Department of Practical Art was created but a short time before its amalgamation with the other institutions in the Department of Science and Art, and before it had come into full operation as a separate institution.

The Royal Dublin Society for the improvement of husbandry, manufactures, and other useful arts and sciences, was founded in 1731, and incorporated by royal charter in 1749. It possesses a valuable museum of natural history; an agricultural museum; an excellent library; a museum of sculpture, casts, &c. From its establishment, we believe, it has had its schools of painting, sculpture, and the fine arts, from which many of the best native artists have proceeded. It has also a good chemical laboratory; and a convenient theatre for the delivery of lectures. The Botanic Gardens at Glasnevin belong to the Society, and the Zoological Gardens, Phœnix Park, are in connection with it. Though amalgamated with the Department of Science and Art, the Society is conducted wholly by its own council, the duties of the department being confined to supervision and suggestion.

The Museum of Irish Industry was established by the government in 1845, and placed under the direction of Sir Robert Kane, so honourably distinguished for investigations in connection with the industrial pursuits of Ireland. In object, the Museum of Irish Industry resembles pretty closely the London Museum of Practical Geology, but takes a somewhat wider and more diversified range. It has a staff of professors who lecture in the theatre of the Royal Dublin Society; the professors, since the union with the Department of Science and Art, being common to the two institutions. The system of lectures, which has some peculiarities, is an extension of that previously adopted by the Royal Dublin Society. Short courses are given during the day, chiefly to the upper classes; and other courses are given in the evenings, chiefly to the sons and assistants of persons engaged in trade, and to artisans. Examinations take place at the end of every course, when prizes are awarded to the more successful students, and a general competitive examination is held at the end of every year. In addition to this, lecturers on science are sent to the provincial towns, and local examinations take place at stated periods in connection with their instruction.

The institutions which were united to form the Department of Science and Art, it will have been noticed, all belonged to England and Ireland. But in 1854 the necessary steps were taken for the formation of an Industrial Museum for Scotland, similar to those of London and Dublin. A site was purchased by the government near the University of Edinburgh for the building; and the museum belonging to the town-council, and the valuable collection of models, minerals, &c., of the Highland Society were transferred to the Crown, and thus an excellent basis was obtained for the proposed museum. The museum was placed under the direction of Dr. George Wilson, through whose zealous exertions singularly rapid progress was made in forming the collections, which at his death, in November, 1859, already numbered upwards of 10,300 specimens. A Museum of Natural History, Edinburgh, has also been formed in connection with the Department of Science and Art. A building is now in course of erection which is intended to contain both these museums.

Originally the Department of Science and Art was constituted a section of the Board of Trade, but in February, 1856, it was, by an order in council, transferred to the Committee of Privy Council on Education. Of that committee it now forms a distinct division: its functions having reference to the secondary instruction of all classes of the community in those principles of art and science which conduce to the industrial interests of the country, while the functions of the other division of the Committee of Education refer to the primary instruction of the young; the two divisions being kept entirely unconnected. The Department itself consists of two sections—a School of Science, with its connected museums and affiliated institutions, having its head-quarters at Jermyn Street; and a School of Art, with its various collections and associated schools, having its head-quarters at South Kensington, where also are the offices of the Department. The sum voted for the Department of Science and Art in 1860 was 94,951*l.*, being an increase of 11,709*l.* over the previous year, and more than double the sum voted for the several institutions prior to their consolidation.

It remains to notice shortly the present position of the two sections of the Department. The Metropolitan School of Science, applied to mining and the arts, has, in the words of the official prospectus, "for its chief object and distinctive character (to which everything else is subsidiary), to give a practical direction to the course of scientific study." And the course of instruction which is imparted to the student, while it does not profess to qualify him to undertake the direction of mining or other technical operations, is intended in combination with future training, to "render him in the highest degree competent, not only to engage in any special branch of industry, but to promote its further development." The institution is under the general supervision of a director, Sir R. I. Murchison, the eminent geologist, who succeeded the late Sir H. T. de la Beche, and the instruction is given by professors of chemistry, natural history, applied to geology, physical science, applied to mechanics and mechanical drawing, metallurgy, geology, and mining and mineralogy, each men of the highest standing in their respective departments. The mode of instruction is by lectures, by written and oral examinations, by practical teaching in the laboratories and drawing office, and by field surveying and geological and natural history excursions. The field of study is separated into—a general division, for those who desire a general knowledge of science; a mining and metallurgical division; a technical division, for those who propose to engage in arts or manufactures depending chiefly either on chemical or on mechanical principles. For each of these divisions the course of study extends over two years, of three terms in each. Students must be at least 16 years of age on admission. Several exhibitions have been founded, to be competed for by matriculated students. The lectures are open to occasional or non-matriculated students, on payment of a somewhat higher fee; and special short courses of evening lectures, at an extremely low fee, are given every session to working men only, and are attended always by as large a number (600) of diligent students of that class as the theatre will accommodate.

The Metropolitan School of Science enjoys rare advantages from the ready access which the students have to the treasures accumulated in the museum at Jermyn Street. These consist of the extensive and admirably arranged collections formed during the progress of the geological survey of the United Kingdom, "illustrative of the structure of the British islands, and of the applications of geology to the useful purposes of life," under the able directors and indefatigable staff of the survey. To these have been added a numerous selection of models of mines, mining tools, and working models of mining machinery; of tools, and models, and specimens of machinery for general purposes; of historical specimens of manufactures in glass, earthenware, and the metals; and of foreign and colonial mineral productions. Many of the specimens are of great rarity and beauty, but their main interest lies in their technical or scientific value, and the whole are carefully classified and conveniently arranged. The museum is open gratuitously to the public during five days of the week. In 1859 it was visited by 25,309 persons.

The maps and sections of the geological survey, and a large collection of plans and sections of mines, &c., belonging to the Mining Record Office, are deposited in the building in Jermyn Street. The chemical laboratories are those of the Royal College of Chemistry in Oxford Street, which, as already mentioned, became in 1854 the property of the Government.

In connection with the Metropolitan School of Science, special schools of science, or classes for instruction in science, have been established since 1853 in several of the large manufacturing, mining, and pottery towns. These schools, in accordance with the principle laid down by the government on the formation of the Department of Science and Art, are in a great measure self-supporting, the Department exercising a certain amount of control, and, in return, affording a limited pecuniary aid to certified masters of the schools. Certificates are also granted by the Science Inspectors to any teachers who pass a satisfactory examination in—1, practical and descriptive geometry, with mechanical and machine drawing; 2, physics, mechanical and experimental; 3, chemistry; 4, geology; 5, natural history: and those who are successful "receive certificate allowances of 20*l.*, 15*l.*, or 10*l.*, in each, while engaged in teaching."

Navigation Schools have also been established in connection with the Department. They are intended to afford instruction to officers of the mercantile marine on the subjects of their examination for certificates of the Board of Trade, and similar instruction to youth about to enter on a seafaring life. Besides three in London, Navigation Schools have been opened in nine of the principal outports, and they seem on the whole to have met with a fair amount of success. In 1859 there were 2490 students in the Navigation Schools.

The Art Schools are of older date than the Schools of Science, and, appealing to a wider circle, have almost necessarily made greater numerical progress. The Art branch of the Department has, as we have already said, its head-quarters at South Kensington, on the estate purchased by the Commissioners of the Exhibition of 1851, and is a development or reorganisation of the old Schools of Design. As at present organised, the special objects of the Art section of the Department are in the words of the official programme—"1. To train male and female teachers to give instruction in Art, to certify them when qualified, and to make them annual fixed payments, varying according to their acquirements. 2. To aid and assist committees in the provinces desirous of establishing Schools of Art. 3. To hold public inspections and examinations, and to award medals and prizes to the most deserving candidates. 4. To collect together works of art, pictures, &c., in the central Museum, and books and engravings in the central Library. 5. To circulate among the Schools of Art objects from the Museum, and books and engravings from the Library."

The buildings at South Kensington include the offices of the Department, the Training School for Masters and Mistresses, the Normal Central School of Art, the Art Library, and the Museum.

"The Training School has for its special object the education of Art-teachers, male and female, but it also aids in supplying certificated Art-masters or mistresses to teach drawing to schools in connection with the Committee of Council on Education. The course of studies embraces, besides all the ordinary branches of Art-Education, instruction in various direct applications of Art-power to mechanical and manufacturing industry. It comprehends the following subjects:—Free-hand, architectural, and mechanical drawing; practical geometry and perspective; painting in oil, tempera, and water-colours; and modelling, moulding, and casting. These classes include architectural and other ornaments, flowers, landscape, objects of still-life, &c., the figure from the antique and the life, and the study of anatomy as applicable to Art; and some technical studies, such as enamel painting, and drawing and engraving on wood. The students have full access to the Museum and Library, either for consultation or copying, as well as to all the public lectures of the Department. Special classes are arranged in order to qualify schoolmasters and schoolmistresses of parochial and other schools to teach elementary drawing as a part of general education."

In connection with the Central School of Art there are nine Metropolitan District Schools, and one school for female students only. The provincial Schools of Art have increased greatly in number since the formation of the Department. These schools are, like the Schools of Science, in the main self-supporting, but the Department assists in paying the certified teachers, and in various ways aids in providing the school materials, and in rendering assistance to the institution. They are now in all eighty-six in number; and at the last return they were the means of affording instruction in drawing and painting to above 84,000 students—but this number includes, besides students in the art schools, pupils in training colleges, and children in various classes of primary schools "under instruction in drawing," who can hardly in fairness be ranked as Art-students. The Department, in fact, now, besides the training which it affords in its central and metropolitan schools, and the special Provincial Schools of Art in connection with it, proffers the services of a certified teacher in drawing to any school or schools, furnishing an aggregate of 500 children for instruction in drawing; and it further offers the aid to such schools of examinations and prizes, at stated periods.

The Museum of the Department at South Kensington will be noticed under SOUTH KENSINGTON MUSEUM.

SCILLA, or as Steinheil, who separates it and another species (S. Pancratio) from the old genus, terms it, Squilla Maritima, also Urginea Scilla (Steinh.), or Sea-onion, is a plant common on the sandy shores of the Mediterranean, Portugal, the Levant, and in North Russia. It is imported into Britain from Malta and other parts of the Mediterranean, and also from Petersburg and Copenhagen. The officinal part is the bulb, of which there are two varieties: the one large and whitish externally; the other smaller, of a brownish-red colour. The former is preferred in England, the latter in Germany. This appears to be the Squilla Pancration of Steinheil. The bulb part partakes in its outer part of the nature of a *tunicated*, in its inner, of the nature of a *scaly* bulb. It abounds in an acrid, mucilaginous juice, with an alliaceous odour, and a bitter, acrid, nauseous taste. It is imported whole, or cut in slices and dried. The bulb is not of equal potency in every part. The outer, dry, scarious integuments are devoid of activity; the subsequent fleshy scales are the most powerful; while the internal young ones are mucilaginous, nearly insipid, and powerless. It is clear from this that the best mode of drying squill is to decorticate it by removing the outer segments, and carefully separating the intermediate large fleshy scales, to dry these quickly, and to leave the central ones as inefficient. The drying should be conducted quickly, but not by too high a temperature, lest some of the active principles be driven off. Putting the thick scales on sieves or willow-baskets in a moderately heated oven, or in a room fitted with a drying apparatus, is the best plan. Stringing them on threads and drying them slowly, by which they become paper-like and tasteless, is bad. The common method however is to cut the bulb into transverse slices, which, when dried, have a horny appearance, and are semi-translucent. In this case the active and inactive portions are blended together. After whatever means are used to dry them, it is necessary that the squills be kept in well-stoppered bottles in a dry place, as, in common with all bulbous plants, they quickly absorb moisture from the atmosphere. In the process of drying, four-fifths of the weight are lost.

The chief constituents of squill are—an acrid bitter principle (*Scillitin*), sugar, mucilage, salts of citrate or tartrate of lime, also phosphate of lime, tannin, and a volatile acrid principle, which in the process of decorticating fresh squill causes a flow of tears from the eyes, sneezing, &c., and severe itching, with burning pains of the hands and arms, yet without obvious swelling or inflammation. A scale of fresh squill applied to the skin rapidly excites rubefaction and vesication, like a sinapism. Squill in large dose is unquestionably poisonous, but in many cases it fortunately acts as its own antidote, by causing vomiting. But even in moderate doses it may still do much harm, by its stimulating effect, if prematurely employed, as it often is, as a popular or domestic medicine in the early stages of colds and coughs. It is for the second stage alone of these that it is suited. It augments the secretion from most mucous surfaces, and also stimulates the kidneys, and sometimes the skin. For the reason above stated, it is unsuited to inflammatory dropsies, but it is proper for the effusions occurring in leucophlegmatic subjects, depending on debility, and for general anasarca rather than local effusions. Its diuretic properties are increased by the previous moderate use of mild mercurials, and by uniting it with other diuretics, either vegetable or saline, and still more by adding bisulphate of quinia or other tonics. Its expectorant properties are greatly heightened by the addition of tonics, such as exist in the Mistura Cascarillæ Composita. Squill is a very improper emetic for young children, as it seriously irritates the coat of the stomach.

SCILLITIN, the bitter principle of squills (*Scilla maritima*). This is obtained by first inspissating the juice of the root, then treating it with alcohol, and after having evaporated the solution, dissolving the residue in water; to the solution acetate of lead is to be added, which gives a precipitate that is to be separated; afterwards sulphuretted hydrogen is to be passed into the solution, and it is finally to be evaporated. By this process scillitin is obtained, which has the following properties: it is colourless, friable, of a bitter taste at first, and afterwards nauseous and sweetish, and attracts moisture from the air. It is soluble in alcohol and in ether; its solution is not precipitated by acetate of lead. It is emetic and purgative, and may even occasion death.

SCIOPTIC BALL is a globe of wood about 5 inches diameter, with a cylindrical perforation 2½ inches diameter passing centrally through it, and having at one extremity of the perforation a glass lens. The globe or ball is, by means of screws, fixed in a socket, which is made in a board about 8 or 10 inches square, in such a manner that while it cannot fall out, it is capable of being turned on its centre, to a small extent, in any direction.

The board being screwed to a window-shutter, or to the vertical face of a building in which an aperture has been made for the reception of the globe, the rays of light from external objects, after being refracted in the lens, form pleasing images of those objects on the opposite wall of the apartment, or on a white screen placed in a vertical position to receive the light; the apartment being darkened in order that the images may be distinct. The images on a vertical screen being inverted, two arms generally project from the board, within the room, and carry a plane mirror which turns on an axis so as to allow the rays of light, after passing through the lens, to fall on a screen placed in a horizontal position: by this means the spectators are enabled to see the images in erect positions. [CAMERA LUCIDA AND CAMERA OBSCURA.]

When the construction of the building is such as to allow the ball and lens to be fixed at an aperture in the roof, a plane mirror being placed above it at an angle of 45 degrees with the horizon, so as to reflect the rays from external objects down on the lens, the images formed on a screen within the darkened apartment are more distinctly formed and more conveniently seen. An apparatus of this nature was formerly applied to the roof of a building connected with the astronomical observatories at Greenwich, Edinburgh, and Glasgow, for the amusement of visitors.

SCIRE FACIAS, is a writ used to enforce the execution of, or vacate, some already existing record. It directs the sheriff to give notice ("Scire facias," whence the name) to the party against whom it is obtained to appear and show cause why the purpose of it shall not be effected. A summons to this effect should be served on the party, whose duty then is to enter an appearance, after which a declaration is delivered to him, to which he may plead, or demur, the subsequent proceedings being analogous to those in an ordinary action. *Scire facias* may be resorted to,—

1. Where, the parties remaining the same, it is necessary to revive or set in operation the record.
2. Where another party seeks to take the benefit of it, or becomes chargeable, or is injured, by it.

Formerly, when a year and a day had elapsed since judgment was signed, the law presumed that the judgment had been satisfied; and execution could not issue against the defendant until he had an opportunity, by means of the notice given him under a *scire facias*, of appearing and showing any cause which might exist why execution should not issue against him. But a simpler, less expensive, and less dilatory method of proceeding was provided by the Common Law Procedure Acts, 1852 and 1853, the former statute having at the same time extended the period during which execution may issue, from a year and a day to *six years*. In case of a change by death, marriage, bankruptcy, or otherwise, in one of the parties to an action, the representative of that party may now enter a suggestion of the fact, and put himself in his place. The opposite party is also enabled to call upon the representative to do so, and if he fails to stop the proceedings. The proceeding by suggestion on the roll is adapted to the most simple cases of change in the parties to a suit. If it be not adopted, a writ of *Revivor*, as it is now called, may be issued, the object of which is the same as that of a *scire facias*. It is, however, directed to the party and not to the sheriff, as was the writ of *sci. fa.*, and it may be served anywhere by the party, and not as formerly by the sheriff of the county where the *venue* in the original action was laid. The subsequent proceedings in *Revivor* resemble those of an ordinary action.

The writ of *scire facias* is not itself abolished. In some cases it is still the only method of proceeding; for instance, to enforce a judgment against the *terre tenants* of a deceased judgment debtor. So when a plaintiff, having had execution by elegit, under which he obtains possession of a moiety of the rents and profits of the defendant's land, has had the debt satisfied by payment or from the profits of the land, *scire facias* may be brought to recover the land.

A *scire facias*, again, is the only proceeding for the purpose of repealing letters patent by which the crown has made a grant injurious to some party, as where he has granted the same thing which he had already granted to another person; or a new market or fair is granted to the prejudice of an ancient one, &c. The sovereign may also have a *scire facias* to repeal his own grant, and any subject who is injured by it may petition the crown to use the royal name for its repeal. A man may have a *scire facias* to recover the money from a sheriff who has levied under a *fieri facias* and retains the proceeds.

SCIRRHUS. [CANCER.]

SCLEROTICUM. [ERGOT.]

SCO'LIA (from σκολιός, crooked) were short drinking-songs, which were invented and cultivated by the ancient Greeks. The origin of the name "crooked songs" has been explained by the ancients themselves in a variety of ways, of which we shall mention only two. Some supposed that these songs were called scolia because they were not sung by the guests in succession, and in the order in which they lay on their couches, but irregularly, and without any definite order; others thought that the name referred to peculiarities in their metrical forms, or, which is the most probable of all, to certain liberties which the singer might take in delivering his song. The first of these two opinions, though not a probable account of the origin of the name scolion, yet contains the true account of the manner in which scolia were sung. Artemon ('Ap. Athen.,' xv.) and Plutarch ('Sympos.') distinguish three kinds of Scolia, namely, those which were sung in a chorus by a whole company, those which were sung by all the guests in succession, and those which were only sung by well skilled persons, who, when they ceased, called upon another member of the company to go on. But the name scolion seems, in the first two of these cases, to be applied improperly, as they must rather be considered as a kind of prelude to the real scolia, which is in fact implied in the description given by Plutarch. These drinking songs were generally accompanied by the lyre, which was handed by the last singer to his successor: in some cases, however, when persons were unable to play the lyre, a laurel or myrtle branch was handed to them. Scolia were first sung and composed by the Greeks of the Æolian race, and especially in Lesbos; but the custom was thence transferred into Attica, where it subsequently became a universal practice to sing scolia at repasts. The contents of these short songs—which, in the specimens still extant, seldom exceed four lines—varied according to time and circumstances. The metres in which scolia were written are of a lively and animated character, and, on the whole, resemble those used by the lyric poets of the Æolian school. Terpander is said to have been the first who wrote scolia, and he was followed by Alcæus, Sappho, Anacreon, Praxilla, Simonides, Pindar, and many others. A collection of Greek scolia still extant has been made by C. D. Ilgen, in his 'Σκολιά: id est Carmina convivialia Græcorum, metris suis restituta et animadversionibus illustrata,' Jena, 1798. The number of scolia in this collection is fifty, but they are not all real scolia.

(Compare Müller, *Hist. of Greek Lit.*, &c.; Bode, *Geschichte der Hellenischen Dichtkunst*, vol. ii., part. 2.)

SCOPARIN. ($C_{42}H_{22}O_{20}$?). This substance appears to be the diuretic principle of the *Spartium scoparium*. The concentrated infusion of this plant solidifies on cooling to a brownish-green jelly, which consists of scoparin, chlorophylle, and *spartein*. The chlorophylle is separated by water which dissolves the other two substances. During the spontaneous evaporation of this aqueous solution the scoparin separates in the form of small yellow crystals, which are slightly soluble in cold water, but very soluble in boiling water or boiling alcohol. Scoparin is inodorous and insipid, and without action upon test papers. Nitric acid transforms it into picric acid.

SCOPA'RIUS, CY'TISUS SCOPA'RIUS, or BROOM, a shrub extremely common on uncultivated ground, heaths, &c., of most parts of Britain. The young tops or twigs when bruised, have an unpleasant odour, and a disagreeable nauseous taste. The seeds are emetic, and probably contain cytisine, an alkaloid found in the seeds of the Cytisus Laburnum, which possesses emetic, and, in large doses, poisonous properties. But Dr. Stenhouse thinks the broom has a volatile narcotic principle, to which he gives the name of Spartiine. It also has an inert principle which he calls Scoparine. An infusion made with cold water is equally efficacious as the decoction, and much more palatable.

Broom tops boiled in water form a decoction which acts both on the bowels and kidneys. It is unquestionably a valuable diuretic, and many obstinate cases of dropsies have yielded to the use of this indigenous remedy which had resisted other means. Its diuretic properties may be increased by the addition of juniper berries and dandelion, to form the decoction, as now directed in the Pharmacopœia, and by adding to each dose, acetate, tartrate, or bitartrate of potash.

SCORDEIN. An aromatic non-azotised yellow substance found in the *Teucrium Scordium*.

SCORE, in music, is a collection of all the vocal and instrumental parts of a composition, arranged on staves, one above the other, and bar for bar, presenting at once, to the eye of a skilful musician, the effect of the whole band as the composition proceeds.

SCORPIUS, or SCORPIO (the Scorpion), a constellation of the zodiac, lying between Libra and Sagittarius, and bounded north and south by Ophiuchus and Lupus. It contains one star of the first magnitude, which with Spica Virginis, and Arcturus, forms a conspicuous triangle. As noticed in LIBRA, this constellation was formerly two signs of the Greek zodiac, the claws occupying the place of Libra. The story is that the chelæ or claws of the Scorpion were drawn back by Roman astronomers, and the constellation Libra added in honour of Julius Cæsar, at whose death a new star was said to have appeared in that part of the heavens. This story is alluded to, not very distinctly, by Virgil; Hyginus is totally silent about it, merely saying that his countrymen call one part of this constellation Libra. Manilius uses both Libra and Chelæ. Ptolemy does not mention Libra in his catalogue, though he does elsewhere. Dupuis contends, from its presence in the most ancient Indian and Persian zodiacs, that it is in reality as ancient as the rest: and indeed it is not unlikely that the Greeks may have derived their zodiac from some nation in which the term for scales was confounded with that for claws, either by a synonyme in the language itself, or by mistranslation on their part.

SCOT, from *sceat*, an Anglo-Saxon word originally signifying "a part" or "portion." It appears also, at least in composition, to have meant any sum paid; thus, sawl-sceat, soul-scot, or soul-shot, was the name for the ecclesiastical due payable at the open grave for the benefit of the soul of the deceased. Previous to the Reform Act, 2 Wm. IV., c. 45, in many boroughs the payment of scot and lot constituted a qualification as a voter for a member of parliament of the borough. Those who possessed such qualification at the time of passing the Act had, under certain conditions, their rights reserved to them.

The qualification consists in the payment of the rates which are allotted to each person as the proportion to be contributed by him. The criterion adopted for the purpose of ascertaining the scot and lot voters of a borough, is the poor-rate of the respective parishes comprised in it.

(Rogers *On Elections.*)

SCOTLAND, CHURCH OF. The constitution of this church is considered under the heads of GENERAL ASSEMBLY; PRESBYTERIANS; and SESSION, KIRK. An important portion of its recent history is narrated under the head FREE CHURCH. It remains only chronologically to mention the chief events in the history of the church. The main struggles of the Reformation in Scotland date at the middle of the 16th century. On August 1st, 1560, a convention parliament abolished the Romish hierarchy, and on 20th December of the same year, the first general assembly was held in Edinburgh. The tercentenary of this event was celebrated throughout Scotland and by Presbyterians in England on December 20, 1860. In 1561 the 'First Book of Discipline,' still an important part of the ecclesiastical code of the established church and the various sects into which the Presbyterians of Scotland are now divided, was compiled. The fundamental principles of the reformed church were passed into an act of parliament in 1567 (Act 1567, c. 3), with the title, 'The Confession of the Faith and Doctrine believed and possessed by the Protestants of Scotland, exhibited to the Estates of the same Parliament, and be their publick Votis authorised, as a Doctrine grounded on the infallible Word of God.' This constitution however had more reference to doctrine than to church polity. It condemned some of the more prominent features of the system of the abjured hierarchy, but did not contain any announcement of the new system of church government. The early constitution of the church as approved of by Knox and his friends, admitted of a difference of grades, certain clergymen being called 'Superintendents' of Provinces, which actually or nearly corresponded with the bounds of the old bishoprics. The Presbyterian polity was at length established by the act of 1592 (c. 114), called 'Ratification of the Libertie of the trew Kirk: of Generall and Synodall Assemblies: of Presbyteries: of Discipline.' In the mean time, those who had been the zealous clerical supporters of the reformation expected that the temporalities of the Roman Catholic church, or at least a considerable portion of them, would be applied to ecclesiastical purposes under the new system. They found however that the powerful laymen who assisted in the demolition of the old system had very different views. They spoke of this notion as "a devout imagination," and kept by far the larger portion of the spoil to themselves. After some hard struggles, in which the national feeling in favour of Presbyterianism was driven very nearly to an outbreak, Episcopacy was re-established by the parliament of 1612. In 1637, the celebrated Liturgy, concocted by Laud and West, on principles more nearly approaching to the Roman Catholic forms than those of the English Liturgy, created the convulsions which ended in the civil war and the re-establishment of Presbytery. On this occasion, great part of the assistance which the Covenanters received from the landed gentry was owing to their dread of a plan for restoring church lands to the hierarchy. On the restoration of Charles II., all the acts of the previous reign subsequent to the year 1623 were 'rescinded' or repealed, and consequently the Episcopal form of church government was restored. The persecutions that arose out of the attempt to enforce this system on a people who abhorred it the more, the more stringently it was enforced on them by penal laws, is well known in history. These laws were relaxed, but not in a manner to satisfy the Presbyterians, by the indulgences of James to all who differed from the established Episcopal church. At the Revolution the Presbyterian form was re-established. The followers of this system, who through the times of the hottest persecution did not ask to be *tolerated* but to be made an exclusive establishment, now thought that the hour was come for the "extermination" of their opponents; but they were told by King William that that was a word not in his vocabulary. In 1699 lay patronage was abolished by an act of the Scottish parliament. It was re-established by an act of the British parliament in 1710. This act created many disputes in the church; it occasioned the secession of 1736, elsewhere mentioned [ERSKINE, EBENEZER, in BIOG. DIV.], and it was the cause of the great severance in 1843 [FREE CHURCH]. In the same year with that severance an act was passed for modifying the right of patronage, called 'Lord Aberdeen's Act' (6 & 7 Vict. c. 61, passed 17th August, 1843): a measure said to have been passed for the purpose of satisfying the scruples of some clergymen who would not remain in the church as it was, but would be content with a less comprehensive measure than the Veto Act. The difference between these two systems was, in the first place, that the Veto Act was passed by authority of the church, its supporters denying that they required the interposition of any lay legislation. By that measure, the simple objection of a certain number of the male communicants without any reason given, was a cause of disqualification to a presentee. By Lord Aberdeen's Act, any members of the congregation may object to the presentee, stating their objections: and the church courts, if they think them good, whether in their general tenor, or with respect to the particular circumstances of the charge, may give effect to them by rejecting the presentee.

SCREEN, in architecture, a partition dividing off some portion of an interior or room from the rest, without similarly contracting or shutting up the space over head; a screen being a partition carried up only to a certain height, so as to admit a view beyond it. Screens are exceedingly beautiful internal features in the Pointed Gothic style, in which they were employed for a variety of purposes, not in churches alone, but in halls and other buildings.

In our larger churches the chancel was separated from the nave by a screen on which was placed the rood. [ROOD LOFT.] From the use to which it was subsequently applied this screen is, in our cathedrals, commonly known as the *organ screen*; it differs from others in being a double screen, so as to form a gallery above, and to admit of stairs leading up to it, in the space between two partitions.

The *altar screen* serves as a back wall to the choir, separating that division of the church from the presbytery or Lady-chapel behind it. [RETABLE.] That erected by Bishop Fox in Winchester cathedral is a splendid stone screen decorated with several tiers of canopied niches; and strikingly similar to it in design is the one by Abbot Whetehamstede at St. Alban's. Though not so designated, the stalls, &c., form lateral screens enclosing the lower part of the choir from the side aisles. Chartres cathedral contains a no less remarkable than fine example of such screen continued round the apsis of the choir, showing itself as a wall carried up to some height above the stalls, and divided into large compartments filled with sculpture. The fronts of chantries, small chapels, &c., in churches, may also be described as screens, most of which are pierced or open-work and tracery. The examples of this class are so numerous, that to particularise any of them would be almost superfluous; we may, however, mention that enclosing the monumental chapel of Prince Arthur, son of Henry VIII., in Worcester cathedral. The tomb of Henry VII., in his chapel at Westminster, is a gorgeous piece of screen-work, executed entirely in metal, and forming an insulated shrine on a very large scale. Westminster Abbey itself contains many fine studies of screens in its chapels and chantries. Of timber screens separating the chancel and altar end from the body of the building, many specimens are to be met with in country churches, and not a few of them are worthy of being studied for the beauty of their design.

Screens of a different character were employed in the halls of domestic and collegiate buildings, for the purpose of cutting off a passage leading to the butteries and offices. Such screens were almost invariably of oak or other wood, and the space over them and the passage behind served as a music gallery. Open-work was rarely if ever introduced into them, but they had generally two open arches, or sometimes square-headed doorways. Several specimens of this class of screens may be seen in Nash's 'Mansions of England in the Olden Times,' some of them, as that in the Hall at Audley-end, profusely adorned with carved panelling and other sculpture; and the one just mentioned is further remarkable for the centre compartment being carried up higher than the rest, though not quite to the ceiling. Other instances occur where the screen is carried up two stories, so as to form either a passage on the chamber floor, or a closed gallery with glazed or latticed apertures. Of this kind are those in the halls at Knowle and at Hatfield.

Screen is also employed to signify a colonnade or wall architecturally decorated, enclosing a court-yard in front of a building, as that for instance of the Admiralty, London. Screens of this kind are sometimes had recourse to in order to connect the advancing parts of a plan together, and prevent a façade being cut up into gaps. It is by this means that the buildings forming the river front of Somerset House have been connected together into a continuous façade by screens assuming the appearance of open Corinthian loggias above spacious bridge like arches. Eminently picturesque in themselves, those features serve to relieve all the rest, and to prevent the monotony that would otherwise take place in so extended a front.

SCREW. This mechanical power generally consists of two parts, one of which is a solid cylinder of wood or metal, on whose convex surface is formed a projecting rib or fillet, frequently called a *thread*, which passes spirally round in such a manner as constantly to make equal angles with lines parallel to the axis of the cylinder. The other is a cylindrical perforation through a block of some material, the surface of the perforation having on it a spiral groove corresponding to the projecting rib or fillet on the solid cylinder. The first of these parts is called a *convex* screw, and the other a *concave* screw, also a *male* and *female* screw.

A just conception of the nature of the line of direction taken by the rib or groove on the surface of the cylinder, may be obtained by drawing on a rectangular paper, whose breadth A B is equal to the circumference of the cylinder, any number of lines A B, C D, E F, &c., equidistant from each other, and perpendicular to the sides of the paper. Then joining the points A and D, C and F, &c., by right lines, and bending the paper on the surface of the cylinder, the lines A D, C F, E H, &c., will, by uniting at their extremities, become the continuous *helix* or spiral curve-line which the thread assumes. When the two parts are in action, the convex screw, being turned round in the other by a power applied at its surface, moves at the same time rectilinearly in the direction of its axis: occasionally however the convex screw is fixed, and then the other being turned about, it acquires at the same time a like rectilinear motion. In either case, the path described by a point on any thread during the time that the screw turns once on its axis, on being developed, becomes equal to A D or C F; and in the same time a point on the axis moves through a space equal to B D or D F.

Fig. 1.

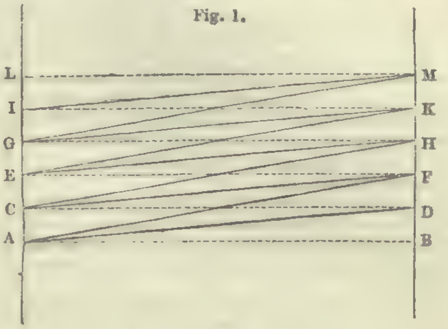

Fig. 2.

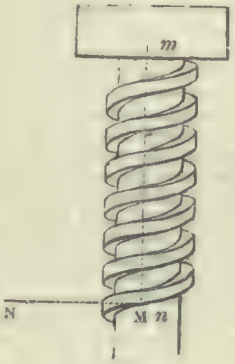


As a mechanical power, the screw possesses the properties of an inclined plane; for W representing a weight or pressure at one end of a convex screw, whose threads are thereby made to move in the grooves of the concave screw, let that weight be supposed to act in a direction parallel to the axis, and to be uniformly diffused among all the projecting threads which are at one time in the grooves; also let p be the part of the weight which presses in the direction mM on an elementary portion Mn of the side of a groove in the concave screw. Then Mn may be considered as a small inclined plane, making with mM an angle equal to A D B: and if q be a force which applied at M in the direction N M, touching a circle whose plane passes through the screw perpendicularly to the axis, would prevent the convex screw from turning round; the pressure on Mn and the counteracting force will be in the same circumstances as the weight of any body on an inclined plane and a sustaining power which acts in a direction parallel to the base of a plane, and, by the resolution of forces, the ratio between the pressure and the force will be as the base of the plane is to its height; that is, as A B to B D. Now an equal force q will be in equilibrio with the pressure p on every other elementary portion of the grooves in the concave screw; therefore, there being as many forces $= q$ as there are pressures $= p$, the whole weight W on the screw will be to the whole sustaining force, in the case of equilibrium as A B to B D; that is, as the circumference of the convex screw is to the distance between the threads when measured in a direction parallel to the axis.

But the screw, when applied as a mechanical power, is never used in its simple state; a lever or wheel is always fixed perpendicularly to the axis, and the moving or sustaining power is applied near the outer extremity of the lever, or at the circumference of the wheel. In this last case, the ratio between the moving-power and the resistance is as the distance between the threads of the screw is to the length of that circumference; and the velocity of a point on the axis is to that of a point on the circumference in the same ratio. The friction of a screw is however very great, and is frequently equal to, at least, the weight supported, for it will prevent that weight from descending when the moving-power is taken away.

An *endless* screw consists of two or more spiral fillets or threads on a rod which is capable of being turned on its axis by a power applied to the handle of a winch, or to a string passing over the circumference of a pulley attached to the rod. The threads work between teeth on the circumference of a wheel, so that while the revolution of the rod continues, the wheel turns on its own axis. If the radius of the winch or of the pulley on the screw-rod be 6 inches, and the distance between the threads of the screw be 1·10th inch, a power represented by unity at the circumference of the pulley will be in equilibrio, omitting the effects of friction, with a resistance expressed by $6 \times 10 \times 2\pi$, that is, by 376·99 (π being the half circumference of a circle whose radius is unity) applied at the threads of the screw or at the circumference of the wheel.

If the lines A F, C H, &c., were drawn on paper, and that paper were bent on the surface of a convex or concave cylinder, one spiral thread would be formed by the union of A F, E K, &c., at their extremities, and another by the like union of C H, G M, &c.: this is called a double-threaded screw, and it is evident that its mechanical power depends upon the ratio of A B to B F, while that of the single-threaded screw depends on the ratio of A B to B D; that is, with apparently an equal distance between the threads on both screws, the power of the latter is double that of the former.

From the high ratio which the resistance bears to the moving-power in the screw, the use of this machine for moving or compressing bodies is very great; it is also extensively employed in the construction of philosophical instruments for measuring small angles or distances. [MICROMETER.]

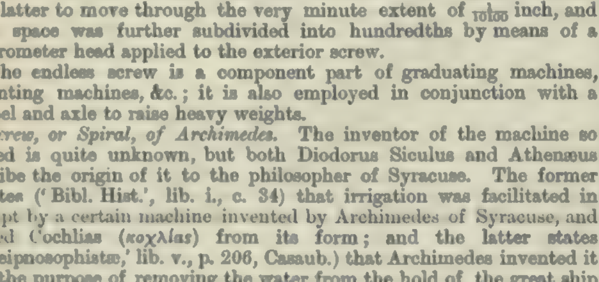
The ingenious screw-machine which was invented by Mr. Hunter, and is described in the 'Phil. Trans.' vol. 17, consists of one convex screw which works in the interior of another convex screw. The latter works in a concave screw which is fixed; and the former is capable of moving in a rectilinear direction only, being prevented from turning on its axis with the rotation of the exterior screw. Also the number of threads in an inch on the convex surface of this last is less by one than the number in an inch on the convex surface of the other: suppose the first number to be 10 and the other to be 11; then one revolution of the exterior screw would cause the whole machine to move forward through a space equal to $\frac{1}{10}$ inch, but in the same time the interior screw is carried backward through $\frac{1}{11}$ inch. Therefore the forward motion of this last is equal to $\frac{1}{10}-\frac{1}{11}$, or $\frac{1}{110}$ inch; and to produce an equal effect in a simple screw, the latter should have 110 threads in an inch.

Mr. Barlow of Woolwich mentions a compound machine of this kind in which the exterior screw had 100 threads in an inch, and the interior screw 101 threads; therefore one turn of the machine caused the latter to move through the very minute extent of $\frac{1}{10100}$ inch, and this space was further subdivided into hundredths by means of a micrometer head applied to the exterior screw.

The endless screw is a component part of graduating machines, counting machines, &c.; it is also employed in conjunction with a wheel and axle to raise heavy weights.

Screw, or Spiral, of Archimedes. The inventor of the machine so called is quite unknown, but both Diodorus Siculus and Athenæus ascribe the origin of it to the philosopher of Syracuse. The former relates ('Bibl. Hist.', lib. i., c. 34) that irrigation was facilitated in Egypt by a certain machine invented by Archimedes of Syracuse, and called Cochlias (*κοχλίας*) from its form; and the latter states ('Deipnosophistæ,' lib. v., p. 206, Casaub.) that Archimedes invented it for the purpose of removing the water from the hold of the great ship which was built by King Hiero of Syracuse. Vitruvius ('De Architectura,' lib. x., c. 11) describes the machine under the name of cochlea. He says that it consisted of four or eight laths bent spirally, and fixed at one edge against the axle, so as to form as many winding channels about it; and that the whole was covered by a cylindrical case, formed of planks, nailed over the exterior edges of the laths. The lower extremity was immersed in the water, which, rising along the channels by the revolution of the machine on its axis, was discharged at the upper extremity. Vitruvius adds that it was turned by men walking on its outer circumference, probably on the conical surface of a bevelled wheel fixed to the axle.

By the account which Vitruvius has given of its disposition, the spiral laths were placed nearly at an angle of 45° with the axle, and the latter was inclined to the horizon in an angle of 36° 52′. The cause of the ascent of the water, and the limits of the inclination of the axle to the horizon, will be seen from the following details which refer to the modern form of Archimedes's spiral as it is also called. It may consist of either a flexible tube open at both ends and wound spirally on the exterior surface of a cylinder; or it may be a plate of metal coiled about an axis, like the threads of a screw, and enclosed within a hollow cylinder so as to be completely water-tight. The machine is fixed in an inclined position, with its lower extremity immersed in the water which is to be raised. While it is at rest the water occupies the lower part between two of the threads or bends of the spiral, at bottom; but, when turned on its axis, this part of the machine being made to ascend, the water will by its gravity be caused to descend into the lower part between the next bends of the spiral, while in reality it rises, with respect to its former position, in consequence of the rotation of the tube, or bends, within which it is contined. Thus the water continually proceeds towards the upper part of the machine, from whence it is discharged into a reservoir placed to receive it.



It is shown, by writers on hydraulics, that this machine cannot raise water when the angle which a line drawn centrally on the spiral bends makes with planes parallel to the base of the cylinder is greater than the angle which the latter makes with the horizon; and it is recommended that, in practice, the angle which the axis of the cylinder makes with the horizon should be between 40 and 60 degrees. Such a machine is particularly useful when the water is mixed with gravel, weeds, and the like, which would spoil the action of a common pump. For computations concerning the force requisite to turn the machine, and the quantity of water which it will raise in a given time, see Gregory's 'Mechanics,' vol. ii.

A machine consisting of a pipe wound spirally about the surface of a cylinder, or cone, which is made to revolve about its axis when the latter is in a horizontal position, is called a *spiral-pump*. At one extremity of the spiral, water and air in nearly equal quantities being allowed to enter, the former will, in consequence of the revolution, be forced up an ascending pipe which may be attached at the other extremity.

The Archimedian screw has been occasionally employed in modern times to raise water from docks, basins, &c.; and it might be used to raise globular bodies, as cannon balls, from one level to a higher, as from the hold of a ship to the top of a wharf. A similar machine, having the spiral detached from and revolving within the cylinder which is about it, is also used. It is said to raise more water than the usual screw, but it cannot be elevated at a greater angle with the horizon than 30°, and its action is more easily impeded by the sand or gravel which is frequently mixed with the water.

For the application of the screw to navigation, we must refer to STEAM NAVIGATION.

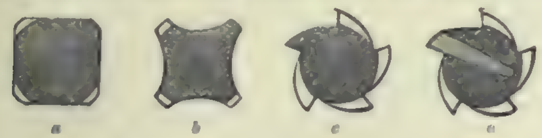
SCREW-JACK, a portable machine for raising great weights by the agency of a screw. Portable jacks, which are sometimes worked by a rack and pinion instead of a screw, are used for raising heavy carriages; the head of the jack being placed under the carriage, and raised by turning the screw with a lever. The "Universal Screw-Jack" is a great improvement on the common machine, as it allows lateral as well as vertical motion. In it the nut in which the vertical screw works is fixed in a carriage resting on the framework that forms the base of the machine, and capable of being moved upon it by means of an horizontal screw turned by a ratchet lever. This kind of jack is particularly useful on railways, where it affords a simple means of lifting a carriage or engine that may have run off the rails, and then moving it laterally until the wheels are in their proper position over the rails.

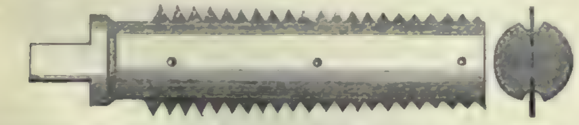
SCREW MANUFACTURE. The blanks for ordinary screws are sometimes made of round rolled iron, cut into the required lengths, and pinched when red-hot between a pair of dies in the chaps of a vice; while the heads are formed with a hammer, or the stamp of a fly-press. Another plan is to form the blanks of iron wire, cut by a machine, and have the heads struck up in a die without the application of heat. After forming the head, the next process is filing or turning the necks and heads in a lathe; after which the nick, or groove to receive the end of the screw-driver, is cut with a circular saw. The cutting of the worm is sometimes performed in a lathe, the blank being fixed in a chuck, and projected during its revolution between a pair of stationary cutters; the longitudinal motion of the blank, and the inclination of the thread, being determined by a regulating or pattern screw attached to the mandril. Small screws are frequently wormed by a similar apparatus turned by a winch-handle attached to the mandril; and sometimes by means of a steel tap-plate. In another plan the worm is formed by means of a pair of stationary cutting dies; between which the blank is projected by an apparatus which gives it an alternating rotatory motion. The dies themselves regulate the size of the thread, without the use of a pattern screw, and they must therefore be changed for every variety of screw. The best screws are made to taper slightly from the head downwards.

Several attempts have been made to produce screws by *casting*. In the ordinary method, the chief obstacle in the way of casting screws consists in the difficulty of removing the pattern from the mould. Mr. Maullin has devised a method of overcoming this difficulty by an apparatus for *screwing* the patterns (of which a great number might be used together) out of the mould, so as to leave the impression of the thread uninjured.

Screw-bolts and other screws for working in metal are manufactured in a similar manner to those for working in wood, when the number required is sufficient to justify the expense of adjusting the machinery. When this is not the case, they are, if small, often cut by hand, without the aid of a lathe. The die, or instrument for cutting an external screw, resembles a common nut, but is usually divided into two parts, which are fitted into an iron stock or die-frame, with long handles. Notches are cut in the die, across the direction of the threads, in order to produce cutting angles, and to afford room for the escape of the portions of metal removed in cutting the worm. The die, which is formed of steel, and well tempered, is inserted in the die-stock, with its two halves a little distance apart, but capable of being brought together by regulating screws fixed in the die-stock. The bolt to be made into a screw is fastened in a vice, while its end is placed in the die. The operator then proceeds to turn the die-stock, so as to worm the die on to the bolt; not by a continuous motion in one direction, but by a series of turns backwards and forwards. When the die has proceeded as far as the worm is required to extend, it is taken off, screwed up a little closer, and again applied in the same manner; the process is repeated, closing the die a little after each operation, until the worm is cut to the required depth. In working a similar apparatus by machinery, the dies are sometimes made in four pieces, the die-frame is stationary, and the bolt or screw-pin itself revolves. In this case the rotation is continuous, but in other respects the operation resembles that described. In cutting large screws, especially with a square thread, a steel cutter is sometimes used with the die, whether tufned by hand or fixed in a lathe. Very small metal screws are cut by a steel tap-plate, wormed and notched in a similar manner to the dies above described, but having several holes varying slightly in size; the worm being formed progressively, by using at each operation a smaller hole than at the preceding one.

Hollow or interior screws are commonly cut by means of a steel tap, which is simply a screw of which great part of the worm is removed by filing flat faces along its whole length, the angles left by this operation forming a series of obtuse cutters. The head of the tap is squared, to fit into the middle of a long handle, by which it can be turned with considerable purchase. The taps for cutting screws in wood are commonly fluted on the sides, to make them cut the more readily, and to afford more room for the escape of the cuttings. The tap invented by Mr. Jones answers the purpose of a tapering tap for commencing the screw, and a cylindrical one for completing it: the lower part being tapered, while the upper is left cylindrical. The tap is shown at *c*, more adapted for cutting than either *a* or *b*, which are the more usual forms. In large taps of this kind a steel cutter may be inserted, as shown in the section *d*, at the commencement of the cylindrical portion of the tap; the cutter being made to project a little, so that the tap follows it without difficulty. An ingenious kind of tap for cutting a square-threaded screw consists of a hollow screw of steel, having a hole drilled obliquely from the front end of the thread to the hole in the centre of the tap. The edges of this oblique hole, being made sharp, cut their way through the wood when the tap is turned round: while the hole itself forms a channel by which the cuttings escape into the cavity in the centre. For cutting internal screws in wood, where great accuracy is not required, the tap invented by Mr. Siebe, represented in the following cut, is useful. Though the wooden part is cylindrical, the steel plate tapers towards the end that enters the hole, in order that, by the first teeth projecting but little, the instrument may cut gradually. A groove is cut on each side of the tap, where the plate is inserted, to afford room for the escape of the cuttings; and the upper end of the cylinder is made flat or square for the purpose of fitting the lever by which it is turned.





The large iron screws used in vices, presses, waggon-jacks, &c., are formed by means of dies, turned with immense power by very long levers; the thread being made without cutting, by indenting and squeezing up the metal. In the ordinary method of cutting screws in a lathe, the size of the worm, or the distance between the threads, is regulated by a pattern screw, and cannot be varied from it. An ingenious machine is used in the Woolwich dock-yard for cutting a great variety of different screws from one pattern.

In making screws for mathematical or astronomical instruments, where the greatest accuracy is essentially necessary, it is especially desirable to avoid the risk of error arising from irregularities in the pattern screw, or in any part of the machinery used. The late Mr. Holtzapffel was highly skilled in this art; but Mr. Whitworth has recently carried it to a degree of refinement never before attained.

SCREW-PILE. [PILE ENGINE.]

SCREW-PRESS. This machine offers great facilities for the application of power; as the force applied may be almost infinitely multiplied by increasing the length of the lever by which it is turned, and diminishing the distance between the threads. It is also very convenient in cases where a continued pressure is required; because, in ordinary cases, the friction of the screw is too great to allow it to run back on the removal of the power by which it is turned. In the common screw-press the articles to be pressed are laid upon a stationary *bed*, forming the base of a strong frame, in the upper cross-bar or *head* of which a nut is firmly secured. The screw works up and down in this nut, and to its lower end is attached the *follower*, or moving piece which presses on the substance operated upon. The connection between the screw and this piece is such that the follower rises and falls, but does not turn round with the point of the screw; and the steady motion of the follower is provided for by making it fit closely to the side-pieces or cheeks of the press, which therefore act as guides. At the lower end of the screw there is usually a massive globular head, pierced with two holes at right-angles with each other, which receive the end of a long iron lever, by which the screw is turned. The best screw-presses are made of iron.

The great space required for turning a long lever is a serious inconvenience in some cases, and has led to the contrivance of several methods for turning the screw with great power by a more compact apparatus. In a press invented and patented by Mr. Dunn, the screw is turned by means of a short bent lever acting upon a ratchet-wheel fixed on the lower part of the screw. In another ingenious modification of the common screw-press, invented by Mr. Pouchée, a large cogged-wheel is fixed horizontally on the screw, just below the common head for receiving the end of the lever. A small pinion, having a square axis to receive a lever handle, is fixed on the platten or follower of the press, and works into the large cogged-wheel. This press is worked in the ordinary way until the screw is turned as far as the lever will conveniently move it. The bar is then removed, and the handle of the pinion put on, and by turning it the screw may be further depressed. In one form of screw-press for hot-pressing, the plates do not, as in those of the usual construction, need to be removed for heating; they being kept at the necessary temperature by hot air introduced into four hollow columns, which serve the purpose of cheeks to the press.

While the diminution of the size of the thread affords the means of increasing the power of a screw-press, it is attended by the serious disadvantage of diminishing its strength. This difficulty may be avoided by the use of a double or differential screw. The press may be made of the usual form, excepting that the lower end of the screw is cut with a finer thread than the upper part. This smaller screw is received into a nut resting on the follower, and capable of turning on it. The head for receiving the lever by which the screw is turned is in this case placed above the head or top beam of the press. When in use the nut is keyed fast to the screw, so that it turns with it; and the action is exactly the same as that of the common press. When the screw has been turned as far as it will go in this way, the key that connected the nut with the screw is removed, and the nut is keyed fast to the presser. The screw being again turned, the lower thread enters the nut, so that the presser is depressed only through a space equal to the difference between the width of the upper and lower threads of the screw. By making the two parts of the screw very nearly alike in fineness, the distance traversed by the platten may be diminished, and the pressure increased almost to infinity.

Screw-presses are occasionally made with more than one screw. In one arrangement of this kind the screws are stationary; and the nuts, which are fitted into the follower, are turned by means of cogged wheels driven by an endless screw laid horizontally on one side of the follower, and terminating at each end in a winch-handle. Mr. Brindley's press has several screws instead of one, each having a cogged wheel working into another fixed on a plain central shaft, which is moved by a winch and bevil gear.

SCREW PROPELLER. [PROPELLER.]

SCRIBES. In the article MOSES, in BIOG. DIV., this word has been used as a translation of the Hebrew word שׁוֹטְרִים, which in the authorised version is translated "officers." The word which is translated "scribe" in the English Bible is סֹפֵר, or in the Chaldee סָפֵר, meaning "a writer." It was applied to an officer of the king, or, as we should say, a "secretary of state" (2 Sam. viii. 17; xx. 25; 2 Kings xxii. 3); also to a "secretary-at-war," who had the enrolment of the soldiers under his care. (Jerem. lii. 25.) It was also used to signify men learned in the Jewish Scriptures. (Ezra vii. 6, 11.) The last was the meaning which the word came to have in the later ages of the Jewish state, or rather, as the Jews regarded all learning as contained in a knowledge of their sacred books, the word *scribe* was used to designate all men of learning. In this sense we find it in the Apocrypha and the New Testament, as the translation of the words *γραμματεὺς, νομικὸς, νομοδιδάσκαλος*, for the *lawyers* (as our version generally translates the last two words) were evidently the same persons as the Scribes. Their office was to administer the sacrifices and to explain the law. They had seats in the Sanhedrim, and were generally Levites. They, at least occasionally, wore long clothing (Mark xii. 38), which was effected by enlarging the border of their garment with a fringe. In the time of Christ they appear to have been for the most part Pharisees, but they did not form a sect.

(Winer's *Biblisches Realwörterbuch*, art. 'Schriftgelehrte.')

SCRIPTURE (γραφή, *scriptura*). This word means simply a *writing*, but it has long been used to designate the sacred books of the Old and New Testament. It is thus repeatedly used in the New Testament in reference to the Old Testament, and in one passage Peter applies it to the Epistles of Paul, and very probably he meant to include under the word some of the other books of the New Testament which were then written. (2 Peter iii. 16.) The different forms in which this word occurs in the New Testament are "the Scripture," "the Scriptures," "the Holy Scriptures," "inspired Scripture." (2 Tim. iii. 16; compare Smith's 'Script. Test. to the Messiah,' chap. ii., note A.) The term *a Scripture* is also used for a passage in the Scriptures. (Apocrypha; Bible; Canon; and the titles of the different books of the Bible.)

SCROFULA, or SCROPHULA, the technical name for the disease that is popularly called "the King's Evil:" the origin of the latter term will be explained presently; that of the former is very obscure and uncertain. We find the word *scrofula*, or rather *scrofulæ* in the plural, employed for the first time to signify the present disease, or one supposed analogous to it in cattle, by Vegetius ('De Re Veterin.', lib. iii., cap. 23, ed. Schneider). It is generally admitted to be derived from the Latin *scrofa*, or *scropha*, "a sow," although the reason of the derivation is by no means clear. The same analogy, whatever it may have been, influenced also the Greek and Arabic writers in naming the disease, as the former call it χοιρὰς, or χοιράδες; and the latter *khanázir* (Avicenna, tom. i., p. 154; l. 36, p. 194; l. 30, vol. ii., p. 73, l. 12, ed. Rom., 1593, fol; Albucasis, 'De Chirurg.,' lib. i., cap. 22, p. 50, ed. Oxon., 1778, 4to.), both of which words are intimately connected with *swine*. The classical Latin term for the disease is 'struma' (Celsus, 'De Medic.,' lib. v., cap. 28, § 7; Pliny, 'Hist. Nat.', lib. viii., cap. 77), or 'strumæ' in the plural (Celsus, lib. i., cap. 9; Pliny, lib. xxii., cap. 16), which is also a word of which no satisfactory derivation has been given, as probably few persons will agree with Dr. Good in deriving it from στρῶμα, 'congestion,' or 'coacervation,' as of straw in a litter, feathers in a bed, or tumours in the body."

The vulgar English name applied to it, namely, "the King's Evil," commemorates the virtues of the *royal touch*, to which, from the time of Edward the Confessor till the reign of Queen Anne, multitudes of persons afflicted with scrofula were subjected. A similar custom prevailed in France; and miraculous powers for the cure of scrofula were likewise claimed for different Romish saints, for the heads of certain noble families, for the seventh son, and for many consecrated springs. The *royal touch* requires some further notice. That the kings of England for several centuries actually exercised their touch for the cure of scrofulous complaints is proved by abundant historical authority; and scarcely any of our old historians, who wrote during a period of at least five hundred years, have omitted taking notice of this strange and unaccountable fact. We have not room here to give the evidence fully, and must refer those who wish to inquire more deeply into the subject to 'A Free and Impartial Inquiry into the Antiquity and Efficacy of Touching for the King's Evil,' 1722, by William Beckett, an eminent surgeon; 'Charisma, sive Donum Sanationis: seu Explicatio totius Quæstionis de Mirabilium Sanitatum Gratiâ, in quâ præcipuè agitur de solenni et sacrâ cui Reges Angliæ, ritè inaugurati, divinitus medicati sunt,' &c. &c., 1597, by William Tooker, afterwards dean of Lichfield; 'Charisma Basilicon, or the Royal Gift of Healing Strumæs, &c.' 8vo., Lond., 1684, by J. Browne; 'Several Chirurgical Treatises,' Lond., 1676, fol., and 1719, 8vo., 2 vols., by Richard Wiseman, principal surgeon in the army of Charles I., and serjeant-surgeon to Charles II., whom Haller ('Biblioth. Medic. Pract.,' tom. iv., p. 399) calls "insignis certe et peritissimus chirurgus." The question is examined at some length by Bishop Douglas, in his 'Criterion; or Miracles Examined,' &c. &c., p. 191, ed. 1754, who, while he denies the alleged miraculous powers, fully admits the reality of the cures. See also Colquhoun's 'Isis Revelata: an Inquiry into the Origin, Progress, and Present State of Animal Magnetism,' Edin., 1836, 2 vols. 8vo., who also allows (vol. i., p. 87) "the sanative efficacy of the process," but connects it with the phenomena of animal magnetism. Among the most curious parts of the subject, it may be mentioned that the old Jacobites considered that this power did not descend to Mary, William, or Anne, as they did not possess a full hereditary title, or, in other words, did not reign by divine right. The kings of the house of Brunswick have, we believe, never put this power to the proof; and the office for the ceremony, which appears in our Liturgy as late as 1719, has been silently omitted. The exiled princes of the house of Stuart were supposed to have inherited this virtue. Carte, in the well-known note to the first volume of his 'History of England,' mentions the case of one Christopher Lovel, who, in 1716, went to Avignon, where the court was then held, and received a temporary cure; and when Prince Charles Edward was at Holyrood House, in October, 1745, he, although only claiming to be prince of Wales and regent, touched a female child for the king's evil, who in twenty-one days is said to have been perfectly cured.

The history of this delusion carries with it a great lesson. It is very evident that the changed circumstances either of body or mind in which persons who submitted to the royal touch were placed produced the favourable results which have been recorded. It has been the same with popular systems of medical treatment up to the present day. The beneficial action of some agent is assumed, quite independent of any inquiry into the fact of its possessing any curative power at all, and the other circumstances by which the cured person is surrounded, which have really effected his cure, are entirely overlooked.

Scrofula is defined by Dr. Good ('Study of Med.') to be, "indolent glandular tumours, frequently in the neck, suppurating slowly and imperfectly, and healing with difficulty; upper lip thickened; skin smooth; countenance usually florid;" which agrees almost exactly with the definition given by Cullen in his 'Nosology.'

Later writers have, however, given a more extended view to the term scrofula, or scrofulous, and made it to include that general state of the system of which the indolent glandular tumour is but one symptom. The swellings and ulcerations which are so common in scrofula are found to be connected with alterations in the nutrition of the tissue of a similar kind to those which take place when tubercle of the lungs is present. [Phthisis.] Hence some writers have described a state of the whole system which they have called tuberculosis, in which either scrofula or pulmonary consumption occurs. It seems now agreed by the best pathologists that the same general state of the system which produces tubercle in the lungs produces the various forms of scrofula, including the indolent swellings of the definition of Good and Cullen. On this subject Mr. Paget, in his 'Surgical Pathology,' makes the following remarks:—"'Scrofula,' or 'struma,' then, is generally understood as a state of constitution distinguished in some measure by peculiarities of appearance even during health, but much more by peculiar liability to certain diseases, including pulmonary phthisis. The chief of these 'scrofulous' diseases are various swellings of lymphatic glands, arising from causes which would be inadequate to produce them in ordinary healthy persons. The swellings are due sometimes to mere enlargement, as from an increase of natural structure, sometimes to chronic inflammation, sometimes to more acute inflammation or abscess, sometimes to tuberculous disease of the glands. But, besides these, it is usual to reckon as 'scrofulous' affections certain chronic inflammations of the joints; slowly progressive 'carious' ulcerations of bones; chronic and frequent ulcers of the cornea, ophthalmia attended with extreme intolerance of light, but with little, if any, of the ordinary consequences of inflammation; frequent chronic abscesses; pustulæ, cutaneous eruptions frequently appearing upon slight affection of the health or local irritation; habitual swelling and catarrh of the mucous membrane of the nose; habitual swelling of the upper lip.

"Now these and many more diseases of the like kinds are amongst us, both in medical and in general language, called scrofulous or strumous; but though many of them are often coincident, yet it is very difficult to say what all have in common, so as to justify their common appellation. Certainly they are not all tuberculous diseases. Little more can be said of them than that, as contrasted with other diseases of the same forms and parts, the scrofulous diseases are usually distinguished by mildness and tenacity of symptoms; they arise from apparently trivial local causes, and produce, in proportion to their duration, slight effects; they are frequent, but not active. The general state on which they depend may be produced by defective food, with ill ventilation, dampness, darkness, and other depressing influences; and this general state of constitution, whether natural or artificially generated, is fairly expressed by such terms as 'delicacy of constitution,' 'general debility,' 'defective vital power,' 'irritability without strength.' Such terms, however, do not explain the state that they express; for they all assume that there are in human bodies different degrees of vital power, independent of differences of material, which is at least not proved.

"Such is the vagueness of 'scrofula' and of the terms derived from it as commonly used in this country. They include some diseases which are, and many which are not, distinguished by the production of tuberculous matter. It has been proposed, but I doubt whether it be practicable to make 'scrofulous' and 'tuberculous' commensurate terms; as at present generally employed the former has a much larger import than the latter. The relation between the two is, that the scrofulous constitution implies a peculiar liability to the tuberculous diseases and they often co-exist. These differences are evident in that many instances of scrofula (in the ordinary meaning of the word) exist with intense and long continued disease, but without tuberculous deposit; that as many instances of tuberculous disease may be found without any of the non-tuberculous affections of scrofula; that as Mr. Simon has proved, while the diseases of 'defective power' may be experimentally produced in animals by insufficient nutriment and other debilitating influences, the tuberculous diseases are hardly artificially producible; that nearly all other diseases may co-exist with the scrofulous, but some are nearly incompatible with the tuberculous.

"Now whether we disuse or still use in its vagueness the term 'scrofula,' we may make a group of the 'tuberculous' diseases, defined by the peculiar morbid product of which I have described the chief characters. Only at present we must be content, I believe, to be sometimes in doubt whether the substance found in lymphatic glands and commonly known as scrofulous matter be truly tuberculous matter or degenerate lymph or pus."

In the case of glands affected with what is called scrofulous inflammation, the same peculiar exudation is observed as is found in the lungs of those who are affected with phthisis.

This exuded matter generally presents a yellowish or dirty-white colour and varies in consistence from a substance resembling cheese to that of cream. It is sometimes soft in one place and hard in another. It also presents itself in masses of various sizes, from a millet seed to a hen's egg. It is friable on pressure and may break down into a pulpy matter. If a small piece is squeezed between two pieces of glass and placed under a microscope it presents a number of irregular-shaped bodies, varying from the $\frac{1}{3000}$th to the $\frac{1}{1200}$th of an inch in diameter. These bodies contain from one to seven granules, and are unaffected by water, but rendered transparent by acetic acid. These have been called tuberculous corpuscles. They are surrounded with minute points or granules, which are more abundant in the softer tuberculous matter. These corpuscles are often accompanied by deposits of mineral matter, consisting of phosphate and carbonate of lime. They occur, for the most part, in young persons, and may occur in any part of the body; but they are most frequent in the lymphatic glands. After these parts the fibrous textures are most frequently attacked, as the lungs and serous surfaces. These exudations are very slow in their progress, and are thus distinguished from the exudation of ordinary inflammation. They exhibit little or no tendency to the production of perfect cells or normal tissues, and the cells are slowly formed and slowly break down. They have little tendency, when once formed, to absorption; but show a great tendency to breaking up and ulcerating.

Scrofula, though not a contagious disease, is unquestionably hereditary; and hence very generally dependent upon a peculiar diathesis. Yet, like many other hereditary diseases, it is also occasionally generated as a primary affection, without any hereditary taint that can be discovered. When it occurs as a primary or ingenerated affection, it is by no means always limited to any particular temperament or habit of body. But where scrofula appears hereditary, and especially where it does not show itself very early, it is often accompanied with a peculiar constitution. "The character of a scrofulous child," says Sir Astley Cooper, "is as follows:—You will find the skin thin, if you pinch it, which is quite different from the skin of children who are not scrofulous; in them the skin is solid and dense, and the fibres strong; but in scrofulous the skin is thin, and the vessels may be seen meandering under it; and it is on this account that persons with this disease frequently have a rosy colour, arising from the thinness of the skin, which allows the vessels to be seen under it. The hair is also light coloured. If you observe, in a family of five or six children, one among them who has a delicate thin skin, with light hair and complexion, you will find that if they are all exposed to the same causes, they will escape from any scrofulous affection, with the exception of the one stamped by nature, and that this, during its growth, will be affected by the disease. The hair is also extremely fine, the eyelashes long, the pupils dilated, and the fingers are what is called clubbed, similar to the fingers in phthisical persons, that is, they are extremely long and thin, but at the extremities are broad and flat. The upper lip is of considerable thickness, and this is a mark of debility."

In considering the causes of a disease so deeply rooted in the constitution as scrofula is universally acknowledged to be, it is necessary to direct our attention to circumstances very remote in the history of those who are its subjects. The foundation of a scrofulous habit is frequently laid during the fœtal state, by the transmission of that peculiar organisation of the frame from parents who themselves possess it. Scrofula is also observed to originate in the healthy offspring of healthy parents, under certain circumstances, the principal of which are habitual exposure to cold and damp, privation of free air and light, and want of healthful exercise. A moist, cold, and variable climate, like that of Great Britain or Holland, is particularly favourable to the development of scrofula; in proof of which it is sufficient to adduce the great prevalence of the malady in both of those countries. A very cold or a hot climate, on the other hand, serves rather to protect us against scrofula; the former, dry and bracing, invites to exercise, and promotes digestion, and thus strengthens the system; while the latter favours the excretions, particularly that of the skin, and preserves the body from those sudden changes of temperature which in our island so often lay the foundations of scrofulous affections. Among the causes which appear to give rise to scrofula in children, are the practices of rearing them by the hand and suckling them too long; two extremes, both of which often lead to the same result,—the imperfect nourishment of the child. Another cause of this disease is confinement in ill-ventilated apartments; for the deficiency of pure atmospheric air cannot be long endured, especially during youth, without the most injurious consequences. Acute diseases, especially those accompanied with cutaneous eruptions, as small-pox, measles, and scarlet-fever, are often observed to have the effect of producing the development of scrofula; and the more tedious

the convalescence, the more frequently do symptoms of this disease ensue.

The treatment of scrofula divides itself naturally into the preventive and curative. With regard to the former, it must be applied both to those who have a scrofulous tendency and those in whom it has not yet been developed. The progeny of scrofulous parents require the greatest care and attention, if an outbreak of some form or other of the disease is to be avoided. All writers on this subject recommend that the children of scrofulous parents should not be suckled by a scrofulous mother, and that a healthy wet-nurse should be secured. Where this is not possible, it is perhaps better for the child to take its mother's milk than to rear it by hand, attention being paid to the health of the mother during the suckling of the child. In the preventive treatment of scrofula it should be recollected that cold, moisture, bad or deficient food, and impure air, are the great factors of the tuberculous deposits. Children and adults should be warmly dressed, and no exposure to cold should be allowed unless under circumstances where the reaction of the system can be secured. Thus cold bathing and exercise in the cold air are commendable as long as the natural heat is kept up. A moist and cold atmosphere acts most unfavourably. Climates that are dry, and gravelly and chalk soils, are preferable to moist climates and clay soils. The food of those predisposed to scrofula should be nutritious. It should especially abound in the oleaginous element. Children should not be allowed to reject fat, and the taking butter, cream, and fatty food, where positive indigestion does not interdict, should be encouraged. Exercise regular and constant in the open air should be taken every day. This should be sufficient to employ the muscles, to increase the capillary circulation, to promote the function of the skin, and maintain healthy nutritionary change. Of all the causes of scrofula that of impure air from overcrowding and imperfect ventilation is the most constant and prevalent. It presses most heavily on the poor, because they cannot prevent it, but the more opulent suffer from it from their ignorance of its existence. Close rooms, beds with curtains, rooms lighted with gas, crowded assembly rooms, and places of worship, all contribute to bring on a state of the body from which there is too often no escape when once it comes on. In this respect the whole of the internal arrangements of the majority of houses in our towns and cities require reform. It is not till this subject is thoroughly understood by the great mass of the community, that the devastations of scrofula amongst our city populations will cease.

The *curative* treatment of scrofula may be divided into *constitutional* and *local* applications. With respect to the former, it would be impossible here to notice all the numerous remedies that have been recommended for the cure of this disease; we must be content with pointing out those that are most generally esteemed. Of all the remedies employed in the treatment of scrofula, perhaps none have enjoyed a greater reputation than mercurials; but it is only from their purgative and alterative effects that they prove beneficial, and not when they produce that powerful influence on the frame which so rarely fails to ensue from their free exhibition. Tonics are amongst the most valuable remedies; of these, cinchona is perhaps the most efficacious, and from the concentrated form in which it can now be exhibited (namely, the disulphate of quina), the most generally available. Other vegetable tonics and bitters have been administered with advantage in scrofula, such as calumba, gentian, and hop. Of the metallic tonics used in scrofula, iron is that which has been found the most beneficial; and the best forms of exhibiting it are the Vinum Ferri, the Tinctura Ferri Sesquichloridi, and the Ferri Sesquioxidum, in powder. Iodine, as prescribed by Lugol, is at present in considerable repute. It is successfully employed both internally and locally, in each of which modes it increases the action of the absorbents; and in the latter it likewise often induces suppuration of strumous tumours, and thus hastens their removal. Allusion has been made to the use of fatty food as a preventive of scrofula, and cod-liver oil has been found of no less value as a medicine. It may be combined with any other medicines or system of treatment that may be thought necessary. The evidence in favour of its use in most forms of scrofula is so decided, that it never ought to be overlooked as part of any general system of treatment. The use of baths in the treatment of strumous affections is of great value, the kind of bath to be made choice of being determined by the existing state of the patient. Sudden immersion in cold water, and especially sea-water, has long been an approved remedy in scrofula; but when the strength of the patient is so reduced that no kindly glow follows, and when there is decided feverishness, the cold plunge-bath is not admissible. In most cases the warm-water bath, and still more that of vapour, will be found highly soothing and restorative.

With respect to the *local* treatment, indolent scrofulous tumours, when the health is little reduced, may be dispersed or made to suppurate by continued pressure or by blistering, which can be employed when the situation of the swelling will not admit of pressure. In the treatment of scrofulous ulcers, the simplest and mildest dressings answer best. Cold spring water is a favourite application with many practitioners; and preparations of lead are, upon the whole, very convenient and useful applications, provided the solutions be used in a state of sufficient dilution to prevent irritation. Formerly, the extirpation of scrofulous tumours was advised, but this method is now considered as being for the most part injudicious and unnecessary, with the exception of diseased joints and a few other parts which frequently require being amputated for the sake of saving the patient's life. Caustics have been employed for the same purposes, instead of the knife; but as they effect the object in view less certainly, more painfully and tediously, and cause extensive ulcers, they are disused by all the best surgeons of the present day. Some authors advise making issues, and keeping them open, in order to prevent any ill effects from the healing of the scrofulous ulcers. Issues may perhaps be unnecessary for any purpose of this kind; but they are eminently useful as a part of the local treatment of scrofulous joints and abscesses. When all hope of recovering a diseased portion of the body is at an end, the question immediately presents itself whether such part ought not to be removed by an operation. In considering the propriety of amputation, it is necessary to determine how far the continuance of the affections brings the patient's life into hazard, and whether he has still sufficient strength left to undergo the operation. When another important joint, or a vital organ, as the lungs or bowels, is already the seat of incurable disease, such operation is nugatory, and in such cases unquestionably it should not be performed. Great caution however is required in making our final decision; for every practitioner of experience has seen instances where the symptoms of visceral disease appeared almost to preclude hope, and yet have yielded on the removal of the local irritation, and a cure has been the happy result.

(Cooper, *Surg. Dict.*; *Cyclop. of Pract. Med.*; Ancell, *Treatise on Tuberculosis*; Dr. Bennett, *Principles and Practice of Medicine*; Paget, *Surgical Pathology*; Lugol *on Scrofula*, by Dr. Rankin; B. Phillips, *On Scrofula and its Treatment.*)

SCRUPLE (*scrupulum*, diminutive of *scrupus*, a term for a sort of pebble, probably used in counting) is now used only as the third part of a dram, or the 24th part of an ounce, in the apothecaries' division of the troy pound. It was used originally as the 24th part of the Roman uncia; afterwards as the sixtieth part of an hour, or what is now called the minute. The sixtieth part of a minute was called scrupulum secundum, the sixtieth part of a scrupulum secundum was scrupulum tertium, &c., whence our terms second, third, &c. applied to the sexagesimal divisions of the minute. It is worth noting that the ancient form of the word is also scripulum and scriptulum, which might suggest a different derivation of the word as a weight or measure. It may be worth while to add, that the scrupulum is described by lexicographers as a small pebble, such as found its way between the sandal and the foot, whence the use of the word to denote a difficulty or objection.

SCUDO. [MONEY.]

SCULPTURE, in its strict sense, is the art of carving or cutting any material into a proposed form or shape. In its more general acceptation it is the art of representing objects by *form*; and is thus applied to carving, modelling (or the plastic art), casting, whether in metal or other materials, and to gem-engraving. Sculpture is practised in various ways; namely, in forming entire or insulated figures, as statues or groups, called in technical language, "the round;" or in representing objects more or less raised without their being entirely detached from a background. This latter is termed "relief," and the degrees of relief are defined by modern writers and artists by the expressions *alto-rilievo*, when the object is so salient as to be nearly "round;" *basso-rilievo*, when it is slightly raised from the background; and *mezzo-rilievo*, when a medium is preserved between the extremely high and the very flat "relief." There is another variety of this manner of working "basso-rilievo," which is only or chiefly found in Egyptian sculpture; the outline is sunk into the plane or ground, and the parts are then formed and rounded on the principle of basso-rilievo. By this mode of working there is usually no projection beyond the profile or face of the original ground; to gain effect therefore in this kind of *relieved intaglio*, the Egyptian artists frequently painted the sculpture.

It is not necessary to enter into a discussion of the various opinions respecting the comparative antiquity of the arts of painting and sculpture. Pliny's story ('Hist. Nat.,' xxxv. 12) of the daughter of Dibutades having traced the outline of her lover's profile on the shadow cast on the wall, and of this outline being afterwards filled in with clay by her father, would give the priority to drawing; and it seems obvious that drawing an outline must be antecedent to modelling, or cutting in *relief*; but a little consideration will suffice to establish the probability that *insulated* objects and figures were made in the very earliest times. So many materials offered themselves upon which the imaginative faculty could be exercised, that there can be little doubt that rude attempts at forming clay, or any other plastic substance, into a defined shape, were amongst the first exercises of human ingenuity; and the easy task of thus repeating or copying the real form of an object, compared with that of representing by lines (and on a flat surface) its partial and perspective appearance, is quite sufficient to lead to the inference that this was the earliest mode of imitation. The ancients appear to have availed themselves of every known material that was capable of being employed in sculpture. Pliny, Pausanias, and other writers supply some curious information on this subject, for, in describing works of art, they usually mention the materials in which they were executed.

For modelling, clay, wax, and stucco, or plaster, appear to have been universally adopted; and works of great antiquity formed of these substances, are still preserved. The clay model was usually baked, by which it acquired a hardness scarcely inferior to stone. Moulds were also made of clay, and being subjected to the above process, were safely used as forms into which softer substances could be pressed, and thus objects were multiplied without difficulty. The almost countless number of figures, bassi-rilievi, lamps, tiles, architectural ornaments, vases, domestic utensils, stamps, &c., which are found of this material (called *terra cotta*, baked earth), proves the extent of its employment in the earlier ages of art. The objects usually composed of terra-cotta are of small dimensions, but there are instances of its being used for works of considerable size. In the Museo Borbonico at Naples are two statues, of Jupiter and Juno, above six feet high, and two others, one of an actor and the other an actress, above four feet high. They were found at Pompeii. The larger figures are inferior in their forms to the others, but whether the faults of proportion arise from the shrinking or contraction of the clay in baking, or were errors in the original modelling, it is not easy to determine. The specimens of *terra-cotta* preserved in England are for the most part of small size; but there are some very beautiful objects, both for execution and subject, in the Townley collection of the British Museum. It appears highly probable that the ancients always, or almost always, painted their *terra-cotta* works. In many instances the colour still remains, and the draperies of figures, and portions of architectural ornament, often exhibit well preserved designs of border patterns. The employment of wax for modelling and casting can be traced to a very remote period. The Romans also employed it for making statues, or perhaps only busts. It was a custom in some families to preserve portraits of their ancestors made of wax. [PORTRAIT.]

A great proportion of the ornamental work, rilievi, &c., in the buildings of Pompeii is of *stucco* or plaster. Few collections of antiquities are without specimens of figures and ornaments modelled in this material. Some in the British Museum are examples of great delicacy and sharpness of execution. Many of them are painted; red is the prevailing colour.

The list of materials used for *carved* works comprises every substance, hard or soft, that could by possibility be employed for the purpose, including porphyry, basalt, granite, marble, alabaster, ivory, bone, and wood of all kinds. The three first named were used chiefly by the Egyptians, who seem, in all their monuments of art, to have worked with the view of securing the durability of their productions, employing, whenever they could do so, and especially for works of importance, materials likely to resist the action of the atmosphere. When the introduction of some of the superstitions of Egypt into Rome led to the adoption of the Egyptian style of sculpture, it became the fashion to execute works of art in the above materials; but this did not occur till the reign of Hadrian, before and after which time they are seldom met with.

The variety of marbles known and used by the ancients is almost infinite. (Pliny, 'Hist. Nat.,' xxxvi. 7.) Those preferred for their superior texture, colour, or applicability to sculpture, were, first, the Parian, which was found in the island of Paros. It is called also Marpessian, from the mountain from which it was brought; and sometimes Lygdinum or Lychneum, perhaps from its bright sparkling appearance. In the second rank was the Pentelic marble, which was procured from Mount Pentelicus, in the neighbourhood of Athens. It was highly esteemed by the sculptors of antiquity. Its colour, like that of the Parian marble, is white; but it usually has a cold bluish tone, arising from the grey, and sometimes greenish, streaks that run through it; while the general hue of the marble of Paros is warm and creamy. The Italians often called the Pentelic marble *marmo salino*, from the salt-like appearance of its grain or crystals. The marble of Mount Hymettus in Attica was also much esteemed; it resembled in colour the Pentelic. After the conquest of Greece by the Romans, this marble was imported in great quantities into Italy. Lucius Crassus introduced it most extensively in the decoration of a palace which he built on the Palatine; an instance of unusual luxury, which was much reflected upon at the time. The marble of Thasos seems to have been much used, especially for architectural purposes. It was employed for covering and encasing edifices, and for lining reservoirs and fish-ponds. The Italian marble was procured from Luna, in the range of mountains near which are the modern towns of Massa and Carrara. These quarries seem to have been unknown till about the time of Julius Cæsar, when they were extensively worked. The grain of the Carrara marble is finer than that of the Greek marbles above mentioned. Its colour is usually a rich white, and it bears a close resemblance to fine lump sugar. It is seldom found quite pure; veins and spots of black, grey, and red and yellow (oxides of iron) occur in it. The Romans also worked quarries in Africa which produced limestone and white marble with veins of pale grey. The quarries in Greece are no longer worked, and the chief, or it may be said, the only supply of statuary marble is at present from Italy. These were the principal white marbles which were employed by the sculptors of antiquity, and in which some of the finest remains of art are executed.

Among the varieties of wood in which objects were carved, we find oak, cedar, cypress, sycamore, pine, fig, box, and ebony. Cedar was thought to be very durable, and on that account was used, Pliny says, for images of the gods; the same author especially distinguishes cypress, cedar, ebony, and box, for their capability of resisting the injuries of time. (Plin., 'Hist. Nat.,' xvi. 40.) Pausanias saw several statues of wood during his travels in Greece, and the following instances will serve to show that this apparently humble material was employed for representing the most elevated personages in the ancient mythology. The statue of Apollo Archegetes was composed of ebony, as was the statue of Diana Limnitis. At Lacedæmon the statue of Venus was of cedar. A statue of Apollo made of box adorned the treasury of the Sicyonians in the Altis. In the temple of Castor and Pollux at Argos were their statues, those of their children, and of their mothers, all made of ebony. All these works in wood have perished, notwithstanding Pliny's observation, "Materiæ ipsæ æternitas" ('Hist. Nat.,' xiii. 5). A few however of smaller dimensions have been found in tombs. They are chiefly figures of Egyptian idols; and the wood of which they are made seems to be sycamore. Gold, silver, iron, tin, copper, lead (and their compounds), wax, and plaster, were all used for the purpose of *casting*. [BRONZE; FOUNDING.] A mixture of gold and silver, in the proportion of one to five, formed a composition termed *Electrum*. According to Homer, Helen presented to the temple of Minerva at Lindus, in Rhodes, a cup made of electrum, of the exact form and size of one of her own breasts. A mixture of copper and tin, with sometimes, but not always, small portions of other metals, formed what the Greeks called *Chalcos* (χάλκος); the Romans, *Æs;* and modern artists (from the Italians), *Bronze*.

There was a statue of Augustus of *amber;* and at the celebration of funeral ceremonies, as those in honour of Sulla, statues were sometimes made of *gum* and *aromatics*, as well as of other materials of the most combustible nature, as, for instance, of *hay*. Among the strange conceits of artists there is mention of a statue of the goddess of Love made of *loadstone*, which attracted a Mars of *iron*.

The union, or rather, combination of different marbles in the same work was called *polylithic* sculpture. When painting or colouring was resorted to, it was termed *polychromic* sculpture. These mixtures, which modern taste disapproves, were resorted to by the most celebrated artists of antiquity, and during the most flourishing period of sculpture and architecture in Greece. The various architectural members of their temples were picked out in red and blue; and the backgrounds, and frequently parts also of the sculpture itself, especially of rilievi, were coloured, to give further effect to the design. There can be no doubt that the peculiar circumstances of the climate must materially affect the appearance of this kind of decoration. What in the dull atmosphere of northern countries would, at the best of times, appear either dingy or tawdry, might easily be imagined to have a very different effect when seen clearly defined and relieved against a cloudless blue sky, and by the bright glare of a southern sun. The combination, under such favourable circumstances, of white marble, of which the temples were usually constructed, with simple though brilliant colours to indicate the mouldings or smaller members of the architecture and sculpture, sparkling with gold ornaments, certainly offers to the fancy a spectacle of surpassing splendour. It is not quite so easy to reconcile with *our* notions of propriety or good taste the mixture of materials for sculpture *within* buildings, where space, and sometimes light, if the temple were not open in the roof, would be wanting to dissipate the heaviness of effect which it is conceived such works would have. The introduction of foreign substances, either metal, precious stones, paste or glass, for eyes in statues and busts (of which examples occur in works even of the best period of art), is a species of barbarism that is quite unaccountable, and which the most zealous admiration of the genius of the Greeks cannot qualify or excuse. Such instances may however be considered exceptions to the rule of pure taste and simple feeling which is exhibited in the greater number of works by the sculptors of Greece; and modern experience will probably afford the best solution of what would otherwise seem an anomaly, by suggesting that the artists, even of those times, were occasionally dictated to, and their own better taste overruled by the caprice of their employers. It seems difficult to account otherwise for the strange circumstance of the lips as well as the eyes being inlaid. There is more than one example of this among the fine bronzes preserved at Naples.

Inscriptions were sometimes inserted into bronze statues; the letters being of a different metal from the figure. Cicero ('In Verr.,' Orat. iv.) speaks of an Apollo inscribed with the name of Myron. In the collection at Paris is a statue of a youth in bronze, on the left foot of which are the remains of two Greek words, ΑΘΑΝΑΙΑ . ΔΕΚΑΤΑΝ, in silver letters.

There was a very peculiar combination, rather referred to than described by ancient authors, by which shades or tints of colour were produced. Plutarch ('Symp.,' lib. v.) says that the sculptor Silanion made a statue of Jocasta, the wife of Laius, king of Thebes, in which she was represented dying. To increase the intensity of the expression of the countenance, the artist by an ingenious mixture of the metals of which the statue was composed, had produced a pallid appearance. This, he says, was effected by the addition of silver. Callistratus admires a bronze statue of Cupid by Praxiteles, for its elegant position, for the arrangement of the hair, its smile, the fire in its eyes, and, he adds, there was in its countenance a vivid blush. He observes the same thing, and with equal admiration and astonishment, of a statue by Lysippus. After describing the work generally, he says, the cheeks were coloured like the rose, and those who saw it were struck with surprise at seeing the bronze imitate the appearance of nature. The same remarkable effect is noticed in a bronze statue of Bacchus by Praxiteles. To these may be added a statue of Athamas at Delphi, mentioned by Pliny. He was represented sitting after the murder of his son Learchus, whom he had precipitated from a rock. This work, he says, was not entirely of iron; for the artist, Aristonidas, wishing to express the effect of confusion and remorse in the countenance of the king, used a mixture of iron and bronze, which should imitate in some measure the blush of shame. (Plin., 'Hist. Nat.,' xxxiv. 14.) Other notices might be quoted of this practice of the ancients. The writers who refer to these effects describe them as the result of study and intention on the part of the artists, and do not allow us to suppose that the mere accident of oxidation and decomposition produced them. The art seems to be quite distinct from that called *toreutic;* the latter being the union of distinct materials, easily removable, while the former is described as effecting an amalgamation which produced shades or tints. The few writers who speak of it are certainly general in their observations, and give no technical details of the manner of effecting these combinations; but this hardly justifies the entire rejection of their testimony as to what they saw. It is most probable that they coloured the statues after they were cast, as Pliny says was done in Egypt (xxxiii. 9). The different compartments and objects in the shield of Achilles ('Iliad,' xviii.) are described as exhibiting different colours. This however, whether the passage be Homeric and genuine, or interpolated at a later though ancient period, may have been a specimen of *toreutic* art. That the ancient sculptors increased, or imagined they increased, the effect of their productions in marble by adding colour, not only tradition but existing monuments testify. It is therefore not only possible but highly probable that they had some process with which we are unacquainted, by which they were able to produce some similar effects in their metal works.

Sculpture, as it was practised by the most ancient nations, must be viewed in a very different light from that in which we consider its employment in more modern times. With a comparatively uncivilised and unlettered people sculpture and typical art were the only means of representing ideas, and it had its origin almost in the wants of man. With later nations (even of a remote antiquity) art became in a degree a refinement; and then the various changes and improvements were adopted that now occasion the difficulty in distinguishing between original and engrafted styles.

The few notices that are scattered over the writings of the ancients are quite inconclusive as to a common origin of art; although certain received opinions upon the subject are occasionally met with. The very late date of the oldest of these writers, compared with the undoubted antiquity of the arts of design, accounts sufficiently for the difficulties they laboured under in collecting any trustworthy evidence on such points, and for the fables, exaggerations, and contradictions that abound in their statements. The adventures and works attributed to Dædalus, for instance, are a proof of the limited knowledge that existed of the first artist whose name occurs in the annals of Greek sculpture. The inventions and improvements in various useful arts due to a series of artists, and for which a single life would be insufficient, are nevertheless all ascribed to this one individual, who, after all, bore a name that in all probability was merely a general appellation given in early times to any skilful workman or artificer. In the same manner we find the introduction into Italy of the plastic art (simple modelling) attributed by Pliny to a refugee from Corinth at so late a date as about 600 B.C. The arrival in Etruria of Demaratus may have introduced changes or improvements in the fabric and decoration of vases. The names of the artists who are said to have accompanied him, Eucheir and Eugrammus, sound like epithets indicative of skill, rather than simple names of persons. Some writers speak of images having fallen from heaven. These several instances are referred to in order to show that even where tradition had supplied scattered and undefined notices of works of art of a remote date, they had become so subject to change and misrepresentation as succeeding generations received and in their turn again recorded them, that it would be vain to place any dependence upon them for a history of the origin of art. The inquiry into the precise time, the country, the circumstances when the first efforts in sculpture were made, must therefore be attended with almost insuperable difficulties. Not so the establishment, at a later period, of epochs marked by changes in style, and what artists call treatment.

The desire to perpetuate the memory of extraordinary events, of remarkable persons, or of their actions; to honour heroes and benefactors even during their lives, and to hand down to future ages the fame of their exploits, has been universal, and has rendered the arts by which such an end could be attained objects of universal interest. The first works applied to this purpose were no doubt marked by the greatest simplicity. The oldest and most authentic histories speak of monuments erected to mark the scene of any remarkable incident; and although, at the early periods referred to, these monuments were only composed of rude blocks, or mere heaps of stones, still to such a simple commencement may doubtless, in a great measure, be traced the origin of sculpture. Jacob set up a heap of stones at Bethel† mark the spot where he had had his dream or vision. (Gen. xxviii. 18.) A similar simple memorial of a pillar and a heap of stones commemorated the covenant entered into between Jacob and Laban. (Gen. xxxi. 44.) A similar monument was built over the grave of Rachel. (Gen. xxxv 20.) Joshua also set up a great stone under an oak, "to be a witness." (Josh. xxiv. 27.) As late as the time of Pausanias, about A.D. 170, certain of the Grecian divinities were worshipped under the form of rude blocks or mere columns, or stones set upright (Paus. vii. 22); and even in the present day the custom exists in some countries of setting up a heap of stones to mark the spot where any extraordinary accident, such for example as a death from violence, has occurred. These are frequent in Italy, where the passer-by usually adds another stone to the heap, at the same time repeating a prayer for the repose of the soul of the deceased.

It has been said that the history of sculpture is almost the history of idolatry. Religious feeling doubtless had its share in forwarding the progress of the arts; for man, even in his rudest state, always has a belief that good and evil emanate from some superior power; and, unable to comprehend a divine essence or spirit, has by degrees been led to offer his addresses to some visible object as its representative. But it seems probable that the first images or statues were of men rather than of gods: and thus that human idols preceded those of divinities. This supposition is strengthened by the fact that the heavenly bodies were the earliest objects of worship among the heathen nations; and the symbols that were afterwards dedicated to them were most likely merely pillars of a conical or pyramidal form, and not imitations of the human figure; and when such works are referred to and called "graven images" by Moses, it has ingeniously been supposed to be in allusion to the signs or hieroglyphics inscribed or cut on them. The sun was worshipped at Emesa under the form of a black conical stone with marks to represent the sun. (Herodian, v. 6; Gibbon, vol. i., c. vi.)

Traditional accounts of wonderful feats in arms, the real or fabled history of a conqueror, or a lawgiver, or the founder of a nation, led in all probability to the first attempts at making a portrait figure or image, which a rude and uninformed people, always attracted by the marvellous, associating with it actions of supernatural prowess, would soon learn to contemplate with feelings both of admiration and of awe. Extraordinary respect would lead to the payment of extraordinary honours; and the elevation of heroes into divinities would be attended with little difficulty when time had obscured the real existence of the personages and weakened the remembrance of their actions. The imagination would easily be worked upon while the eye contemplated these first rude attempts at form; and thus men would be elevated into gods.

The oldest idols of Egypt, no less than the monstrous images of the Buddhists and Chinese, were probably, in the natural progress of superstition, the fruits of a similar origin. The general forms once admitted and consecrated, as symbolical of divine attributes, were afterwards, in some instances, preserved from innovations by the influence of the hierarchical institutions; and thus was a barrier raised which for a long period was fatal to the progress of imitative art. We are accustomed to look to the East as the nursery in which art and science had their origin; and it is probable that much in the Egyptian and even in the Grecian religious systems was derived from this source. In the representations of the deities of the Hindus, the human form is frequently combined with the brute,—the union of intelligence and force; and, as we know was the case with the Egyptians, the Hindu artists seem to have been subjected to some limitations and to a prescribed type. In all statues and rilievi that remain, many of which must have been executed at distant periods, there is the same prevailing character of form, expression, and attributes; while out of the immediate pale of their mythological or sacred system they appear to have been less restricted; and some of the sculptures at Ellora and Elephanta exhibit a feeling for composition, and a power of expressing character, which make it surprising that their sculpture never attained higher excellence.

In turning to the inspired writings, we find allusion made to imitative art in the earliest period of history. The Israelites, after the Exodus, are warned against the superstitions and corruptions that had by degrees crept in and deformed their primitive simple forms of worship, and are exhorted to return to a pure devotion, as for instance in the book of Joshua (xxiv. 2, 14, 15, 23).

Rachel, when she left her father's house with Jacob and Leah, carried away "the images;" and Laban pursued them in order to recover objects upon which he seems to have set a high value. This, we believe, is the earliest notice in the holy writings of the existence of such things, and even here we have no particulars by which any idea can be formed of what they were like, or of what materials they were made. That they were small is evident from the circumstance of Rachel being able to carry them away unobserved, as well as from the facility with which they were concealed when Laban "searched all the tent, and found them not."

No remains of Hebrew sculpture are known; but as early as the time of Moses they had attained to a considerable proficiency in some of the most difficult processes of art. The setting up of the molten calf, and the making of the brazen serpent, are evidence of this. The earliest recorded names of sculptors are in the Old Testament; Bezaleel the son of Uri, of the tribe of Judah, and Aholiab the son of Ahisamach, of the tribe of Dan. (Exod., xxvi.) They were the artists appointed to make the ornaments of the Tabernacle, and their date is therefore about fifteen hundred years before the Christian era.

From the peculiar position held by the Phœnicians, and their character for enterprise and ingenuity, it is much to be regretted that we possess no specimens of their design. The coins of Carthage, a colony of Phœnicia, are of too late a date and of too insignificant a character to throw any light upon the condition of sculpture among the parent people. The recent excavations and researches of Mr. Davis on the site of Carthage, have not brought to light any productions of a kind to elucidate what is doubtful with reference to the attainments of the Phœnicians in the higher branches of sculpture and of the arts generally. We can therefore only estimate their proficiency in all ingenious pursuits from the encomiums so generally passed upon them by ancient writers. While the neighbouring people were in a state of primitive simplicity or profound ignorance, the Phœnicians seem, by a native industry and disposition to exertion, to have made themselves celebrated for their arts and manufactures. Their country was the great mart and magazine of the known world. The prophet Ezekiel apostrophises Tyre as a "merchant of the people for many isles."—"The ships of Tarshish," he says, "did sing of thee in thy market; and thou wast replenished and made very glorious in the midst of the seas." Homer ('Iliad,' xxiii. 743) calls them "the *Sidonians*, the skilful workers or artificers" (Σιδόνες πολυδαίδαλοι), when he speaks of them as having made an elaborately worked silver cup. Solomon sent to Hiram, king of Tyre, for workmen to build and decorate his magnificent temple; and the king sent him a "cunning" man, skilful to work in gold, silver, brass, iron, stone, and timber. (2 Chron. ii. 13; and 1 Kings, vii.) The building of Solomon's temple took place about one thousand years before the Christian era.

With the exception of the Hindus, our remarks have thus far been confined to those nations among whom sculpture is known to have been practised, but of whose art no monuments remain. We are now about to enter upon a more interesting field of inquiry. Sculpture had in its first stage (when, as we believe, each people who employed it originated it for themselves) fulfilled its purpose as a sign or a record. Afterwards it acquired an increased dignity from being used to represent objects claiming admiration or respect; and it was in this stage probably that valuable materials were first used for sculpture. The progress was easy to employing it for decoration, and the Babylonians and Hebrews made great use of it for this purpose. But as yet no practical knowledge has been gained with respect to its progress as an art of design; of the changes from primitive rudeness to defined form and character; nor of the innovations or varieties in feeling or practice occasioned by the intercourse of hitherto strange and unknown nations.

The style of sculpture and the condition of the art at different periods among the Persians, the Egyptians, the Assyrians, the Etrurians, the Greeks, and the Romans, can fortunately be illustrated by reference to existing remains. Each of these people had their peculiar manner, which has given a character of *school* to their productions. In all of them the practice of art was more or less influenced by the priests, and by local and popular religious opinions; and it will be interesting to trace how far these influences affected the progress of sculpture, by restraining, as they did in some instances, its advancement towards perfection even as an imitative art; or in urging it forward, as among the Greeks, till it reached its highest excellence, by the union of subject, form, and expression, as a means of gratifying sense, exciting feeling, and elevating sentiment.
